A Belgian Prize Taken by an American Physician.—The competition instituted by L'Académie Royale de Médecine de Belgique in 1881, and continued through 1883, is closed, and the report of the commission of the Académie is made known. The question submitted was: "To Elucidate by Clinical Facts and by Experiments the Pathogeny and the Therapeutics of the Diseases of the Nervous Centres, and especially of Epilepsy." A number of memoirs were submitted, which were entered by European authors of pre-eminent rank in this department of research. The honors of the competition have, however, been awarded to an American physician, Dr. George T. Stevens, of New York. His memoir is the only one selected by the Royal Academy for publication, and the only one for which an award was made.

An Inconsistent Critic.—The *Weekly Medical Review* chooses to read us a lesson for publishing the fact that the St. Louis Medical Press Association invited a homœopath to its dinner, and intimates that The Medical Record is "uncertain, hybrid, narrow, provincial, and dishonest!" This is a rather sweeping charge, truly, to come from a quondam host. All that need be said is this: The hospitable editors of *The Review* invited to their dinner a homœopath. Yet it defends the policy of an association which forbade him membership, on moral grounds. Its course is very much like that of a man who invites a guest to his home, and then hurrahs for the crowd that would besplash him with mud as soon as he gets out of the door. We do not say that such conduct is "hybrid, narrow, or provincial," but it is, at least, not very consistent. We do not criticise *The Review's* list of guests, but rather praise its liberality, and are gratified for the courtesy of its editors.

Iodide of Ethyl is recommended by Dr. Bartholow in the treatment of brain syphilis when a prompt action of the iodine is desired.

The Woman's Medical College of New York.—Dr. H. M. Silver has been appointed Professor of Surgery in the Woman's Medical College of this city, and Dr. W. Meyer, Clinical Professor of the same branch.

The Medical Department of Niagara University.—Dr. W. A. Wheeler, Surgeon, United States Marine Hospital Service, has been appointed Professor of Surgery in the above institution, vice Dr. W. S. Tremaine, resigned. Dr. C. M. Daniels has been appointed Professor of Anatomy, vice Dr. William H. Heath, resigned.

The Abuse of Medical Charity.—On the ground, we presume, of the acknowledged fact that there is an excessive and pauperizing amount of medical charity in the larger cities, the Erie County Medical Society recently voted to oppose the granting of any appropriation of money for dispensary purposes by the Board of Supervisors of the county.

A Combined Board of Medical Examiners Wanted in California.—The State of California has a medical registration law which creates three Boards of Medical Examiners—one regular, one homœopathic, and one eclectic. Each board licenses the physicians who practise in these respective "schools." The plan does not work well, and the *Pacific Medical and Surgical Journal* urges the substitution of a single combined board.

Deciding against a New Medical College.—The Committee of the Medical Society of South Carolina, to whom was referred the question of the establishment of a medical school in connection with the University of North Carolina, reported that "there is no necessity for the addition of a medical department to the State University, and at present the scheme is utterly impracticable."

Enforcing the Medical Law in New York.—A long-haired, elderly man, calling himself Dr. George R. Harding was arrested on July 12th on a charge of practising medicine without a license. He is the head man of an "Indian village," encamped at Eighth Avenue and One Hundred and Twenty-eighth Street, from which placards are distributed advertising the cure of all diseases by means of "Indian Sagwa." An agent of the County Medical Society took his son, aged eight years, to the village for treatment on Friday. The "doctor" said that the boy had eczema, and sold the father some "worm-killer" and a bottle of ointment. In court he said that he was only an agent for a patent medicine firm, but he was held for $300.

A Pasteur Institute has been founded at Milan, under the direction of Dr. Barattieri.

Dr. Brown-Séquard has at last been elected a member of the Paris Académie des Sciences.

To Make the Punishment Fit the Crime.—The papers circulate the following story about an English surgeon. We are glad that such things do not occur in this country. An English surgeon a few days ago performed an operation on a little boy. The operation was comparatively trifling. The mother and the father and the little boy were in the surgeon's house just a quarter of an hour. "What is your fee?" said the father. "A hundred guineas," was the reply. The father was startled, and said he had not a hundred guineas. "Oh! then I will take fifty guineas." "But I cannot afford it," said the father; "and had you told me what your charge would be, I would not have come." "Then I will take twenty-five guineas." After a little more delay the surgeon took ten guineas on account.

Influencing Sex in Utero.—Dr. Alfred L. Carroll writes: "The letter of Dr. William H. Cook, under the above heading, in your issue of the 10th inst., while it recites some interesting coincidences, does not seem quite in accord with 'the sum of the information' accessible to the 'profession at large' in relation to the

subject in question. Aside from any argument based on the comparatively limited experience of individuals, it is certain that in the vast majority of marriages the first cohabitation occurs at a time when, according to Dr. Cook's hypothesis, a male child should be the fruit; but in the accessible statistics of nativity the male births of primiparæ outnumber the female by only about ten per cent. It is, of course, impossible in most instances to determine the particular act of coition which has caused impregnation, and the preponderance of males in still-births must be to a considerable extent placed to the account of primiparæ; but there still remains a sufficient multitude of first-born females to cast doubt upon any relation between sex and time of conception. Moreover, the idea advanced by Dr. Cook is not borne out, as far as my observation goes, in the lower animals, especially in the case of dogs and horses, where the time of intercourse can be positively ascertained. I should not trouble you with this note were it not that the embryological point involved is important, and that its scientific consideration demands more data than we yet possess."

Squier Littell, M.D., of Philadelphia, who died at Bay Head, N. J., recently, aged eighty-two years, was a member of the Philadelphia City and County Medical Societies, of the College of Physicians, and a licentiate of the Academy of Medicine of Buenos Ayres. His contributions to medical literature, extending over a period of fifty years, were very many. In 1828–29 he edited *The Journal of Foreign Medicine*. His most important work was his "Manual of the Diseases of the Eye," which was issued both in this country and England. He edited the American reprints of "Walton's Ophthalmic Surgery." For thirty years he was surgeon to Wills Hospital, Philadelphia.

Those St. Louis Pictures.—Dr. William A. Hammond was the only New York physician who was honored with a portrait and biography in the daily papers of St. Louis during the last meeting of the American Medical Association at that place, so says *Daniel's Texas Medical Journal*. We retract our intimation that New York was slighted.

The United States Naval Medical Department.—A correspondent of the *Globe-Democrat* has set in circulation the following account of the Medical Department of the United States Navy. The statements are certainly much exaggerated. He says: "The position of surgeon in the navy is not an enviable one. The examination that applicants are required to undergo is very rigid, and, as a rule, physicians who are capable of passing the ordeal can find fields for their usefulness more congenial to their taste and very profitable to them by engaging in private practice. When a physician obtains a position in the navy he is assigned to the steerage, without rank, and is given an ordinary salary. In the army it is the reverse. When a physician joins that branch of the service he is commissioned a second lieutenant and is paid accordingly, and commands all the respect the position is entitled to. The result is that there are no vacancies in the army, while there are over two hundred candidates for positions. In the navy there are fifteen vacancies, with no applicants to fill them."

The Cholera is extending quite rapidly in Italy. A large number of cases are reported daily at Brindisi, Latiano, and Fontana.

We perhaps owe an explanation to our esteemed contemporary, *The Medical and Surgical Reporter*, for blaming its editor because his name appeared in the papers and in advertising pamphlets indorsing a proprietary and specific mineral-water. The Old Code does not expressly forbid this practice. The New Code does do so. Perhaps this is the reason that our staid contemporary has shown such aversion to the latter. The New Code says: "It is reprehensible for physicians to give certificates attesting the efficacy of wines, mineral-waters, health-resorts," etc.

Regulating the Practice of Medicine in North Carolina.—*The North Carolina Medical Journal* comments in a courteous and judicial manner upon the letter published recently in The Record by a "North Carolinian." The editor says: "We think that 'North Carolinian' has not understood the temper and disposition of the medical profession in the State if he believes that anything was contemplated by them save to have a law enacted which would give to the people of the State better doctors. We know, also, by some of his allusions that he has in his mind certain *soi-disant* leaders who do not represent the profession. It is very humiliating, not more to the representatives of the younger than of the older class of physicians, to see exhibitions of gross ignorance upon the witness-stand and elsewhere, but this does not justify the sneer which he cast upon all of the older men of the profession in the State."

Explosion at a Hospital.—One of the wards of the Portsmouth (Eng.) Military Hospital was wrecked not long ago by a gas-explosion. There were several patients in the wards, but they all escaped injury. One man, who was delirious, tried to jump out of the window, and was with difficulty restrained.

An English Professor's View of the Importance of Latin.—Professor M. Charteris, of Glasgow, in an article on "Prescriptions," in the *Provincial Medical Journal*, says: "Every qualified medical practitioner, on being called to a patient, is expected, in addition to dietetic rules, to embody his ideas of medicinal treatment in the form of a prescription. This prescription is written out in Latin—a language which should be familiar to every educated man. It is the masonic badge of our profession, and he who is ignorant of it and its grammatical construction is an interloper in the practice of medicine, although he may be dubbed M.D. by a university, or receive the license of physician and surgeon by conjoint corporations."

A Curious Discovery, bearing upon the Phenomenon of Sleep, has been made by Mons. E. Bouchard (*Comptes Rendus*, cii., p. 727). Some experiments made by him on the difference in urine produced during sleep and during wakefulness have shown that the former has a convulsive action on animals, and the latter a narcotic one. He therefore concludes that the body while awake elaborates a substance which causes sleep, and when asleep produces a something which can cause muscular shock and provoke wakefulness. It may be hoped that

further investigations will enable him to detect the substance causing natural sleep, so that it may be turned to account in therapeutics.

The Use of Condiments by the Sick.—Dr. William A. Hammond says, in *The Journal of Reconstructives:* "It is rarely the case that sufficient attention is given to the use of condiments in the sick-room; they are often either altogether excluded, or the patient is allowed to take them at his discretion, whereas much benefit will frequently be obtained by the judicious employment of these important agents. In certain low fevers of typhoid type, and in almost all malarial disorders, condiments may be largely used with advantage. Probably no one of them is more generally efficacious than black pepper. Mustard is also frequently relished, and we all know how grateful to us in our illnesses a little vinegar has been. In inflammatory affections of the stomach and bowels the stronger condiments, such as pepper, cayenne, mustard, and horseradish, are seldom admissible; but many cases of diarrhœa are very decidedly benefited, especially when they occur in persons who have somewhat run down in general health, by black pepper, cayenne, or mustard, taken in quantities far above those which a healthy person would be likely to ingest. I have frequently known severe cases of diarrhœa to be cut short by a few doses of twenty or thirty grains each of cayenne, taken either in a little water or syrup. Black pepper is well known to be a remedy of no mean power in the common fever and ague of this country; it will often cut short attacks with as much promptitude as would large doses of quinine."

Dietetic Fallacies.—1. That there is any nutriment in beef-tea made from extracts. There is none whatever. 2. That gelatine is nutritious. It will not keep a cat alive. Beef-tea and gelatine, however, possess a certain reparative power, we know not what. 3. That an egg is equal to a pound of meat, and that every sick person can eat them. Many, especially those of nervous or bilious temperament, cannot eat them; and to such, eggs are injurious. 4. That because milk is an important article of food, it must be forced upon a patient. Food that a person cannot endure will not cure. 5. That arrow-root is nutritious. It is simply starch and water, useful as a restorative, quickly prepared. 6. That cheese is injurious in all cases. It is, as a rule, contra-indicated, being usually indigestible; but it is concentrated nutriment, and a waste-repairer, and often craved. 7. That the cravings of a patient are whims and should be denied. The stomach often needs, craves for, and digests articles not laid down in any dietary. Such are, for example, fruit, pickles, jams, cake, ham, or bacon with fat, cheese, butter, and milk. 8. That an inflexible diet may be marked out, which shall apply to every case. Choice of a given list of articles allowable in a given case must be decided by the opinion of the stomach. The stomach is right, and theory wrong, and the judgment admits no appeal.—*Technics.*

Notes on Some New Remedies.—Some physiological experiments made with the dog mercury (*Mercurialis perennis*), by Dr. Hugo Schulz, to ascertain whether the plant really possesses the poisonous properties attributed to it, show that although in no case it proved fatal, yet it produces a paralyzing action on the muscular apparatus of the bladder, and decreases the peristaltic action of the bowels, while at the same time the quantity of urine excreted is considerably increased, and more or less diarrhœa is present. A new alkaloid has recently been extracted from manaca-root, and is named *francisceine*, after the plant which yields it, which is *Franciscea uniflora.* The alkaloid is said to have a very powerful diuretic action, and to possess, in addition, emmenagogue and diaphoretic properties. Under the name of *Pingo pingo* a new drug has lately been imported into Hamburg from Chili. It has been identified as *Ephedra andina* (*Gnetaceæ*), and, like other species of the same genus, is reputed to possess diuretic properties and to be useful in certain diseases of the bladder. A narcotic principle, to which the name of *Kelline* has been given, has been obtained by M. Moustapha from the *Ammi Visnaga*, the El kellah of the Arabs of Algeria. It is an umbelliferous plant, having an aromatic taste, the seeds of which have been used as a diuretic and aperient, and to form a mouth-wash in gingivitis and dental caries. The narcotic principle was found, in the experiments made upon animals, to cause vomiting, paralysis of the hinder extremities, slowing of the respiration, and irregularity of the heart's action.—*Prov. Med. Journal.*

A Source of Vegetable Musk.—Dr. A. G. Chase, of Millwood, Kan., writes: "I would like, through The Record, to call the attention of pharmacists to a probable new source of vegetable musk, viz., the tips or latest growth of watermelon-vines. I have not attempted to extract it, but each year, for the past six or eight, I have had it in mind to call public attention to it. On the fresh growth of the vine the pure musky odor is very strong—almost overpowering; and if easily extracted, the abundant source of supply would admit of this somewhat valuable medicine being sold more cheaply."

Galen on the Treatment of Obesity.—"The best method of getting thinner consists in gradually withdrawing from the body that whereof there is superfluity, and in strengthening at the same time those parts which had been expanded. Bodily exercise will undoubtedly prove very advantageous, as we see stout horses getting lean by heavy work. Thus, likewise, those will never grow fat who are obliged continually to toil with hard labor. This, however, requires great precaution, it being certain that fat people frequently run danger of death when attempting violent bodily exercise." And Galen says: "Regular alvine motions, energetic bodily exercise, a moderate life, a diet which, although satiating, yields but limited nourishment; which explain why Hippocrates advises stout people wishing to grow thin to dine on vegetables cooked with fat, in order that they may become satiated by a small quantity of food."

Better than Thanks.—The Dental Association of the Province of Quebec held its annual meeting in the hall of Laval University, in Montreal, which was placed at its disposal by the authorities of the University. At the conclusion of the session, instead of the ordinary vote of thanks, the Association expressed its gratitude by a gift of fifty dollars to the medical library of the University.

Reports of Societies.

KENTUCKY STATE MEDICAL SOCIETY.

Thirty-first Annual Session, held at Winchester, Ky., June 23, 24, and 25, 1886.

Dr. John L. Taylor, of Bowling Green, read a paper on

INJURIES OF THE HEAD.

He reported the case of a boy who received a severe blow on the head.

Dr. J. H. Letcher, of Henderson, reported a case of

MANIA AFTER CATARACT OPERATION.

He operated one year ago on a well-preserved old gentleman, Mr. B——, a farmer, who had been blind for some time from a mature cataract of both eyes. Shortly after the operation Mr. B—— became insane, and thought everyone was mistreating him. He was without fever and the pulse was normal. Morphia gave relief. He thought it might be due to the drops of atropia instilled into the eye. There were no other signs of atropia-poisoning present. He queried could this disturbance be due to the closure of the eyelids and the effect of the bandage; could it be due to confinement, the forced recumbent posture in a man wont to be active, or might the unaccustomed noise about the house be to blame.

Dr. E. Williams reported a similar case.

Dr. J. G. Cecil, of Louisville, read a paper on

PUERPERAL FEVER.

He paid especial attention to the treatment. Puerperal fever he considered puerperal septicæmia, or surgical fever allied to the puerperal state. No better being given we may pin our faith to micrococci as the most probable cause. Prevention is the great thing. Absolute cleanliness in every detail. We should give attention to ventilation and sewerage. Nearness to water-closets is prejudicial. Bathing the external genitals with antiseptics is a good practice. The proper care of the uterus in a case of labor in private is to let it severely alone, being always ready for an emergency. The indications for vaginal injections should be present before this dangerous practice is undertaken. In such proportion as the case has been difficult or protracted is the demand for intra-uterine injections. He did not wish to convey the idea that vaginal or uterine injections will always prevent puerperal fever.

Management: Improvement in this line has been perfectly wonderful. Temperature, pulse, and odor of the lochia are the indications for the douche. The solution *par excellence* is bichloride 1 : 1000 to 1 : 10,000, always given hot.

SECOND DAY—EVENING SESSION.

Dr. J. A. Larrabee, of Louisville, made the

REPORT ON PEDIATRICS.

In the broad and open field of pediatrics we have great opportunity to use preventive medicine. Two-thirds the whole number treated in his children's clinic are the effects of syphilis. He reviewed methods of acquiring syphilis. Within four months I have treated two young men with chancre on tongue, four young ladies with chancre on lips, latter by kissing. As to mercury, it does not differ what preparation you use, as it acts as the bichloride. He greatly prefers the inunctions of the old-fashioned blue ointment. He next discussed the subject of medical legislation, which he thought must be the result of education, and where is the education to come but through the profession? We have not yet attained the medical wisdom of Solomon nor the sanitation of Moses. He compared the present rage about hydrophobia to the amount of damage done to humanity by hydrophobia and syphilis. How often do we hear ringing in our ears at the marriage ceremony these words, "who knows aught," etc., when we know all too much. The licensing of prostitutes for one year in St. Louis reduced syphilis thirty-five per cent. Had it been continued what would have been the result?

Dr. Ap Morgan Vance, of Louisville, read a paper on

THE ORTHOPEDIC SURGERY OF TO-DAY.

He said that the orthopedist had been accused of going outside of his specialty. This belief grew from an ignorance of the field of the orthopedist. He gave as a fair definition of the word the following: That branch of surgery which takes into consideration the treatment, cure, or palliation of diseases which tend to cause deformity of bones and joints. He discussed spinal caries, diseases of the hip-joint, elbow, burns, cicatrizations, and congenital deformities. In treatment he gave special laudation to rest.

Dr. George W. Ryan, of Cincinnati, said he was sure that every orthopedist will thank Dr. Vance for his broad definition of the work of the orthopedic surgeon. In common with other specialists the orthopedist is at times accused of stepping outside the limits of his work if he resorts to operative or other measures supposed to belong to the general surgeon. But as the reduction and cure of deformity is his profession, the means which are employed, be they the knife or the apparatus, have only a scientific interest.

The paper has much in it on which we can all agree, and the author is to be congratulated on the excellence of his result in the case reported. But there are some statements to which I might take exception, notably those concerning the treatment of lateral curvature of the spine and the rachitic deformities.

I should be very far from agreeing to what the author justly terms the bold statement that the

MECHANICAL TREATMENT

of lateral curvature is unsurgical and cruel. I do not doubt he may find authority for this, but the judgment of most orthopedists is decidedly the opposite.

The mechanical treatment may possibly be considered of only secondary importance to the gymnastic exercises, the faradism, and the massage; but I believe it is of great value in securing a good result or in preventing an increase in the curvature. Certainly in my own case I have no reason to be dissatisfied with it. The

PLASTIC DRESSINGS,

so generally used, may certainly be considered unsurgical and cruel, for they are neither scientific nor satisfactory.

The value of proper and systematic exercise with

FARADISM AND MASSAGE

is unquestioned. Mechanically I have been using for the past two years elastic force over the convexity of the curve. This is obtained by using the heavy elastic webbing, such as the manufacturers of artificial limbs employ in their work.

A simple, light, steel frame is employed in order to get the fixed points. This is held by the ordinary corset front to the patient's body, a light pad being placed over the point where the pressure is to be made. The pressure is even, yielding to a certain extent, and its use is not followed by any pain. This apparatus, in conjunction with the adjuvants mentioned, has done excellent service. In one case of typical rotary lateral curvature it has been diminished a little more than one-third, and in others the treatment has been the means, in my belief, of arresting the growth of the curvature.

The views of Mr. William Adams, who is always con-

servative and always sound, are entitled to the very highest consideration. He says, in the last edition of his work on this subject (p. 280): "I can only say that after an experience of thirty years I shall adhere to the employment of spinal instruments in many cases, with the object and within the limit I have defined."

Concerning the statement that the rachitic deformities, such as bow-leg and knock-knee, should be held over until from three to five years for an osteotomy, I should say this was not altogether wise. Of course, if the bones have become thoroughly hard, osteotomy is proper, and, in fact, is the only means we have of correcting the deformity. But if the bones have not become hard and unyielding, the correction of the deformity by means of proper apparatus is about the easiest and simplest problem that presents itself to the orthopedist. Why we should wait for a year or two in order to perform an operation, when simple mechanical means will accomplish the same purpose without pain or danger, I confess I cannot very clearly see. Neither is the osteotomy devoid of all danger, though the per cent. of good results is very large; but I wish to be understood as appreciating the great value of the operation, and only question the wisdom of its employment in every case of curved limbs.

FRIDAY, JUNE 25TH—THIRD DAY—MORNING SESSION.

DR. J. MORRISON RAY, of Louisville, made the

REPORT ON OTOLOGY.

He referred to the rapid advance made in recent years in the knowledge of ear diseases. During the past year numerous valuable additions to the literature of this important branch of medicine have been made. One of the most noteworthy of these is a revival of the operation of multiple punctures of the membrana tympani in the treatment of certain cases of persistent catarrhal deafness. He said that when this operation was first introduced the profession was not in a position to discriminate between the proper and the improper cases, thus the method fell into disrepute. But since the correct interpretation of the tuning-fork test has been made, the cases that are apt to be benefited by this operation are more intelligently picked out. He, however, agreed with the opinion expressed by Schwartz and Von Tröltsch, that among the many favorable results none can be said to give sufficient evidence of its real value unless the patient has remained for a long time under observation after the operation. The modifying influence of syphilis on ear diseases, and the importance of its recognition when possible, was spoken of, and a case to the point cited. He agreed with Bomeray that malarial ear diseases do not exist, but that the malarial poison often exerts an influence on the course of ear diseases. The importance of a recognition of disease of the nose and naso-pharynx in cases of aural trouble was emphasized. The report of Bezold on the examination of the ears of school children was noted and attention drawn to the following statement: "My statistics show that the mental development of the individual suffers a limitation corresponding to the degree that his hearing power is diminished." Of the new drugs, he said, cocaine had not been as great a boon to sufferers from aural diseases as to those with eye troubles. The peroxide of hydrogen was spoken of in high terms, and it was claimed to be one of the best agents in the treatment of suppurating ears. Iodol was extolled, and was said to act promptly in stopping the discharge.

DR. ALLEN KELCH, of Louisville, read a paper on

THE CAUSE OF REGULAR ASTIGMATISM.

After calling attention to the coarse anatomy of the refracting media, and showing that three out of the four of them can be changed in form by reason of the absence of muscular fibre in them, in a passive manner only, he called attention to the fact that the faculty of accommodation resides in the changes of form, either active or passive, of the crystalline lens; that this being accepted as a fact, it must at once be admitted that regular astigmatism, as it is constantly met, cannot reside in the crystalline lens, for the reason that regular astigmatism is a constant, invariable quantity of defect of refraction, capable of measurement and correction by one unvarying, unchangeable lens; whereas, if it resided in the crystalline lens, it must and it could not do otherwise than vary with every varying degree of accommodation exercised. By the process of exclusion the aqueous and vitreous humors were incapable of being the seat of regular astigmatism, leaving only the cornea to be considered.

He showed how this medium, by reason of its projection and its position, must be attended in form by the pressure and the action of the eyelids in this, that it is compressed in the vertical meridian while it is lengthened in the horizontal, correspondingly increasing its refracting power in the vertical and decreasing its power in the horizontal. This being true, it must follow, as a natural consequence, that astigmatism, requiring a positive cylinder for its correction, must have that cylinder so placed as to increase the refraction in the horizontal meridian, inasmuch as the horizontal indicates the direction in which the cornea exerts the least refracting power. In order to add to the refraction in this meridian it is, therefore, necessary to place a positive cylinder in the vertical position.

Does large experience in the correction of regular astigmatism indicate this to be true? Experience follows the channel indicated by this theory most admirably, as he then proceeded to show.

In a recorded experience of 512 consecutive cases of astigmatism, occurring in the practice of Dr. Dudley S. Reynolds, who kindly permitted him to copy his notes, he found that in 448 cases, occurring in the right eye, there was required for correction, either alone or in combination with a spherical glass, a positive cylinder in the vertical meridian in 340. By a moment's reflection it will be seen that those cases requiring a negative cylinder in the horizontal meridian differ from the foregoing in degree only, and not in kind, and of these there were 37, making a total of 377.

In the left eye astigmatism existed in 452 cases, and required the positive cylinder in the vertical position in 337, and the negative, in the horizontal meridian, in 37, making a total of 374.

Of the 66 cases requiring correction in other meridians in the right eye, 23 required correction in meridians approaching within 10° of the vertical or the horizontal, which cases add their force to this theory, and swell the whole number to 400 cases out of 443 in the right eye. In the left eye those approximating within 10° numbered 32, making a total of 406 in the left out of 452.

This yields, sustaining this theory, 90 per cent. in the right eye, and 89.82 per cent. in the left eye.

The nature of the refracting media shows that regular astigmatism can exist only in the cornea, and the uniformity with which it here exists in a single direction, conforming exactly to what might be expected to be produced by the pressure of the lids, leads at once to that as the operating force in its causation.

He therefore derived the following conclusions:

(*a*) Regular astigmatism is due to changes of the spherical form of the cornea.

(*b*) The cornea has its contour altered by the pressure of the lids, and in this pressure we find the cause of regular astigmatism.

A paper was read by DR. WM. CHEATHAM, of Louisville, entitled

NASO AND NASO-PHARYNGEAL REFLEXES.

The paper dwelt principally upon hay fever. Dr. Cheatham uses electrolysis in reducing nasal hypertro-

phies. He claims that it is as rapid and the action is very much less dangerous than the galvano-caustic or other acids. The after effect is much more satisfactory. It leaves no cicatrix but at the point of the entrance of the needles. He uses cocaine to differentiate between true hypertrophy and engorgement. He locates sensitive areas in some cases in the larynx, pharynx, and conjunctiva. He also referred to the frequency of trigeminal cough and its proper management. He divided the causes of hay fever into: 1, External irritation; 2, predisposition; 3, vulnerable or sensible area. Especial attention was paid to the latter. He recommended to find this point and destroy it. He dwelt at length on the nerve supply of the nose.

Dr. J. A. Stucky, of Lexington, made the report on

RHINOLOGY,

which was the first report on this subject made to the Society.

The report was discussed by Dr. J. M. Thompson, of Richmond.

Dr. Edward Von Donhoff, of Louisville, read a paper entitled

CLINICAL DATA WITH REFERENCE TO A NEW METHOD IN THE TREATMENT OF FRACTURES.

Dr. Samuel E. Woody, of Louisville, read a paper on

THE REMOVAL OF HAIR BY ELECTROLYSIS.

On motion of Dr. S. Reynolds, of Louisville, the salary of the Permanent Secretary was raised from $50 to $100 per annum.

On motion, the thanks of the Society were tendered the President, the Committee of Arrangements, the citizens of Winchester, and the railroad companies.

The social programme consisted of a hop on Wednesday evening, and a banquet on Thursday evening, both very enjoyable. Kentucky can always be relied upon to do her share of hospitality.

The attendance reached 150.

Adjourned, to meet at Paducah on the third Wednesday in June, 1887.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, June 4, 1886.

F. P. Kinnicutt, M.D., President *pro tem.*

Dr. George L. Peabody read a paper (see p. 65), in which he reported cases of

ENDARTERITIS OBLITERANS,

accompanied by microscopic sections.

Dr. Sexton asked Dr. Peabody if he obtained any satisfactory results from the use of very considerable doses of iodide of potassium.

Dr. Peabody said that it was difficult to say whether *post hoc* was necessarily *propter hoc*, but in the case in which the patient recovered, recovery followed the use of iodide of potassium. When the lesion was syphilitic, he would suppose that iodide of potassium was indicated as much as in any other form of cerebral syphilis.

Dr. E. G. Loring thought that one of the chief points of interest in Dr. Peabody's paper was the elucidation of the fact that endarteritis may exist independent of syphilis. He was under the impression that this condition was seen in the eye very often, that there the endarteritis can be followed through years and the gradual obliteration of the vessel traced, and that finally the diagnosis can be confirmed by microscopical examination.

This disease occurs in young children, apparently as a regular inflammation which reduces the lumen of the vessel by some substance which is not atheromatous in the strict sense of the term, because the vessels of the eye are too small to be the seat of atheroma; but the material is so transparent as not to interfere with the appearance of the vessel, and there is apparently no change, except that the size is reduced and the walls are abnormally thick. These changes can be traced until, finally, portions are seen in which the lumen has been absolutely obliterated. In other cases there is a more active inflammation, and the arteries are changed into white cords, which can be distinctly made out as the result of endarteritis and periarteritis.

Dr. Loring was also much interested in the rapid recovery which sometimes takes place in cases with the symptoms which Dr. Peabody had related, and he would ask the doctor what, in his opinion, the exact lesion was that gave rise to the symptoms?

Dr. Peabody said that the explanation which seemed to him to be plausible, although purely theoretical, was, that in any vessel in which the lumen was already considerably encroached upon, there took place a spasmodic contraction of the muscle-cells in the walls of longer or shorter duration, and when this was relieved the blood again flowed to the parts to which the vessel was distributed.

Dr. Loring said that there were several cases on record in which spasmodic contraction of the arteries in the eye occurred, so that the vessels looked like mere threads. Graefe had reported a case on which he was about to operate when vision suddenly returned, showing that the condition must have been one of spasm simply. He had seen a case in which this would take place eight or ten times a day, and it was so distinct that the patient would watch and notice the blindness come on, and then observe it unwind and go again. Finally the eye went out altogether, and on examination he then found acute œdema of the vessel, which finally cleared up, when the endarteritis could be made out with slight hemorrhages, which were ultimately absorbed, and at last no vessels were left, neither veins nor arteries. He therefore thought that spasm of the small vessels would account for the sudden exhibition of the symptoms and their sudden disappearance.

Dr. Amidon asked concerning the condition of the heart in Dr. Peabody's cases.

Dr. Peabody said that it was normal, except in the first case, in which there was found very slight hypertrophy of the left ventricle. In that case also there was thinning of the cortices of the kidneys, and he regarded the hypertrophy of the heart as compensatory to the changes in the kidneys.

Dr. Amidon said that the reason he asked the question was, because it seemed to him that transitory aphasia and paralysis which occurred in syphilitics depended very much upon the condition of the heart. He thought that the symptoms could be better explained on the supposition that transitory weakening of the heart occurred, and lack of force sufficient to send the blood to the nerve-centres, than on the supposition that spasm of the arterial wall took place. Moreover, when the *intima* was so much hypertrophied, as it was often almost nodular, spasm of the *media* would perhaps be less likely to close the vessel than a weakened heart would be incapable of forcing sufficient blood through the narrowed lumen to supply the brain-substance. However, he did not wish to substitute one explanation for the other, but preferred rather to divide the cause of the disturbance between the two conditions.

Dr. Kinnicutt thought that Dr. Amidon's suggestion was rather contradicted by what occurred in certain patients suffering from renal disease, when the hypertrophied heart was doing its full work apparently, and yet the same train of symptoms were occasionally seen, and could hardly be explained except on the supposition of the occurrence of spasm of the blood-vessels. To be sure, there was a diseased condition of the blood-vessels, but the symptoms were more in harmony with the theory of spasm than with that of transient weakening of the heart.

The assumption of arterial spasm was also in harmony with the use of therapeutical measures which directly relieved the arterial spasm. Still the suggestion made by Dr. Amidon was worthy of full consideration.

Dr. Amidon asked if nitrite of amyl had been used in this condition.

Dr. Loring remarked that it had been used by Dr. Noyes in a case with wonderful effect, as it would clear up the blindness almost instantly. However, the weakened heart doubtless exerted an important influence.

Dr. A. B. Ball then read a paper, published in a previous issue, entitled

TWO CASES OF MYXŒDEMA, WITH REMARKS ON THE PATHOLOGY OF THE DISEASE.

Dr. R. W. Amidon said that he had been very much interested in Dr. Ball's paper, especially as he had the opportunity to see the first male case recorded, at Charcot's clinic in 1880, when Charcot told him that he had noticed the disease twelve years before that date, but unfortunately had never published anything concerning it. The patient was a male, aged fifty-seven, whose symptoms commenced in 1873, and consisted of swelling of the face, slight swelling of the extremities, with loss of appetite, etc. In 1878 Gumbold, his assistant, very carefully studied the case, and at that time the patient had the peculiar waxy facies, swollen tongue, eyes half closed, slow speech, husky voice, lips everted, teeth had all fallen out, but little hair remained upon the body, skin rough and scaly, mental condition slow, and progressive diminution of all the forces, with an apathetic condition, pain in the lumbar region, very sensitive to cold, etc. He improved on a milk diet, and it is not yet absolutely sure that it is a case of myxœdema, because the patient is still living. The fact, however, that he did improve is not evidence that it is not a case of myxœdema.

The experiments of Horseley were interesting with reference to the etiological features of the disease, as the group of symptoms produced by extirpation of the thyroid in animals were very much like those in the reported cases of myxœdema, and reminded him very much of some cases of paralysis agitans without tremor, also described by Charcot; but in these cases the patients complain of sensation of heat, and there is an abnormal temperature.

As to the primary etiological condition, Dr. Amidon was inclined to agree with Dr. Ball that it is in the thyroid gland, and especially because recently he had a case of perfectly typical sympathetic paralysis of one side, with atrophied thyroid, but no myxœdematous symptoms whatever.

Dr. Loring said, with regard to the condition of the arteries of the eye in the cases examined with the ophthalmoscope, that it might be there was deposit there, and it might also be that the reduction in size was not real, but was apparent on account of the dilatation of the veins. He had seen one case of myxœdema, that of a woman, in which he could recognize distinctly a peculiar ophthalmoscopic appearance, consisting of a moderate degree of neuro-retinitis, with much enlarged veins, and but slightly reduced arteries. In the case reported by Dr. Wadsworth there was an atrophied optic disk, and in the seven cases reported by Dr. Little there were no changes in the arteries.

Dr. C. L. Dana did not see how we could escape from the conclusion reached by Dr. Ball, although it was difficult to understand how so small a body as the thyroid could exert such an influence on the nutrition of the body.

Ever since he read the experiments made in connection with this affection, he had endeavored to ascertain whether or not there was any disturbance of the thyroid in cases of organic and functional diseases of the nervous system. In cases of chorea it was not infrequent to find the thyroid enlarged—in five to ten per cent. of the cases there was a marked enlargement—which disappeared when the chorea was recovered from. He thought that he had also detected change in the size of the gland in several cases of insanity; in some cases enlarged, and in some diminished, in size. He believed that the subject was worthy of investigation.

Dr. G. A. Peters said that the histories of Dr. Ball's cases brought vividly to his mind a case which was under his observation several years ago, but at which time he did not know the nature of the disease.

Dr. Kinnicutt referred to a case which he saw quite frequently for many years without recognizing it. With regard to the thyroid, it was not enlarged, and he had thought that it was either normal or slightly reduced in size. The patient still enjoys life fairly well, and is in fairly good general health, and her condition has not changed apparently for five years.

The Society then adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

HOSPITAL SUNDAY—THE NEEDS OF THE HOSPITALS AND NEW MODES OF MEETING THEM—CLINICAL FEES—PAYING PATIENTS—THE LATE MR. ROYES BELL—THE MEDICAL BILL—THE HAMILTON ASSOCIATION FOR PROVIDING TRAINED MALE NURSES.

London, June 28, 1886.

Yesterday was Hospital Sunday, and collections for the medical institutions of the metropolis were accordingly made in most of the leading churches and chapels of all denominations. This year an innovation is to be made, for not only the religious, but the play-going public, are to be persuaded into donating. A number of the collecting-boxes have been affixed in the theatres and other places of amusement. The "mechanical beggar" in the Colonial and Indian Exhibition may be expected to produce a good harvest. This is a collecting-box with a little oscillating ticket attached to it, bearing a request to give. On dropping a penny in, a little plate rises up with "Thank you" inscribed on it. It is the invention of a medical man. These—and all other means of extracting money from those who have any to spare—are all sadly needed, for truly the hospitals of London are in a poor plight. Forty thousand pounds are needed this year to make good the deficit of the hospitals and dispensaries of London. It is now some years since an entire block of St. Thomas' Hospital was, under the name of St. Thomas' Home, appropriated for the use of paying patients. A year or two ago Guy's Hospital was driven to a similar course, and the announcement was made that paying patients would be received at a charge of a guinea a week, this being but half the amount charged in St. Thomas' Home. It was intimated that the authorities of Guy's Hospital were obliged to adopt this method of adding to their finances, in consequence of the depreciation in the value of land, which had caused a serious diminution in the income of the hospital. Guy's Hospital has a magnificent endowment, but it is largely vested in landed property. Considering the impecunious condition of so many of the large general hospitals, it really seems a fair question whether it would not be desirable to appropriate for the hospital funds the large sums paid by students for attending hospital practice. At present this is nearly all divided among the physicians and surgeons, as fees for teaching. A physician or surgeon attached to a large hospital, therefore, although he receives no direct remuneration from the hospital for his services, gets a very handsome equivalent in the form of students' fees. For these he is supposed to give a *quid pro quo* in the shape of bedside teaching, but the quantity and quality of the latter is by no means always proportionate to the amount

paid for it. The instruction given varies greatly at different hospitals, and with different teachers. In some cases it is very excellent, while in others it is but meagre and indifferent. Most of the physicians and surgeons to the in-patients of our large hospitals have reached an age and attained a position such that they do not really need the fees they receive for hospital teaching. Their juniors, in the out-patient rooms, be it remembered, get no fees for the teaching they give there. The clinical material is, of course, not so valuable as that in the wards, but it has a value of its own, and much valuable instruction is often given by the aid of it. The work is, at any rate, as hard as that of the wards, and those who do it may be presumed to need remuneration more than their seniors.

One device, which has been adopted very largely of late years, is to make the patients pay. I have mentioned above the system of receiving paying in-patients. This is now in force in a large number of the smaller hospitals. At many institutions, though, out-patients are also required to contribute, and in many cases do to a very large amount annually. This method of raising money for hospitals and dispensaries was formerly much decried, but at present, whether right or wrong, it is a well-established procedure. Naturally, under such circumstances, many patients of a better class betake themselves to a hospital or dispensary when they find that, by making a small weekly payment, they can be relieved from the trouble and worry of obtaining a governor's letter of recommendation. Not without some truth does the general practitioner complain that the hospitals rob him of his patients. The special hospitals have displayed the greatest ingenuity in extracting payments from patients. In some of them the pay plan has been erected into a veritable system, and a sliding-scale constructed, according to which a patient is required to pay a sum varying from one to five shillings a week, according to his or her means. In this line of business the Throat Hospital, Golden Square, is *facile princeps*, for it has carried the paying system to such an extent that it is nearly self-supporting, and almost independent of donations and subscriptions. Indeed, I believe the last balance-sheet actually shows a profit on the working expenses.

Yet another hospital surgeon has passed away almost before reaching middle age. I refer to Mr. Royes Bell, Surgeon to King's College Hospital, who died at the early age of forty-four. Mr. Royes Bell was born in Australia, but came to Europe early in life, and was educated at King's College. In 1870 he became a member of the surgical staff of King's College Hospital. For many years he assisted the late Sir William Ferguson very largely in his private practice. Mr. Bell furnishes yet another example of long years of patient toil in out-patient practice, ending in death before the well-earned reward of so many years' work can be reached.

Contrary to expectation the Medical Bill has passed. It will not very materially alter the present position of practitioners in this country. Its most noteworthy features are those permitting the registration of foreign degrees (the holders being already registered in virtue of the possession of a British qualification), and of diplomas in sanitary science.

The first annual meeting of the Hamilton Association for Providing Trained Male Nurses was held on Wednesday last. Sir Thomas Crawford, K.C.B., Director-General of the Army Medical Department, presided and moved the adoption of the report. This was seconded by Sir Joseph Fayrer, and carried unanimously. Several gentlemen afterward addressed the meeting and spoke in favor of the movement. The report showed that during the past year satisfactory progress had been made. The male nurses supplied by the Association had given satisfaction in nearly every case, not only to their patients but also to the medical men under whom they had worked. The position of the Association appears to be unique. Although there are numerous institutions in London for supplying female nurses, in no one, although many profess to supply male attendants, is there a department for male nurses who have been through a systematic course of hospital training. Only trained male nurses are employed under the Hamilton Association. It should be added that the Association is not established as a commercial undertaking, or for the purpose of profit or gain.

OUR PARIS LETTER.

[TUBERCULOSIS IN CHILDREN AND INFANTILE HEREDO-TUBERCULOSIS—"THE TOLERANCE OF THE ORGANISM"—A FATAL BILIARY CALCULUS—THE MEDICAL OPPORTUNITY.]

As a corollary to your editorial note in THE RECORD of June 19th, anent tuberculosis in children and the question of congenital tuberculosis, I may here give a summary of a note read by Dr. Landouzy at the Medical Society of Hospitals on the same subject. The author's conclusions are: That tuberculosis in infancy—that is, from birth to two years of age—is more frequent than it is said to be. It does not often present any other localization than a broncho-pneumonia. The latter is sometimes simple in appearance, and can be proved tuberculous only by bacteriological examination; at other times, on the contrary, it coexists with other lesions manifestly tuberculous. Tuberculosis is transmitted to the new-born infant either by mediate contagion or by heredity. Hereditary tuberculosis is transmitted by the grain. The bacillary proof of heredo-tuberculosis has been given by Johne. This question of the heredity of the grain shows how difficult is the prophylaxy of infantile tuberculosis, and the author asks, if much could be done against tuberculosis by contagion, what can be done against infantile heredo-tuberculosis?

At the same meeting of the Medical Society, Dr. Robin communicated a curious example of what he termed the "tolerance of the organism," or the impunity with which a person can live even with grave lesions in the interior of the body. The subject was an old woman, seventy-nine years of age, who died in his ward at the hospital from the sequelæ of pneumonia. Dr. Robin stated that on different occasions he had treated the patient for slight attacks of bronchitis, but independent of these occasional attacks her life was passed without her ever having felt herself positively ill; nevertheless, at the post-mortem examination of her body, Dr. Robin found, in the first instance, a double aneurism of the abdominal aorta, which, however, was cured spontaneously. He then discovered considerable dilatation of all the biliary ducts, extra- and intra-hepatic, which were filled with calculi of different dimensions.

On the same occasion Dr. Legroux exhibited a voluminous biliary calculus, which was found in the dejections of a patient affected with hepatic colic. The stone measured 33 mm. in height and 22 mm. in breadth. Its composition presented nothing particular.

The *Semaine Médicale* has published a note from M. Rivolta, Professor at the Veterinary Institute of Pisa, in which the author gives an account of his researches on rabies, the microbe of which he believes he has discovered.[1] In adopting a special method of coloration he has succeeded in establishing the constant presence of a parasite in this malady. The following is the method adopted by the professor: After having allowed the spinal marrow, the medulla oblongata, and the other organs of animals which died from hydrophobia to harden in alcohol, he cuts them up into fine pieces, which he afterward puts into chloroform, where they are left for twenty-four hours, to rid them of the fat which they might

[1] The inference [illegible] though but partially.

contain. He puts them back into alcohol, and then into a mixture composed of ten parts of an aqueous solution of caustic potash (ten per cent.), three parts of distilled water, and three parts of glycerine, where they are left five or six hours, or even more. This done, the pieces are put into a solution of methylene blue, in which they are left for a few minutes, until they have been entirely tinted blue. After being washed with distilled water, they are placed on a plate of glass (object-glass), where they are allowed to dry slowly at a mild heat. The preparation is finally completed with Canadian balsam dissolved in chloroform. If, at this moment, the preparation is examined, it will present a diffuse coloration, but it is easy to obtain the coloration special only to bacteria by exposing, with precaution, the object-glass to the flame of a spirit-lamp to raise the balsam of Canada to the point of ebullition, and then allow it to cool. In acting thus the tissue becomes discolored, while the bacteria remain colored.

This operation of ebullition is repeated two or three times, until the bacteria appear of a beautiful blue on a ground nearly colorless. These bacteria, thus colored, are from 1.5 to 2 millimetres long, and 0.7 of a millimetre broad. Each bacterium appears to be formed by several round or oval granulations united together in chains. In some few cases they appear to be uniform, and to be formed of one single piece. They are found in very great numbers in the medulla oblongata. They are also numerous in the spinal marrow, but more rare in the cerebral hemispheres; they are also found in the epithelium of the parotid glands. They are rare in the spleen and in the kidneys, but numerous in the liver, where they lodge in the interior of the hepatic cells. Professor Rivolta mixed the half of the medulla oblongata of a rabic rabbit with distilled water which was previously sterilized, and he then filtered the whole through a filter of porcelain. With the liquid thus obtained he inoculated three rabbits after having trephined them. At the same time, and by the same procedure, he inoculated two other rabbits with the liquid remaining on the filter. These latter animals died of rabies at the end of thirteen days, whereas the three first did not manifest any rabic symptom four months after the inoculation.

At a recent meeting of the Academy of Sciences, Professor Brown-Séquard was elected member in the Section of Medicine and Surgery in the room of Professor Vulpian, appointed Perpetual Secretary.

At the last meeting of the Academy of Medicine, Sir James Paget, the eminent English surgeon, was elected member in the Section of Foreign Associates.

Mademoiselle Ribard, Doctor of Medicine of the Faculty of Paris, who accompanied Paul Bert to Tonquin, died of dysentery soon after her arrival in that country.

THE TREATMENT OF FEVER BY COLD BATHS, ACCORDING TO THE PROPHET.—It seems that cold bathing for the reduction of high temperature is not a novelty by any means. Dr. Bertherand, writing in the *Gazette Médicale de l'Algérie*, translates portions of an Arabic work which prove that Mohammed was an advocate of this therapeutic measure. Asma, in a visit to a friend, found her sick with a fever and poured water over her, saying: "The prophet of God has commanded this, for the fever must be cooled as it is a fire from hell." When the prophet himself had a fever he had himself sprinkled with cool water three nights, just before the dawn, for he said that fever was "a whiff from the winds of hell, and must be overcome by means of cool water." The writer of the work gives directions for cooling the water still further, if necessary, by the admixture of ice or snow, and he says also, that it is sometimes of advantage to add vinegar to it.

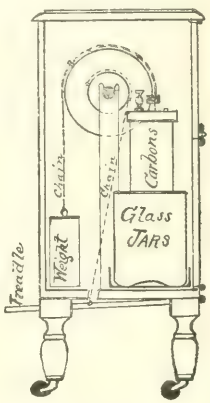
"THE SKUNK" is the title of a very strong article recently read before the Medical Association of Alabama.

New Instruments.

AN IMPROVED FORM OF GALVANO-CAUTERY BATTERY WITH DIFFERENT FORMS OF POINTS.[1]

BY BEVERLEY ROBINSON, M.D.,
NEW YORK.

To all specialists and workers in the field of nasal and throat diseases the galvano-cautery battery is at times an invaluable instrument. Hitherto it has not been used as often as it is desirable on account of the trouble of filling and emptying the cells, and the risk of spilling the fluid upon some article of value.



This statement is especially true of minor operations, or those in which some other means would answer fairly well. In making use of the improved form of galvano-cautery battery the objections urged above are reduced almost to a minimum. Besides, the battery can be kept in the office ready for any occasion when it is required. The fluid will rarely need changing, and when it is necessary, may be done with little annoyance.

I have been using one of these batteries during the past two months, and have found it a great convenience in office work. It seems to me equally well adapted to hospital work. Its cost is moderate, being $35.

As compared with a good storage battery with gravity cells it is two-thirds less expensive, and, I am inclined to believe, for cautery work alone will be found nearly as satisfactory.

In connection with the battery I desire to show you a number of cautery points and cups that I have found very serviceable in the treatment of different forms of nasal catarrh and hypertrophy of the turbinated bodies.

The following is the description of the battery given me by the manufacturer, Mr. H. E. Stammers:

"The cabinet galvano-cautery battery consists of a case of polished walnut 13×15 inches, 31 inches high, outside measurement. The top of the case opens on hinges. A door is placed in the back, as shown in the drawing, and two trays for holding the cords and electrodes, are set in the upper portion of the case. Two glass cells, 6×8 inches, are placed in a lead tray; three carbon and two zinc plates, 4×6 inches, are in each cell, connected with a counter balance weight by means of a chain which passes over a grooved wheel. Another chain is connected with a smaller wheel on the same shaft, and is attached to a treadle which, by depressing with the foot, lowers the elements into the fluid to any required depth.

[1] Shown to the Academy of the Practitioners' Society at a Stated Meeting held March 8, 1886.

A loop rate-rest holds the treadle in any suitable position, thus regulating the strength of the current to various sizes of electrodes. When the loop rate-rest is released the weight lifts the elements from the fluid and holds them suspended, ready for instant use. The ordinary bi-chromate of potash battery fluid is used (half a pint in each cell). One ounce of bi-sulphate of mercury should be added to each half-gallon of fluid after it is put in the cells, as it serves to keep the zincs amalgamated, and prevents a brown deposit from forming on them. If the fluid is in use several months, plain water may be occasionally added to it, to replace what is lost by evaporation. No corrosive fumes, however, rise from the fluid, unless a quantity of the solution is allowed to evaporate rapidly. The battery being provided with castors and handles, can be rolled, or lifted about, readily, and as the cells are only half filled, there is little danger of the fluid slopping over. The parts of the battery are constructed so that they can be taken apart and replaced in a few moments. The length of time the fluid lasts depends on the size of the electrodes employed and the length of time they are in use. For ordinary electrodes, when they are used about five minutes at a time, the fluid should last during twelve operations; one minute at a time, sixty operations—or what is equal about to one hour's work. For small electrodes the fluid should last during five or six hours' work, the explanation of this great difference in time being that a light *current* will still heat a small electrode even though it fails to heat a large one. Besides, the elements need not be lowered so deep into the fluid to heat the small electrodes. The treadle may be used as an *agitator* of the fluid whenever the current becomes too feeble to heat the electrodes properly, and will often serve as a valuable adjunct for this purpose."

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 4 to July 10, 1886.

PAGE, CHARLES, Lieutenant-Colonel and Surgeon. Leave of absence further extended one month. S. O. 156, A. G. O., July 8, 1886.

WATERS, WILLIAM E., Major and Surgeon. Ordered for duty as Post-Surgeon, Fort Spokane, Washington Territory. S. O. 112, Department of Colorado, July 2, 1886.

HOW TURKISH WOMEN PREVENT CONCEPTION.—One would suppose that the offspring at the harem would be large with such facilities at command, but such is not the case, the main reason being the systematic prevention of conception; and when pregnancy has occurred abortions are produced, of course not in every case, but in such cases as the master of the harem directs. Turkish women generally incline largely to these practices; consequently, the citizens of the empire are not increasing as they would under other conditions and circumstances. For preventing conception they use a piece of "bitter wood" an inch in diameter and about eight inches long. After the completion of the sexual act they proceed with this cylinder of wood introduced into the cavity of the vagina to mutilate the parts until free hemorrhage occurs, when they consider themselves safe.—Constantinople Cor. *Iowa Medical Reporter.*

MORALITY OF TURKISH WOMEN.—The Turkish women are, as a rule, true to the Turk. There is not a house of prostitution conducted by Mahometans in Constantinople. The English and other European representatives supply these immoral accommodations.—Constantinople Cor. *Iowa Medical Reporter.*

Medical Items.

CONTAGIOUS DISEASES IN THE CITY OF NEW YORK.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 10, 1886:

Week Ending	Typhus Fever	Typhoid Fever	Scarlet Fever	Cerebro-Spinal Meningitis	Measles	Diphtheria	Small-pox	Yellow Fever
Cases.								
July 3, 1886	0	7	25	3	7	63	2	0
Deaths.								
July 10, 1886	2	5	5	2	40	0	0	

THE TONGUE IN DISEASE.—A white-coated tongue indicates febrile disturbance. A brown, moist tongue indicates disordered digestion or over-loaded primæ viæ. A brown, dry tongue indicates depressed vitality, as in typhoid conditions and blood-poisoning. A red, moist tongue indicates debility, as from exhausting discharges. A red, dry tongue indicates pyrexia, or any inflammatory fever. A "strawberry" tongue, with prominent papillæ, indicates scarlet fever or rötheln.—*Technics*, March 25, 1886.

THE MICROBE OF SYPHILIS.—It is said (*La Enciclopedia*) that Alvarez has found a micro-organism in the normal secretion of the external genitals which is apparently identical, in form and characteristics, with Lustgarten's bacillus, supposed by him to be the specific microbe of syphilis.

THE DISCOVERER OF COCAINE.—Signor Torretti, professor of chemistry and pharmacology in the University of La Paz, Bolivia, has written a letter to the journal *El Ferro Carril* of Santiago, in which he maintains that cocaine was isolated for the first time in 1857, in the laboratory of the Botica y Drogueria Boliviana, by Sr. Pizzi, following the suggestion of the Austrian traveller Tschudy. He says that the manuscripts of Pizzi remain to attest the fact, and Herr Tschudy and Dr. Aquiles Reid, of Valparaiso, are still living and can add their testimony to support this claim.

OVARIOTOMY IN BARCELONA.—Dr. Miguel A. Fargas has published the histories of the first series of ten ovariotomies performed by him in Barcelona during the three years preceding July, 1885. The operations were performed as far as possible under antiseptic precautions. The first nine patients recovered, but death resulted in the tenth instance.

DETROIT INVECTIVE. — "Infinitesimal shrew-mouse squeaklet of a mediker," is one Detroit physician's characterization of another in the public prints. The language is unique and vigorous. We have endeavored to picture an individual to which it would literally apply, but having completely failed, conclude that it is merely a sort of figurative expression, calculated to convey the impression that the party of the first part cherishes none of that love for the party of the second part which the Scriptures enjoin.—*Medical Age.*

DEATH FROM DENTAL CARIES.—Dr. Poncet reports the case of a man who had an extensive gingivitis following caries of the teeth. He was admitted to hospital presenting the symptoms of septic poisoning, and died at the end of a few hours. At the autopsy numerous small abscesses were found in the mastoid process, and there were other evidences of septicæmia present. The origin of the disease was referred to the carious process existing in the teeth.

A Sign of Death.—Dr. Lesueur, of Amiens, says that one can determine with certainty whether a person is dead or not by thrusting a pin into the skin. In a cadaver the hole made by the pin will remain patent, just as if the pin had been stuck into a piece of leather, but if the person be alive the hole will immediately close, leaving scarcely a sign to show where the pin had entered the skin.

The Persian Mode of Treating Hernia.—Dr. J. P. Cochran sends to the *Medical Press of Western New York*, a description of the Persian radical cure for hernia. Dr. C. has seen three men who were perfectly cured. The method is described as follows: "We will take for example an oblique inguinal hernia. The intestine being reduced, the borders of the external abdominal ring are traced with ink, as a guide in the application of the hot iron. A thick ring of dough and somewhat larger in diameter is then placed around the part to be cauterized, to protect the adjacent tissues. The instrument used consists of a rough iron ring, one-fourth of an inch in breadth, and sufficiently large in diameter to include about one-eighth of an inch of the borders of the abdominal ring. It has an upright piece surrounded by wood for the handle; or it may be a solid disk, or else a ring with cross-pins in it. The patient is now made 'dead drunk' with arrack; or else, and especially if it be a child, is held perfectly still by a number of strong assistants. The iron is brought to a dull-red heat, and with all the neighbors—men, women, and children—who can crowd into the room where the struggling patient lies on the floor, the operation begins. The surgeon holds the instrument an inch above or over the part and as the surface is scorched and the iron has cooled somewhat it is placed within the ring of dough and directly upon the breach in the abdominal walls. After it ceases to burn the flesh it is again heated and the operation is repeated. The after-treatment consists in healing the ugly burn gradually."

Are We Still so Dirty?—Dr. George C. Wellner, of Wabash, Minn., writes: "I beg you kindly to permit me a few words of reply to your editorial, 'A Warning to the Careless,' of the issue of May 1st. You say: 'The medical profession, or rather the community at large, has cause to congratulate itself that it is living under the new dispensation of the gospel of cleanliness, and not dying from poison unconsciously administered by a careless or dirty medical attendant!' I believe your assumption is premature. We may indeed assert and reassert the gospel of cleanliness, but it is as yet idle to regard the community at large as living under the new dispensation, whether of Listerism or simple surgical cleanliness. The truth is, that a large proportion of the community at large dies now, as formerly, from poison, with this difference—that it is now *consciously* administered by a careless or dirty attendant. I say consciously administered, for since the advent of Listerism the medical profession has been well-nigh rationalized to death with the one or the other, Listerism or cleanliness, and it certainly cannot be possible that the efficacy of soap and water, as applied for the purposes of surgical cleanliness, must needs yet be persistently lauded and demonstrated to any number of the profession in America. We have now quite as much light already as we can manage well, and what we pray for now is more disposition to apply the facts we have. I mean that having embraced the gospel of either Listerism or cleanliness, the medical profession at large can have no excuse for withholding its dispensation. But, as yet, the great bulk of cases in which one or the other method is applicable, as well as most of the instruments in daily use, including the hands, do not receive even the odor of carbolic acid or the touch of soap. For example, the clinical thermometer is commonly removed from the patient's mouth to its case *uncleansed*. And it is fact, not fiction, that the pocket-case instruments—eye, ear, mouth, and nasal specula, tongue-depressor, catheters, and, indeed, the entire armamentary of minor instruments—are commonly not surgically cleansed. I do not wish to be understood as denying the existence of the new dispensation of the gospel of cleanliness. There is, indeed, a new dispensation, but it is, with a few exceptions, altogether quite within that comparatively narrow sphere of surgery and medical practice in which rivalry and emulation prevail. Without this sphere I believe we still partake largely of the old dispensation."

The Frequency of Rabies in Paris.—In 1885, there were 518 rabid animals killed in Paris and the Department of the Seine. Nineteen persons died of rabies.

Mineral Waters and Their Uses.—In an excellent article upon this subject, by Dr. Titus Munson Coan, in *The Journal of Reconstructives*, the following concise statements are given regarding the properties of the various mineral waters: For anæmia the reconstructive and tonic waters are needed, in conjunction with such diet as will restore the lacking elements of the blood. Beef peptonoids for the anæmia of dyspepsia; gluten bread and whole wheat bread for that of diabetes; cod-liver oil and milk for that of the phthisical diathesis are indicated. The springs of Auvergne, and of Salins, Luxeuil, and Bussang in France; Franzenbad in Austria, and our own Columbian Spring at Saratoga, will bring relief or cure when used with these adjuvants. When chlorosis accompanies constitutional anæmia, the contrasted influences of Alpine resorts and sea-bathing are alike useful. For asthma and bronchitis: Mont-Dore, Royat, Ems, Aix-les-Bains, Virginia Red Sulphur Springs. For post-nasal catarrh: Aix, Mont-Dore; but energetic local treatment in addition is sometimes needed. For dysentery: Rockbridge Alum Springs, Bussang in the Vosges. For dysmenorrhœa: the saline, iron, and sulphur springs must be chosen among. For dyspepsia: Carlsbad, Vichy, Pougues, Bagnères de Bigorre, Kissingen, Hombourg, Salins, Hathorn Springs, Greenbrier White Sulphur, and many others, according to the symptoms. For gout: Vichy, Vals, Royat, Buffalo Lithia, Sharon Springs. For acid gravel, the most frequent form: Carlsbad, Ems, Neuenahr, Buffalo Lithia, Capon Springs, Gettysburg "Catalysine." For alkaline gravel: the calcic waters. Clysmic is one of the best, and it is also a very pleasant table water. For hysteria: Pyrmont, Schwalbach, Spa, Néris, Schooley's Mountain, Rawley Springs, Congress Spring. A patient of mine, a delicate woman, found great relief at Luxeuil, in Eastern France. For intermittent fever and malaria, the waters of the Massanetta Spring have a desirable reputation. For laryngitis or "clergyman's sore throat," choose among the sulphur waters rich in sodium, or the alkaline, with chloride of sodium. Eaux Bonnes, Ems, Obersazbrunnen, Neuenahr, Selters, Sharon Springs, are typical and excellent waters of these kinds. For engorged and fatty liver: Carlsbad, Marienbad, Tarasp; when nutrition is badly impaired, Kissingen, Hombourg, Salins. For articular rheumatism: Aix, Springs of the Pyrenees, Hercules Baths, Baden Baden, Wiesbaden, Ischl, Sharon, Richfield Springs. For muscular rheumatism: thermal springs, as Teplitz, Warmbrunnen, Gastein, Ragatz, Plombières, Lebanon Springs. For torpid scrofula: Salins, Kreuznach, Ischl, Kosen, Bourbonne-les-Bains, Rockbridge Alum, Greenbrier Springs. For irritable or "erethic" scrofula: La Bourboule, St. Nectaire, and other springs of Auvergne. For skin diseases: the sulphur and arsenical springs offer a vast field of choice, according to the character of the case. Uterine diseases are variously treated by the alkaline, muriated, or saline waters, and with brine baths or the ascending douche. They form a large contingent of the cases treated at mineral springs, both here and abroad.

THE IMPORTANCE OF AN EARLY DIAGNOSIS IN CASES OF GENERAL PARESIS.[1]

BY HALSEY J. WOOD, A.M., M.D.,

[illegible]

Not many months since, there died in a neighboring city a distinguished actor, for years unapproached in the delineation of robust tragedy; upon whose lips thousands hung in admiration, and yielded their emotional nature to the sway of his own. A giant in his art, he toppled over, a mental and bodily wreck, at an age that should have witnessed the maturest expression of ripened genius.

But before he died—before, indeed, he had left that stage upon which his latest efforts all too surely presaged "the mighty tree thundering to its fall," he was permitted for weeks to keep up the melancholy travesty of his former genius; to riot in the excesses and indulge the extravagances peculiar to his disease, and to be permitted that liberty he could no longer govern, until he had reduced a noble physique to helpless decay; an exalted mind to empty fatuity; a considerable fortune to absolute penury; his wife and children to future charity.

A few days ago, there was admitted to Bloomingdale Asylum a prominent and successful dramatist, in the early stages of a progressively fatal disease. Early, but not in time to save from the wreck of a once sufficient competence the large sums squandered in the expansive and chimerical schemes bred by a diseased intelligence. His wife and family are in poverty, and he must be supported for the brief span left him by the benevolence of his former professional associates.

These are by no means rare cases. Similar ones might be multiplied by tens and by scores. The comfort and support of hundreds of wives and mothers, the accumulations of years, the studied economies of a lifetime, have been squandered in weeks in the delusional mania of which we speak.

My apology for the introduction of this subject before the Society is the comparative infrequence of such cases in the experience of the general practitioner, the importance of their early recognition, and the disastrous consequences of delay. It has been my fortune, in an asylum experience of more than seven years, to see many cases of general paresis. These were admitted in various stages of the disease, and in but three instances was the condition of the patient recognized prior to admission. This, I am well aware, indicates an extreme state of things, and argues an unfamiliarity with the subject only possible at a distance from medical centres. To see a sufficient number of cases to thoroughly familiarize one with the morbid manifestations, is sufficient, in most instances, to render the diagnosis prompt and certain.

To the French physicians belongs the credit of the earliest recognition of the disease, attention having been called to it in 1822 by Bayle. The first complete account was, however, given by Calmeil in 1826, and to him is frequently ascribed the merit of having been its discoverer.

[1] Read before the Harlem Medical Association, [illegible]

Many names have been proposed for it. Of these the most important are: General paralysis of the insane, paralytic insanity, paralytic dementia, incomplete general paralysis, progressive general paralysis, and general paresis, or simply paresis. It is proper to protest, in this connection, against the use of the terms paralytic insanity, or paralytic dementia, to indicate this disease, as they are properly associated with the organic dementia resulting from gross cerebral lesions, as apoplexies, ramollissements, tumors, atrophies, and chronic degenerations of the brain, affecting the convolutions and their functions, either primarily or secondarily. They have nothing whatever to do with general paresis, their use only confuses the issue.

Of late the term general paresis has been commonly used, and although it may be urged that, in preferring it to general paralysis, we substitute for the old name one equally vague and unscientific, the custom, if not the wisdom, of modern times is in the usage, and we shall follow it in our subsequent reference to the disease.

General paresis is a distinct disease, physiologically, pathologically, and psychologically; as unique and separate from all other disease as is variola from scariatina. I quote the following very satisfactory definition of general paresis from Dr. Clouston's "Clinical Lectures on Mental Disease":

"A disease of the cortical part of the brain, characterized by progression, by the combined presence of mental and motor symptoms; the former always including mental enfeeblement and mental facility, and often delusions of grandeur, and ideas of morbid expansion or self-satisfaction; the motor deficiencies always including a peculiar, defective articulation of words, and always passing through the stages of fibrillar convulsion, inco-ordination, paresis, and paralysis; the diseased process spreading to the whole of the nervous tissues of the body; being as yet incurable and fatal in a few years."

The victims of this disease are, for the most part, robust, middle-aged, active-minded men. It steadily progresses and rapidly destroys all that is human in the unfortunate subject, leaving him to exist for months together "an unconscious automaton."

It may be well to consider here the question often asked, whether general paresis can exist without mental disorder. Dr. G. H. Savage, editor of the *British Journal of Mental Science*, in his recent work on insanity and allied neuroses, asserts that he has seen several such cases in the wards of general hospitals; cases presenting all the physical symptoms, and to this extent undistinguishable. Griesinger, however, strongly dissents from this position, asserting that the cases are not similar, that they do not ultimately manifest the purely mental symptoms. Indeed, Dr. Savage acknowledges this issue to have occurred in very many of the cases referred to, the disease rapidly progressing to a fatal termination. A general impression as to the causation of general paresis, is that it depends upon *sexual excess*. Dr. Maudsley supports this view. Dr. Blandford writes: "I have held for some years the opinion, based altogether upon my observation of cases, that sexual excess has more to do with the causation of it than anything else." But the growing testimony of observers is in the direction of less positive assertion. The increasing number of cases in which this factor cannot reasonably be adduced as present, or as an important cause, demands a more guarded utterance. Undoubtedly sexual excess has much to do

with the causation of the disease, as does great alcoholic indulgence and other toxic influences; but it is chiefly in combination with other depressing and degenerating agencies that its force is recognized. It should be borne in mind that sexual excess is a common early symptom of the disease, and the effect should not be mistaken for the cause. The fact is, it is very difficult to establish the existence of sexual excess. Apart from the uncertain and unwilling testimony likely to be furnished, individuals differ greatly in susceptibility to the action of such a cause; excess for one being moderation for another. Syphilis is an active and undoubted cause in many cases, the extensive chronic degenerations peculiar to its course greatly predisposing to attack. But the cause or factor *most* commonly present, according to the experience of modern observers, is that of *anxiety, over-strain*, rather than overwork. The exhaustion consequent upon a prolonged struggle in the battle of life, with the odds always against one; the exhaustion, too, that comes to the successful toiler—successful in grasping the prize after a life of arduous struggle, to fall by the wayside a wreck! "Excessive mental excitement, and, in a still greater degree, emotional agitation," writes Griesinger, "appear to be important factors in its production" ("Mental Diseases," p. 401). Anxiety about business, sleeplessness, worry, loss of appetite, prepare the way for the sexual and alcoholic excesses that too often step in and give the finishing stroke.

"To sum up: general paresis arises, as a rule, from a combination of causes; the most direct being excesses of all kinds, whether sexual or alcoholic, which act more powerfully when associated with strain, worry, and anxiety. Traumatism affects some, as may also such diseases as syphilis," writes Dr. Savage.

General paresis is usually divided into three stages. Like everything else, it has a beginning and an end, and there is, of course, an intermediate period of varying duration. Roughly speaking, a period of incubation, a period of excitement, and a period of dementia. Blandford divides them into: 1, alteration; 2, alienation; 3, progressive paralysis and dementia. These are, however, quite inexact. Dr. Clouston classifies as follows: "The first stage is that of fibrillar tremblings and slight inco-ordination of the muscles of speech and facial expression, and of mental exaltation with excitement; the second, that of muscular inco-ordination and paresis with mental enfeeblement; and the third, that of advanced paresis, or no power of progression, almost inarticulate speech, and at last paralysis, with mental extinction" ("Mental Diseases," 1883, p. 354).

The first thing noticed by the friends of a general paretic is that an *alteration* has taken place in him. Before it is manifest that he has become insane, a change in habit or manner of life will be sure to attract attention. The nature and amount of this change will vary with the business, social position, education, etc., of the individual, but it will be noticeable as contradicting his previous character and habits. And it is an interesting fact that, in this progressive degeneration, it is the last and highest acquirements that fail first, so that the musician loses his power over his fingers, the seamstress can no longer sew, the *danseuse* forgets her steps, and the actor his part. The prudent man becomes suddenly prodigal; the cautious man, reckless; the modest, boastful; and the refined, coarse and obscene. And there will be an extravagance and silliness in all that is done that argues a peculiar want and mental defect. In the delusions of acute mania there is a certain reason in the unreason; for the acutely maniacal patient will often throw a certain air of probability about his claim by his urgent defence. But the general paretic does not argue about his delusions, and is rarely disturbed by contradiction. He advances rapidly from one notion to another, forgetting the one that dominated him yesterday in the brilliance of the one conceived to-day. Loss of memory for recent occurrences is a very noticeable symptom at this time, and is so marked as to explain much that he does or fails to do. He forgets appointments, payments, obligations. His notes go to protest, his business is in confusion from his lack of coherence and system. He gives opposing orders to his servants, and flies into a rage if they are not instantly executed. The purchase of useless articles, the sending of numerous letters and telegrams, and the accumulation of worthless trash are common symptoms. A patient of mine had expended $1,500 in the purchase of a barnful of wagon-jacks before his insanity was discovered. He is often destructive at this stage, tearing garments, books, etc., in shreds with the idea of an improved reconstruction. A general paretic alluded to by Clouston, tore his overcoat into strips, laying them upon the floor side by side. When remonstrated with, he replied, "I'll p-put it tog-g-ger ag-gain when I g-get to Jerush-lem—I've g-got a million coats there." His sleep is apt to be broken at this time. Some patients are so possessed by active delusions that they forget to go to bed. The appetite for food is often voracious, and the patient drinks excessively, forgetful of what he has already taken. But, in connection with these mental symptoms, there will also be observed peculiar motor disturbances. While the patient is giving utterance to his exalted delusions a defect in articulation, a slurring, slovenly enunciation is commonly noticed that is very characteristic. It suggests the speech of a man suffering from alcoholic intoxication, and these cases are not infrequently mistaken for such at this stage. Dr. Connolly describes it well in this wise: "There is in these patients, not a stammer; no letter or syllable is repeated, but a slight delay; a lingering, a quivering in the formation of the successive words or syllables, apparently from the want of a prompt nervous influence in the lips and tongue." In addition to the tremulousness and quivering of the lips, which at a later date extends in many cases to the facial muscles, there is a fibrillar tremor of the muscles of the tongue. The patient has little control over this organ. When asked to protrude it, a perceptible delay occurs before accommodation enables him to obey. The tongue is then shot forth convulsively, while it shivers, darting back and forth. Upon its surface are seen the fibrillar contractions of separate strands of muscle, quivering in well-defined lines. Irregularity of the pupils is a symptom present in a large proportion of cases. It is often transient, and may be present in the different stages throughout the disease. It is rarely permanent. Atrophy of the optic disks is a frequent symptom, but commonly occurs later. The first stage may last for several weeks. In the commencement of the second stage, the patient is often sulky, dull, and apathetic for a time, but exposed to attacks of sudden and violent excitement that commonly render his seclusion in an asylum a pressing necessity. To this condition there rapidly succeeds a mental exaltation, so characteristic as to be almost pathognomonic. Exalted delusions are common to several forms of mental alienation, but there is a preposterous absurdity about the claims of the general paretic that distinguishes them. Individuals suffering from acute mania, chronic mania, and monomania, will often claim to be kings and queens, but the general paretic will assert that he is God, the president, king, emperor, czar, duke, and marquis all at once, and if you suggest to his receptive mind other regal and princely titles, he will promptly appropriate them.

In addition to all this he has billions of millions of dollars, is to be married to-morrow, at Windsor Castle, to the Queen of England, who is to be but one of his hundred thousand wives, and that he has ordered all the steamboats and rail-cars in the world, his personal property, to transport spectators to the ceremony. A patient under my observation, seriously announced to me that he owned a reef of solid gold one hundred miles square, twenty leagues south of the Cape of Good Hope; that a million vessels manned by a billion men were, under his orders, engaged in removing this precious treasure and

carrying it to America, to be stored in his millions of billions of storehouses. He could, Midas-like, make gold by touching any baser thing, but, unlike Midas, could restrain the action of this talent at will. He was the strongest man in the world, had whipped all the noted pugilists, and could lift a ton of coal with his little finger. After the utterance of these boasts, it was by no means uncommon for him to beg a "chew of tobacco," and after describing how completely he had "laid out" John L. Sullivan, to ask assistance in reaching another part of the hall. General paretics accept and implicitly believe, as a rule, the delusions uttered by their fellow-patients. This is at variance with other forms of mental disease, for the contrary is generally true. Exceptions occur, however. Dr. Savage quotes the following conversation between two general paretics. "I am king of England," said one; the other, turning with a scornful laugh to me, said, "That man says he is king of England; I am God Almighty, and I don't know him." In the same way I have known a medical paretic recognize the disease in others by the very symptoms from which he was himself suffering. Anæsthesia of special senses is sometimes marked in this stage, and is usually more or less present. The ability to smell pepper is at times, though rarely, absent. The inability to taste quinine in solution is common. Color-blindness is frequent.

These patients are facile, easily diverted from their delusions, and usually conform to necessary restrictions without objection.

All paretics do not have these extravagant delusions, a sensible percentage being depressed and melancholic through the expansive period of the disease. This change often seems due to the presence of some visceral lesion, the cure of which is followed by the ordinary mental symptoms. But these cases are never melancholic, as are cases of melancholia. They usually eat well, and their depression, albeit accompanied by a dull and lethargic mental action, often gives evidence of a good deal of self-feeling. Such patients are often vain of their personal appearance, and evince ideas of self-importance in a more or less subdued form. In the third stage these cases differ in no respect from those previously described.

In the second stage the motor symptoms are more marked, and keep pace with the mental. The tongue-tremor and defective speech increase. The patient cannot say "Round about the rugged rocks the ragged rascals ran" without a serious clipping of syllables. A slow, shuffling, cautious gait, not at all like the walk of the hemiplegic or tabetic, is commonly seen at this time. It is hurried, spasmodic, like a man starting off for a run. They go ahead pretty well, but if suddenly called upon to stop, they cannot accommodate rapidly, and so come about clumsily, in a considerable half-circle. Alteration in penmanship is a very early symptom, the handwriting becoming coarse, illiterate and tremulous from increasing muscular inco-ordination. There is a strong and increasing tendency to drop words, the shorter and least important being usually omitted through forgetfulness. Epileptiform and congestive attacks are certain to occur more or less frequently throughout the disease. These are followed by hemipareses or paralysis of a more or less extended character. There is usually a subsequent period of confusion, that in some cases becomes unconsciousness, following these attacks, and is of variable duration. But any hemiplegia is soon recovered from, thus distinguishing these fits from apoplexy. Marked mental deterioration follows these seizures, patients often becoming careless of their person and gross in their appetites. The fits may kill at once, or may recur at irregular intervals, following a similar course in each attack. Hæmatoma auris is a frequent sympton in general paresis, may be unilateral or bilateral, and consists of a bloody gelatinous effusion separating the outer skin from the perichondrium. If left alone the tumor swells, fills the cavity of the helix, and at times ruptures. But whether it ruptures or shrivels, there is usually, unless properly treated, great resultant contraction and deformity. Alteration in the tendon reflexes should be mentioned as present in a large proportion of the cases. These may be abnormally exaggerated or diminished; in a few instances they appear unaffected. The patellar tendon reflex is the one most commonly examined. Patients are very prone at this time to become emotional; breaking down in the midst of a statement of some extravagant claim to weep piteously. Hysterical laughter is frequent also. Both appear without appreciable cause. There is a slight evening rise in the temperature of the general paretic. This is seldom less than 1°, save in cases where the disease is arrested; then it may be as little as 0.4°. Bucknill and Tuke give the temperature record of a case under observation from August, 1869, to January, 1875, in which the above fact is clearly demonstrated. Of course all diseased action which gives rise to increased temperature, independently of disease of the nervous system, must be carefully excluded. Dr. Macdonald, of the New York City Asylum, in an article published in the *American Journal of Insanity*, April, 1877, states that, in his cases, the average of difference between the morning and evening temperature was half a degree in *sthenic* cases, while in the asthenic form it was *lower* by half a degree in the evening than in the morning. He adds, fifty cases give a rise of 1° between temperature before and after a maniacal exacerbation, and of 1½° between that before and after a convulsion.

In the latter part of the second stage, as his mental movements become dull, the loquacity of the paretic subsides and his delusions are infrequently referred to. He accumulates flesh, becomes fat and gross, and his skin is flabby and greasy. Considerable mental improvement sometimes accompanies this remission, and patients are often removed from asylums by their friends in the belief that they are recovered or much improved. This hope is, however, fallacious. If removed they rapidly relapse. They are incapable of effort or continued application, and deficient in memory. The attempt causes exhaustion and lights anew the acute symptoms that had been allayed. At times, however, the apparent improvement, under favorable circumstances, may continue for a year or more. At such times it is not uncommon for the friends of such an one to move to set aside the action of the court in the appointment of a guardian over the person and property of the patient. Medical testimony is often sought as to the competency of patient to manage his business interests. It is never wise to set aside such control, a delay of a few weeks or months being usually sufficient to dissipate the favorable symptoms. This change is indicated in fresh excitement, degraded habits, and rapid mental and bodily degeneration. The facial expression becomes vacant and puffy. He rapidly tires; can walk but little, and requires constant attention. If confined to bed, bed-sores appear and rapidly spread. Complete relaxation of sphincters and the filthiest habits are common. His speech is now a tremulous drawl. He occupies one position for hours, hopelessly demented, and utterly fatuous. Discordant grinding of the teeth is a very common symptom in this stage; this is often kept up until the teeth are worn to the gums or are loosened from their sockets and fall out. The appetite is still good, but deglutition is apt to be feeble. If not carefully watched, patients will go on filling their mouths with food until it is impacted in œsophagus or larynx and strangulation is imminent. Many die in this way. The patient now requires the care and attention of a young infant, and as he gradually sinks into mental extinction, you may often catch in his eye the ecstatic self-absorption his tongue can no longer voice.

That ends this strange, eventful history,
[illegible]
[illegible]

Authorities agree in giving the average duration of general paresis as three years. Cases do, however, last longer, a duration of six years being not very uncommon. Blandford had a case that lived fifteen years, and Clouston one that had lasted *twenty-three* years at time of writing (1883). This phenomenal duration would seem to throw doubt upon the diagnosis. Males are largely the subject of general paresis, suffering eight times more frequently than females. Dr. Savage notes an interesting fact in this connection, that, with the enlarging scope of woman's work, cases of this disease are with them much more frequent. It is most common between the ages of thirty-five and forty-five. It rarely occurs before twenty, although cases have been reported at a much earlier age. The prognosis is uniformly bad. There is no well-authenticated case of recovery from general paresis. I have not mentioned the peripheral, sensorial, and tabetic forms of the disease, as they differ from the cases described in inception alone, their subsequent history following the characteristic course. It is sufficient, perhaps, to intimate that cases may originate in this way.

"The diagnosis of general paresis," says Griesinger, "is, in the great majority of cases, no difficult task. It is based upon the symptoms we have been describing; the general and incomplete nature of the paralysis; its progressive nature; upon the convulsive character of the early symptoms of the disease—its commencement with trembling of the tongue and lips; upon the special character of the mental derangement, particularly the ideas of greatness and the rapidly ensuing mental weakness; upon the irregular course. It is by regarding these symptoms that we, in general, succeed in distinguishing this affection from paralysis due to cerebral hemorrhage, embolism, encephalitis, tumors of the brain, hysterical and toxic paralyses; from progressive spinal paralysis, the tremor of old age, and grogressive muscular atrophy." It should be added that the diagnosis between this disease and conditions present in the insanity of chronic alcoholism is often, in the absence of a history of the case, well-nigh impossible. Dr. B. B. Fox, an English alienist, in the *Journal of Mental Science* (July, 1884), after giving cases of chronic alcoholism, in which all the typical symptoms of general paresis were at times manifested, adds:

"The mental exaltation of chronic alcoholism in some cases possesses nothing to distinguish it from general paresis. Occasionally, too, the physical signs of the two diseases so far resemble one another that they can only be differentiated by the history and other circumstances connected with the case, and in some rare instances only by watching the course of the malady. The delusions of chronic alcoholism are usually fixed, constant, and ineradicable."

The temperature changes are also absent in chronic alcoholism. Cases of chronic maniacal excitement often present diagnostic difficulties—puzzles that can only be solved by a careful analysis of symptoms and opportunities for prolonged observation.

From what has been said it will be inferred that the treatment of general paresis is unsatisfactory in the extreme. To attempt the treatment of a disease recognized as incurable cannot fail to be so. Yet, symptoms can in many instances be ameliorated, and the person and property of its unfortunate subject be protected by early recognition of the nature of the disease. First of all, the paretic needs a complete change of surroundings, removal from home, absence of all cares and responsibilities, a non-stimulating diet, and suitable out-door exercise, which should be under observation and not exhausting. Excesses of any sort operate unfortunately. An increased susceptibility to the influence of powerful drugs is noticeable, and considerable caution in their administration is required. The perfection of careful nursing, under unstimulating surroundings, does more to prolong the life of the paretic than anything else. For these reasons the longevity of paretics whose circumstances admit of constant observation and careful individual attention is much greater than in ordinary cases. The *advantage* of this, however, in a disease so distressing in many of its phases, and so certainly fatal, may well be questioned.

The *pathology* of general paresis has little to do with its *early* diagnosis, and is, therefore, rather without the scope of this paper. Cases occur that cannot be, or, at least, are not recognized until the characteristic degenerations are found at the autopsy. To go fully into this department of the subject is beyond my purpose and the limits of this article. It will be sufficient to give a rapid *résumé* of the appearances commonly present. Changes are marked in proportion to the duration of the disease. The scalp is thick and hairy; the calvarium dense, thick, and hard; deploë often obliterated. The membranes are all thickened and toughened, and commonly are abnormally vascular. The dura, in addition, is more or less adherent, and is separated from bone with difficulty. The arachnoid is mottled with white spots, or striated with white bands along the sulci. The convolutions are seen dimly beneath this through an opaque, gelatinous fluid that oozes out when the arachnoid is pricked. This is a compensatory fluid that fills the subarachnoid space, taking up the room lost through atrophy of the convolutions. The pia adheres so closely to the outer layer of gray substance on the *ridges* of the convolutions that in attempting to raise it portions of the cortex are pulled away with it, giving the convolutions an eroded appearance that is very characteristic. Considerable wasting of the gray matter is noticeable in cases of protracted duration. A line of red congestion is seen between the layers of gray matter, and irregular patches of congestion are found in the white substance. The ventricles are nearly always enlarged, and often contain an excess of fluid.

There are no constant visceral lesions. What, then, *is* general paresis?

Dr. Joseph Wigglesworth, in an article on the "Pathology of General Paralysis," published in the *Journal of Mental Science* (January, 1883), calls attention to the extensive hyperplasia of connective tissue, and increase and development of the cells of the neuroglia found in all cases of general paresis, as ground for the following deduction, as ingenious as it is fascinating:

"The conclusion, then, finally arrived at is, that general paresis is a true interstitial inflammation of the brain running a subacute or chronic course; that it is, in fact, a true cirrhosis of the brain altogether comparable to cirrhosis of other organs, such as that of the liver; in other words, that connective-tissue hyperplasia is the primary element in the disease, and the affection of the nerve-cells secondary."

This view was first advanced by Rokitansky, and other pathologists have given it their adherence.

57 West 130th Street.

The Surgery of the Pancreas.—In an elaborate paper, based upon experiments and clinical researches, and published in *The American Journal of the Medical Sciences* for July, 1886, Dr. Nicholas Senn attempts to lay the foundations for a rational method of direct surgical treatment of some of the injuries and diseases of the pancreas. The literature on the surgery of the pancreas is exceedingly scanty, and loosely scattered through the medical journals and text-books, as no previous attempt has been made to arrange the material in a systematic form for ready reference. Our present knowledge of the surgical treatment of diseases of the pancreas is limited to a few operations performed for the cure of retention cysts, by excision or the formation of an external pancreatic fistula. The clinical material which the writer has collected, and more particularly the description of pathological conditions found within and around the pancreas at post-mortem examinations, is utilized for the purpose of pointing out new indications for operative interference, by such methods as will suggest themselves from the results obtained by experiments upon animals.

THE DEATH-PENALTY: PROPER MODE OF ITS INFLICTION.

By WOOSTER BEACH, M.D.,

NEW YORK.

CAPITAL punishment under the laws of the United States may be inflicted for treason, murder, arson, rape, piracy, robbing of the mails, if associated with jeopardy to the lives of the custodians, rescue of a convict about to be executed, burning a vessel of war, and corruptly destroying a private vessel.

In Iowa, Wisconsin, and Maine capital punishment was abolished, but restored in the former State after four years' trial, as during this period it was found that there had been a material increase in violent crimes.

In former times death was the ordinary punishment for all felonies, and it is within the memory of some of our residents that persons were hung for robbery and other comparatively slight offences. Popular feeling tends at present toward the entire abolition of the death-penalty, but it is pretty generally conceded that the time for such a change has not yet arrived. All, however, seem to agree that when the death-penalty is inflicted it should be done skilfully, expeditiously, and in a manner causing the culprit as little pain as possible.

That with us this humane plan is frequently not carried out is attested by the numerous reports in the newspapers of bungling executions. In some the trap has failed to fall, and the prisoner has had to undergo the agony of a second and, in a recent case in England, a third preparation for death before the scaffold could be made to do its duty.

In others the same thing has occurred from the rope used for hanging, breaking as it was suddenly strained by the weight of the body. Again, the drop has been so long that the head has been completely torn from the trunk by the force of the fall.

At other times the noose has not tightened enough to completely cut off the air-supply, and a strangulation could only be effected by readjustment of the rope, while the body was still suspended. A mishap of this kind occurred when a negro was hanged at the city prison a few years ago. He was able to cry out for help for some time after being jerked into the air.

Various other accidents have happened, even when the hangmen employed have had experience and had the reputation of being skilled in their duty.

These painful exhibitions usually call forth expressions of horror and disgust from the press coupled with a tirade of censure against the "bungling hangman," and then the matter is dropped until, perhaps, the next execution, when there will be some variation in the bungling, and some variation in the press comments, but otherwise no change follows.

Attempts at reform in carrying out the death-penalty have been made in this country, but they have been mostly suggestions of some substitute for hanging.

On April 3, 1878, Dr. John H. Packard, of Philadelphia, read a paper before the Medico-Legal Society of this city in which he advocated the use of carbonic-acid gas to take the place of hanging. He proposed that a tight chamber, so arranged that it could be rapidly filled with the gas, be provided, and that the criminal, after being properly identified, be placed in it, the gas turned on, and he allowed to remain there until life was extinct.

Carbonic acid or carbonic oxide is used in a similar way to destroy dogs at the Philadelphia pound, and it works rapidly and effectually.

A committee was appointed by the Society to consider the paper of Dr. Packard. Their report was adverse to the proposed plan, or to any other than hanging.

In the discussion of the report Dr. William A. Hammond said that the proper method to hang a man was to dispense with the usual traps and weights, and draw up the body slowly. He further suggested that weights might be attached to the feet to obtain sufficient tightness of the noose to effect strangulation.

A paper was read before the Society of Medical Jurisprudence of this city by Dr. N. E. Brill, in which the inhumanity of the present mode of inflicting death was dwelt upon and a remedy called for. A committee on this subject was appointed who drew up a bill and presented it before the New York Legislature, but it was not passed. The bill made it possible for the culprit to choose the mode that should be used to take his life.

Dr. Graeme M. Hammond read a paper on hanging before the Medico-Legal Society in 1884, describing his own sensations when submitting to an experiment in which his neck was tightly constricted by a towel. From his experience and his study of the subject he reached the conclusion that death from hanging was not especially painful, and he advocated the plan, previously spoken of, of Dr. William A. Hammond, viz.: a slow, carefully conducted suspension of the body.

The methods of inflicting the death-penalty in civilized countries, other than by hanging, is, beheading by the sword in Germany, by the guillotine in France, garroting in Spain.

The substitutes for these, besides the one mentioned by carbonic-acid gas, are electricity, poisoning by hydrocyanic acid, or by chloroform.

The writer, in addition, would propose shooting, either as in military executions, when, if expert marksmen were employed as executioners, certain, speedy, and painless death could be relied upon; or, the following even more certain plan is suggested: Secure the condemned individual in such a position that a vital part shall be struck by a ball from the weapon which previously has been sighted and screwed fast in place. Thus any person discharging it could not fail to do so with fatal effect. The principal objection urged against electricity is that it is uncertain; that the apparatus for generating it may not be in perfect order; or, for other reasons, the charge may not be powerful enough to produce death. This objection can scarcely hold at present, as with improved machines a galvanic current quite powerful enough to kill a man can be generated with absolute certainty. Chloroform or hydrocyanic acid can be depended upon to cause speedy and probably painless death.

All these untried methods would undoubtedly be exceedingly difficult to bring into use to replace the present custom, firmly established by its employment for so long a time.

With shooting as a mode of execution, however, the public is familiar. It is adopted in the army, and it does not appear to the writer that it would be especially difficult to make its use general if it could be shown to possess special advantages over hanging.

But, before deciding on any attempt to substitute any other method for this, it will be well to examine its claims more fully.

Judicial hanging is now done in two ways. The person to be executed is either suddenly drawn up by a heavy weight or dropped by springing a trap on which he stands. In both cases there is more or less slack rope used, so that it is pulled taut with a jerk violent in proportion to the amount of slack and the weight of the body. The intention of the hangman is to cause death by breaking or dislocating the neck, rather than by strangulation. This failing, it is supposed that the jerk from the shock will be sufficient to abolish sensation to a degree that will prevent suffering from the constriction of the rope.

The rule is that none of these objects are accomplished by the methods in use.

Autopsies of bodies that have been thus hanged show that in not over five per cent. is either dislocation, fracture, or any injury to the cord observed. Unless the long drop is used, in which there is great danger of the head being torn from the body, it is unlikely that the vertebræ will be broken or displaced.

The movements of the individual soon after being suspended indicate purpose too plainly to be attributed to "reflex action," as is maintained by some, and if this does not prove that consciousness and sensibility are not destroyed by the fall, the fact of intelligent exclamations having been made under the same circumstances cannot make the matter doubtful.

It appears very certain, then, that neither the drop nor the weight accomplishes the wished-for object—a painless death—on the contrary, the effect of both is to very decidedly add to the suffering. The violent tightening of the noose not only deeply indents and wounds the surface of the neck, but the larynx or trachea are actually fractured by the powerful constriction, and until strangulation occurs, which is quite likely to be prolonged, from the rope being misplaced by the fall, the victim cannot but suffer exquisite torture till asphyxia produces insensibility.

In exceptional cases death from judicial hanging appears to be painless. The body remains motionless after it is suspended, and there is every indication showing that, with the tightening of the noose, immediate abolition of sensation takes place, yet examination after death shows no injury to brain or cord.

What is the explanation of these expeditious deaths? A study of the subject must lead to the conclusion that they will occur if the entrance of the air and its exit is completely prevented.

To discover the most effectual way of doing this, the writer made the following experiment: The thorax of the body of a man about thirty-five years of age was opened, the trachea divided low down, and a tube fastened into it. The neck was so arranged that a loop of rope crossed the throat, and, hanging down beneath, weights could be attached, thus indicating the pressure of the rope on the air passages. By blowing through the tube, the amount of obstruction to the passage of air could be appreciated with considerable exactness. It was found that fifteen pounds weight on the rope would produce complete obstruction if the pressure was brought to bear on the os hyoides, or just beneath over the thyrohyoidean membrane; but below, on the larynx or trachea, the weights that have been provided for the experiment were insufficient to stop the passage of air. The weight of a person (say one hundred and twenty-five pounds) standing on the loop, was not enough to produce occlusion.

That slight pressure, if properly applied, may cause death is attested by occasional suicidal cases. In one, observed by the writer, in this city, a large silk neckerchief served for the purpose of self-destruction. It was tied in a loop, one end of which suspended the neck of the suicide, and the other was thrown over the post of a low bedstead. Nearly the entire length of the body touched the floor, the head and chest only being held up by the neckerchief.

Similar cases are reported in works on medical jurisprudence. A number are described and illustrated by Tardieu, in "La Pendaison," all showing death to have resulted from very moderate pressure on the air-passages. Various causes of death in hanging are given, besides asphyxia. Shock, syncope, injury to the cord or medulla, obstruction of arterial and venous circulation, pressure on the vagi are said to take a more or less prominent part in extinguishing life. That the first three mentioned must act promptly cannot be denied, but they occur very seldom. Insensibility might take place after a time from pressure on the blood-vessels and nerves, but this cause could scarcely come into play in ordinary hanging.

Asphyxia, then, is what we have to depend upon to produce death, or, at least, the insensibility preceding death in our criminal executions.

That asphyxia can be produced with comparatively slight pain or distress when the constriction to the neck is made under certain conditions is proved in various ways.

Almost conclusive proof is furnished by the statements of those who have accidently been rendered unconscious by hanging and have been resuscitated—such as the cases of Fleischman and Hornshaw, quoted by Taylor, which certainly seem to prove the moderate amount of suffering caused by asphyxia. Dr. Hammond's experiments are also to the point.

It would seem, then, that if we wish to take life by hanging in the most speedy, certain, and painless manner we must adopt the plan before mentioned, as recommended by the Drs. Hammond—to put a rope around the neck of the man and slowly draw him up.

But this is not all that is required. It is essential that the noose be carefully placed, so that on tightening, it shall constrict the parts necessary to entirely cut off respiration; that is, just above the larynx, and there it shall remain unmoved till death takes place.

Some contrivance might easily be invented to hold the rope in place, as it is drawn taut, but the average sheriff ought to be depended upon to effectually manage so simple a matter.

OPHTHALMIA NEONATORUM—ITS CAUSE, PREVENTION, AND TREATMENT.

By J. E. WEEKS, M.D.,

NEW YORK,

RESIDENT ASSISTANT SURGEON OPHTHALMIC AND AURAL INSTITUTE, ETC.

It is not my intention in the following paper to discuss at length the cause and prevention of ophthalmia neonatorum. These points are already fairly well settled. As, however, there exists a wide diversity of opinion among the members of the medical profession in this country as to the proper method of treating this disease and gonorrhœal conjunctivitis in the adult, I may be pardoned for dwelling at some length on this point.

Ophthalmia neonatorum probably causes more blindness than any other one disease that the eye is subject to. An idea of the number of blind so caused may be obtained from the following: Institute for the Blind, London, twenty to thirty per cent. (Brady, 1884); of 326 blind in Constantinople, 4.3 per cent. (Milligan); Landesblindenanstalt, Purkeisdorf, sixteen per cent.; of 2,528 blind reported by Magnus,[1] 1883, 10.82 per cent.; of the blind in the city of Breslau,[2] 17.5 per cent.; in Mecklenburg,[3] of 172 cases of ophthalmia neonatorum, seven per cent. became blind; Horner states that of the children brought to the institutions for the blind in Germany and Austria, thirty-three per cent. have lost their eyes by this form of blennorrhœa. These figures are sufficient to indicate the importance of a thorough knowledge of how to prevent and how to treat ophthalmia neonatorum.

Etiology.—By far the greater number of the cases of ophthalmia neonatorum are caused by the entrance of the gonococcus into the conjunctival sac of the infant at the time of, or very shortly after, birth. This assertion has been proven to be true by the researches of Zweifel,[4] Widmark,[5] Welander,[6] Leopold and Wessel,[7] Kraus,[8] Andrews,[9] and many others. Widmark mentions two forms of ophthalmia neonatorum, of which one only is due to the gonococcus. His views correspond with my own in this respect. In seventeen cases of ophthalmia neonatorum that have been examined by me at the Ophthalmic and Aural Institute, recently, the gonococci were absent in two; these two cases developed about two weeks after birth, and were of a mild type. That the constitutional effects peculiar to gonorrhœa may accompany ophthalmia neonatorum is demonstrated by the case reported by Lucas:[10]

[illegible]

[6] Centralbl., f. Augenheilk., May, 1882, p. 134.

[illegible]

A child, eighteen days old, suffering from ophthalmia neonatorum, was brought to Gay's Hospital on account of an affection of the joints. The mother had had a thick purulent discharge from the genitals some time before the child was born. The child was undoubtedly infected during labor. The left knee was swollen and puffed out by an effusion into the joint. A synovitis at the wrist also existed.

Lucas is of the opinion that as synovitis from gonorrhœa of the urethra is probably due to the passage of the gonococci through the lymph-channels, the same may occur in gonorrhœa of the conjunctiva.

Landau [1] has inoculated the healthy urethra with pus obtained from the conjunctiva in a case of ophthalmia neonatorum; gonorrhœa of the urethra followed.

In regard to the number of the cocci contained in the secretions during the various stages of blennorrhœa of the new-born, I have found the following to be the rule: In the early stage, when the discharge is muco-purulent, the cocci are proportionately most numerous. They are then seen in the nuclei and at the margins of the epithelial cells, on the surfaces of and in the pus cells. When the discharge is very profuse their number is relatively less. They disappear entirely only when the discharge of pus has ceased.

Ophthalmia neonatorum due to the presence of the gonococcus is of very varying degrees of severity. The cause of the blennorrhœa can only be determined positively by an examination of the secretion with the microscope. I cannot agree with Andrews in his statement that gonorrhœal ophthalmia is nearly always severe. In six cases recently examined by me, where the gonococci were found, only two were severe. Ulceration of the cornea occurred in one case, but did not perforate. As to the manner in which ophthalmia neonatorum is contracted, Saemisch thinks that during long and tedious labors the infectious material may work itself between the lids. The first bath is probably a very fertile source of infection (Königstein). Unclean hands, sponges, towels, wrappings, etc., are also means for carrying the infectious material.

The chronicity of gonorrhœa in the female is a well-established fact, as indicated by the papers of Bockhart,[2] Currier,[3] and others; hence the appearance of ophthalmia in children, the mothers of whom have experienced the acute symptoms of gonorrhœa years before they became pregnant.

Prophylaxis.—Before the adoption of Credé's [4] method, Bischoff, of Basle,[5] Haussman,[6] Olhausen (Königstein), Credé, and others, practised douching the vagina with a one per cent. solution of carbolic acid at intervals during the first stage of labor. Bischoff, Hausmann, and Olhausen washed the eyes of the infant with the same solution, either immediately after birth or just after the first bath. Credé used a solution of boracic acid—1 to 60—and cleansed the eyes immediately after birth. These procedures greatly lessened the number of cases of ophthalmia neonatorum, but did not abolish the disease. In 1880 Credé began the use of nitrate of silver in the following manner: A small drop of a two per cent. solution was instilled into the conjunctival sacs of the infant, immediately after it had received its first bath. In some cases the reaction following was quite severe, necessitating cold applications to the lids. No serious complications, however, ever occurred. This method resulted in virtually abolishing ophthalmia neonatorum from the clinic. With 7.8 per cent. before, Credé had only about 0.31 per cent. of cases after adopting the use of the silver. The splendid results obtained by Credé were also obtained by Leopold and Wessel, Brunner and Pfeiffer,[7] Professor Schatz, Garrigues,[8] and many others.

A reference to the papers of Oppenheimer [1] and Kreis [2] is sufficient to explain the great efficacy of a two per cent. solution of nitrate of silver, when employed at this particular time. The silver is a simple germicide, and serves to kill the cocci that have found their way into the conjunctival sac of the infant.

In the papers on the prophylaxis of ophthalmia neonatorum I have seen no mention of the use of a solution of sublimate either for douching the vagina or for cleansing the eyes of infants immediately after birth. As sublimate, even in a solution of 1 to 10,000, is an active germicide, I cannot see why it should not be efficacious when employed as mentioned. That it is efficacious is largely established by the following: During my service of two and one-half years at the Emigrant Hospital, a system of treatment for the prevention of ophthalmia neonatorum was adopted which resulted in the complete disappearance of the disease from the lying-in wards of that institution. When labor pains became marked the patient was sent from the waiting ward to the lying-in room, where she was bathed and was given a vaginal douche of from one to two pints of a 1 to 2,000 sublimate solution, care being taken to cleanse the vagina thoroughly. Immediately after the head was born the eyes were bathed with a solution of sodium chloride, about ten per cent. The sublimate solution was sometimes used to wash the eyes also. The results here attained would indicate that if the vagina is thoroughly freed from the cocci before the second stage of labor begins, there is little danger of infection to the infant. The second step in this method is simply one to insure cleanliness.

Since the results of ophthalmia neonatorum are so disastrous, it is clearly the duty of every obstetrician to employ some efficient means for its prevention. Either of the above methods are simple and easy of application.

Treatment.—The treatment of ophthalmia neonatorum is the same, whether due to the gonococcus or to some other agency. I shall discuss it from a bacteriological standpoint, and in order that we may understand the conduct of the gonococcus in relation to the tissues involved, and the effect of certain remedial agencies on these micro-organisms, I shall give the researches of Bockhart, Oppenheimer, and Kreis, so far as they relate to these points.

Bockhart injected a portion of a pure culture of gonococci, fourth generation, into the urethra of a paralytic. Forty-eight hours afterward the meatus was red, and on pressure a drop of pus exuded which contained numerous cocci. The patient died eight days after the inoculation. On section the right kidney was found to contain many abscesses; left kidney normal. The mucous membrane of the bladder and urethra, except at the prostatic portion, was greatly congested. Microscopical examination demonstrated the fact that the surgical kidney, cystitis, and urethritis were caused by the gonococcus. The cocci were found in great numbers *throughout* all the affected tissues. White blood-corpuscles, containing the cocci in their nuclei, were found in large numbers deep in the tissue of the corpus cavernosum urethræ.

This case serves to show that the cocci are not confined to the surface of the mucous membranes, but that they attack and penetrate the epithelium, and enter the deeper tissues.

In experimenting with different medicinal substances, as to their effect on pure cultures of the gonococcus, Oppenheimer arrived at the following conclusions: Solutions of the nitrate or sulphate of mercury, 1 to 15,000 retarded development, 1 to 10,000 destroyed vitality; sublimate, 1 to 40,000 retarded development; 1 to 20,000 destroyed vitality; permanganate of potash, 1 to 50 retarded development; 1 to 25 destroyed vitality. The chlorates of potash and sodium were inefficient. Carbolic acid, 1 to 20 destroyed vitality in ten minutes; 1 to 100

[8] Amer. Journ. Med. Sciences, October, 1885, p. 1.

retarded development; creasote, 1 to 2 destroyed vitality quickly; nitrate of silver, 1 to 50 (two per cent.) destroyed vitality. Bromine, chlorine, and iodine in solutions of moderate strength destroyed vitality; methylic and ethylic alcohol, chloroform, sulphuric ether, and glycerine destroyed vitality only when undiluted; tannin and resorcine were ineffective; solutions of the subnitrate of bismuth, acetate of lead, and alum produced no effect; strong solutions of the sulphates of copper, zinc, and iron affected the microbes but slightly; turpentine was effective.

The influence of temperature on the development of the gonococcus is shown by Kreis' experiments with tube cultivations on agar. Below 30° C. no development; 30° C. to 35° C. very slight development; 35° C. to 42° C. develop rapidly; 42° C. to 48° C. develop slowly; 48° C. to 50° C. no development. An hour and a half in a temperature of 48° to 50° C. renders the microbe incapable of development. The effect of medicinal substances on the microbes Kreis found to be as follows: Nitrate of silver, one-half per cent., microbes did not develop; one per cent., microbes did not develop; sublimate, 1 to 20,000, development; sublimate, 1 to 10,000, no development; sulphate of zinc, one per cent., development; sulphate of zinc, carbolated, one per cent., no development; sulphate of copper, one per cent., no development; acetate of lead, one fourth per cent., development; acetate of copper, one per cent., development; alum, strong solution, development; chlorate of potash, five per cent., development; tannin and resorcine, one per cent. solutions, development; carbolic acid, five per cent., development; thymol, 1 to 1,100, no development; chloride of lime, one per cent., no development.

It is of interest to know how the remedial agents indicated as the best for the treatment of ophthalmia neonatorum, by the influence that they exert on the gonococcus, as shown by the experiments with the pure cultures, correspond to the remedies that experience has indicated as most efficient. For this purpose I have given a brief synopsis of the treatment advised by some of the various writers.

Mackenzie:[1] Eyes to be cleansed three or four times a day with a wash composed of sublimate, gr. j.; chloride of ammonium, gr. vj. to xij.; water, oz. viij. to xij. A solution of the nitrate of silver to be applied to the conjunctiva every six to eight hours. Solution, gr. ij. to x. to the ounce, not to be used if the cornea is affected. In one case two applications of the silver, made on the first and second days of the discharge, stopped the discharge. To preserve the lids from sticking together he employs an ointment of the red precipitate of mercury. A blister behind the ear is thought to be beneficial.

Stellwag:[2] If the secretion is profuse, "lead water" may be instilled between the lids. He recommends a solution of tannic acid as an application to the conjunctiva, but says that we may do still better by employing a 1 to 3 gr. solution of the nitrate of silver.

Wells[3] recommends a collyrium of alum and zinc (alum, gr. iv.; sul. of zinc, gr. ij.; water, ℥ j.) to be injected into the eye every fifteen to thirty minutes during the day; applications of the mitigated stick of the nitrate of silver to the conjunctiva once every day if the patient can be seen by the physician. Citrine ointment to the lids. In severe cases, leeches, scarification, and cold compresses.

Nettleship[4] advises washing the eyes frequently. Collyria of the sulphate or chloride of zinc, alum, or sublimate used every one to three hours; solutions of the nitrate of silver (gr. ij. to ℥ j.) applied from four to six times a day. Strong solutions of the nitrate of silver, or the mitigated stick, should be used in all severe cases, unless especially contraindicated, to shorten the disease; local cold by ice compresses, leeches to the temple, canthotomy if the swelling is intense, or scarification of the conjunctiva. He does not use strong solutions of silver until the discharge has become profuse. Corneal ulceration does not contraindicate the use of strong solutions of silver.

Julin:[1] To reduce pressure on the cornea, scarification of the conjunctiva, canthotomy, or vertical division of the upper lid as advocated by Mr. Critchett. "To cut short the inflammatory process, the best and most effectual treatment consists in the application of the solid nitrate of silver to the inner surface of the eyelids once in twenty-four hours, combined with the constant application of iced carbolized water and frequent ablutions of the conjunctival sac." The above quotation applies to gonorrhœa of the conjunctiva in the adult. A four to seven per cent. solution of the nitrate of silver is employed in ophthalmia neonatorum, instead of the solid stick. Uses carbolized water for cleansing the eyes, atropine if the cornea is affected.

Schmidt Rimpler[2] recommends constant cold applications to the lids, and the use of solutions of the nitrate of silver, or the mitigated stick, applied to the conjunctiva.

Dr. Abadie[3] favors the application of a three to four per cent. solution of the nitrate of silver to the conjunctiva every twelve hours, and says that it is an error to wait for the period of most profuse discharge before making the application. If the corneæ are threatened, must increase the frequency of the cauterization, must use ice compresses constantly.

Kianitzin[4] obtains good results from the use of a 1 to 2,000 solution of sublimate.

Landesberg[5] recommends solutions of boracic acid and a two per cent. solution of the sulphate of zinc in mild cases. Must use ice-cloths constantly if the swelling is intense; nitrate of silver, two to three per cent. solution, applied to the conjunctiva every twenty-four hours after the purulent stage is reached. Leeches canthotomy and eserine are recommended in severe cases.

The plan of treatment followed at the Ophthalmic and Aural Institute, is as follows: The conjunctival sacs are cleansed thoroughly every half hour, or more often if the discharge is profuse; constant applications of cold to the lids by the use of small pieces of linen, which are placed on a cake of ice near the patient, and are changed to the eyes every half minute, or as soon as the piece on the lid becomes warm another piece is substituted. The conjunctivæ are brushed with a one to two per cent. solution of the nitrate of silver morning and night, commencing when the discharge becomes profuse. If corneal complications arise, one or two drops of a one-half per cent. solution of atropine are instilled twice or three times a day.

In the plans of treatment recommended by the authorities mentioned, we find them agreed in the use of certain measures, namely, strict cleanliness, solution of the nitrate of silver, and hot or cold applications to the lids. It needs no argument to establish the advisability of cleanliness. The experiments of Oppenheimer and Kreis have demonstrated the fact that solutions of the nitrate of silver are active germicides against the gonococcus; and the experiments of Kreis, that a low or a high temperature prevents the development of the gonococcus. We find that the proper employment of these three factors is all that is necessary to meet all the indications in the treatment of ophthalmia neonatorum when the case is seen before perforation of the cornea has taken place. The duration of gonorrhœal ophthalmia, occurring in the infant (ophthalmia neonatorum) or in the adult, may be limited or cut short by proper treatment, the time required depending entirely on the extent to which the

gonococci have penetrated the tissues of the lid, the destruction of corneal tissue if the cornea is involved, and the rapidity with which the cocci are expelled from the tissues by the discharge of pus—the effort of the system to rid itself of the irritating agent. The so-called abortion of these conditions is simply a cutting short of the disease in its earliest stage. The following is an illustrative case:

Henry D—— came to the clinic at the Ophthalmic and Aural Institute, April 17th, at 2 P.M. On the morning of the same day patient noticed that the eye was painful and discharged a little mucus. When I saw the patient, a little after 2 P.M., the right eye was discharging muco-pus quite freely—conjunctiva of the left eye slightly congested. An examination of the secretion with the microscope showed gonococci in large numbers. A thorough application of a two per cent. solution of the nitrate of silver was made to the conjunctivæ of both eyes, and constant applications of iced cloths, with frequent cleansing of the lids was ordered. At 11 P.M. the lids of the right eye were much swollen. April 18th: Lids but little swollen; cold applications constantly day and night. April 19th: No discharge from the left eye; very slight discharge from the right eye. A second application of the nitrate of silver solution was made; cold continued. April 21st: No discharge; conjunctivæ only slightly congested. Patient discharged.

After the gonococci have penetrated the epithelium and have entered the lymph-channels we cannot expect to destroy them by a simple application to the surface of the conjunctiva; hence the necessity of employing some agency that will prevent their development, and at the same time will not interfere with the action of the tissues in their attempt to expel them. We have this means in the iced cloths employed, by the application of which we are enabled to reduce the temperature to the point desired. Heat may also be employed, but the rapid destructive changes in the tissues that sometimes occurs when the temperature is elevated, and the fact that cold applications are usually better tolerated by the patients, renders the latter more generally applicable.

The experiments of Kreis indicate that the coccus does not develop, or develops but slowly, at a temperature of 90° to 92° F. According to numerous tests that I have recently made, I find that the temperature of the conjunctival sac, in the various degrees of inflammation, ranges from 98° to 102° F. I also find that by constant cold applications the temperature of the conjunctival sac may be made 88° to 94° F., according as the lids are little or much swollen; this with the temperature on the surface kept at about 40° F. This reduction of temperature certainly retards the development of the gonococci, while it does not seem to interfere with the tissue-change necessary to expel them.

Taking into consideration what has preceded, the plan of treatment which I deem most rational is as follows, for the careful carrying out of which a trained nurse or a careful attendant is essential:

If but one eye is attacked, the well eye must be carefully guarded against the possibility of infection from the diseased eye. This is done by cleansing both eyes frequently with absorbent cotton or clean sponges, and clean, cool water, weak solutions of sublimate, boracic acid, etc. Sealing the eye in infants is very unsatisfactory; it may be done with benefit in adults. *Constant* cold applications to the lids should be made. I find the following method most efficient: Pieces of linen, twelve or eighteen in number, are folded into three layers, so as to form squares of an inch and a half. These squares are dampened and spread on a cake of ice. The nurse in attendance changes the pieces of linen to and from the eye sufficiently often to have a cold piece *always* resting on the lids. These applications are kept up *constantly* until the swelling of the lids subsides, and until the discharge has almost entirely ceased, usually from three to seven days. The plan of making the cold applications at intervals of two or more hours is certainly not advisable in these cases, as the temperature of the lids rises as soon as the cold is removed, and the development of any living germ in the tissue of the conjunctiva is resumed. I have witnessed the increase of inflammatory action in cases of this kind when the intermittent plan was followed. The secretion is removed from the conjunctiva by careful washing with cold or cool water, a clean sponge or absorbent cotton, usually every twenty or thirty minutes—more or less frequently according as the secretion is more or less profuse. Andrews' perforated speculum is a dangerous instrument in the hand of the nurse or the general practitioner, and although when properly used it may remove the secretion as well or better than any other method, it should only be used by one skilled in the manipulation of the lids. In these conditions applications of a one to two per cent. solution of the nitrate of silver are made to the surface of the conjunctiva every morning and evening, care being taken not to make the solution sufficiently strong to cause an increase in the inflammation of the lids when it is applied. The applications are made in the following manner: The lids are everted, and the solution of silver is brushed on the conjunctiva freely, with a soft camel's-hair brush. After the silver has remained in contact with the conjunctiva for fifteen to thirty seconds, it is washed off with a very weak solution of sodium chloride or simple water. The above-mentioned applications may be made in all stages of the disease, without regard to the condition of the cornea. If corneal ulcers exist, one or two drops of a one per cent. solution of the sulphate of atropine should be instilled between the lids two or three times a day. I find that the gonococci are present so long as the purulent discharge continues.

If the above plan of treatment be carefully carried out I am confident that no eyes need be lost by any form of gonorrhœal ophthalmia, if the treatment is commenced before the cornea becomes involved, and that corneal complications will be very rare. In nearly every case the progress of the disease will be arrested from the moment that treatment is begun. Canthotomy, Critchett's operation of a perpendicular incision through the middle of the upper lid, or scarification, I deem harmful and entirely unnecessary.

We may sum up as follows:

1. Ophthalmia neonatorum is one of the most productive causes of blindness.

2. By far the majority and all the severer forms of ophthalmia neonatorum are due to the presence of the gonococcus.

3. This disease is contracted during or shortly after the birth of the child.

4. Proper prophylactic measures may prevent its occurrence.

5. Ophthalmia neonatorum and gonorrhœal conjunctivitis in the adult are very variable in the degree of severity.

6. Both forms of this disease may be controlled and shortened in any of their stages by proper treatment.

Subcutaneous Injections of Citrate of Iron.—Dr. Mori recommends very highly the hypodermatic administration of citrate of iron in anæmia. In a pregnant woman with very marked anæmia great improvement followed daily injections of a syringeful of a one per cent. solution into the gluteal region. At the end of two weeks the patient was practically cured. In another pregnant woman eight injections sufficed to bring about a very great improvement. In a woman, fifty four years of age, suffering from a very severe degree of anæmia, induced by hard work and poor food, twenty-five injections were required before any satisfactory amelioration was to be noted.—*Centralblatt für Gynäkologie*, June 5, 1886.

CASTS AND ALBUMEN IN PROSTATITIS.

By C. DREW, M.D.,

JACKSONVILLE, FLA.

IN THE MEDICAL RECORD of February 13, 1886, in a letter from the special London correspondent, the following lines appeared:

"At the Clinical Society Sir Andrew Clark related a unique case of acute prostatitis, which had been seen by Sir James Paget and himself. During the whole course of the case the urine was found to contain hyaline cylinders and small, flask-shaped hyaline masses, which were in some cases connected with the cylinders. The casts were of the same character as those found in the urine in acute nephritis or acute congestion. An important diagnostic point was the presence of flask-like bodies attached to the hyaline cylinders." "He had met with two other cases which were similar, but less acute." The question naturally arises in the mind as to whether the structure of the prostate is of such a character as to develop a disorder moulding a plastic secretion, and its formation into cylinders or casts. Henle divides the prostate into "three portions—the two sphincters of the bladder; a tough, yellowish, muscular membrane; and the gland proper. The latter covering," he states, "sends off into the gland, a number of processes, forming a massive framework, and forming a considerable portion of the whole organ." "The separate elements of the gland, in number from fifteen to twenty, appear to be of the racemose kind. In them we find pear-shaped vesicles 0.1204 to 0.23 mm. in diameter, lined with columnar epithelial cells. The ducts of the gland are five, surrounded by a muscular coat. . . . They empty themselves singly, by fifteen or twenty openings, into the urethra."

"The sinus prostatica is a slender saccule, from 7 to 14 mm. in length, lying in the substance of the prostate gland. . . . It opens at the summit of the cannuliculi seminales, between the orifices of the ejaculatory ducts. The secretion of the prostate is probably allied to that of the vesiculæ seminales. In both we find albuminous matter, barely soluble in acetic acid" (Frey, "Histo-chemistry of Man"). We at once refer to Sir Andrew Clark's description of the pear-shaped hyaline masses, and compare it with Frey's description of the pear-shaped vesicles in the prostate. If plastic secretion is moulded in pear-shaped vesicles and thrown out as casts, many of them would doubtless retain their flask- or pear-shaped appearance. As the prostatic vesicles are lined with columnar epithelium, we would also expect to find another point of similarity to casts from the kidneys, namely, the presence of epithelia accompanying the casts of pear- or flask-shaped epithelial casts. So far as the writer is aware no mention has thus far been made of such bodies as having come from the prostate.

If such vesicles can form casts, we naturally infer that the prostatic sinus would also form them, and in confirmation of this, Drs. Van Buren and Keys, in their work on "Genito-urinary Diseases, with Syphilis," 1881, folio 247, state, in the article on "Acute Parenchymatous Prostatitis," "a false membrane may form in the prostatic sinus, but this is exceedingly rare."

Can prostatitis, like nephritis, give rise to albuminuria? There have been many cases of transient albuminuria reported, for which it has appeared difficult to account, and there is good reason for the suspicion that acute prostatitis, with albuminuria, may be confounded with acute nephritis. We repeat briefly the quotation from Frey, made above: "The secretion of the prostate is probably allied to that of the vesiculæ seminales; in both we find albuminous matter freely soluble in acetic acid." We append briefly a report of two cases illustrative of such a possibility. Both were cases of acute prostatitis, occurring in persons of amorous disposition, but rather continent habits. No combination of circumstances is more likely than this to induce prostatic trouble—a failure to relieve sufficiently often one of the most urgent calls of nature.

Mr. C——, of amorous disposition, but continent habits, had been for about a year troubled with slight vesical irritation. In the summer of 1884, being much debilitated from overwork, he was attacked by lumbago and intense vesical irritation, the urine being passed for several days in small quantities, and at intervals of about fifteen minutes. Examination with heat and nitric acid revealed a large percentage of albumen—about one-fifth the total bulk as it stood in the test-tube; no casts were found after a careful microscopic examination. In six weeks, or less time, all albumen had disappeared, leaving evidences not to be doubted of subacute prostatitis, viz., urethral hyperæmia, vesical irritation, abnormal erections, anæsthesia of glans penis, fulness and soreness in the rectum, and tenderness over the pubes. At this time an examination of the urine was made—chemically and microscopically—by an expert in such matters, who stated that there was no evidence that he could see of any disease of the kidneys having existed. This patient still has prostatic disease, but no tangible evidence of any kidney lesion. The inference is, that during an attack of acute inflammation the prostate gland secreted copiously, perhaps mixed with a secretion from the vesiculæ seminales, and that this gave to the urine, with the usual tests, an albuminous reaction.

Mr. W——, widower, of amorous disposition, became involved in *une affair de cœur*, which, after much excitement and prolonged waiting, gave negative results as far as his gratification was concerned. It was, however, followed by acute prostatitis, and much vesical irritation. In this case there was no suspicion of kidney disease, the history of the case having at once directed attention to the prostate; but, led by past observation, an examination was made of the urine, and a decided, but not copious precipitate of albumen found. In this case the attack was much less acute than in the first, and the amount of prostatic secretion perhaps much less. After a prolonged attack of prostatic trouble, assuming various phases, with many acute exacerbations, he has finally been restored to health, although up to the present time he finds it necessary to use extra precautions to avoid a recurrence of his old attacks.

A CASE IN WHICH VISION WAS TOTALLY OBLITERATED BY A GUN-CAP IN THE EYE.

By DAVID WEBSTER, M.D.,

PROFESSOR OF OPHTHALMOLOGY IN NEW YORK POLYCLINIC; SURGEON TO MANHATTAN EYE AND EAR HOSPITAL.

AN iron-moulder, aged thirty-five, residing near Sing Sing, on Saturday, November 14, 1885, at 10 A.M., attempted to remove the cartridge from a breech-loading shot-gun. The cartridge exploded and the cap struck him in the right eye, destroying the sight immediately. He was, without delay, sent to Dr. C. R. Agnew, at the Manhattan Eye and Ear Hospital, and on his arrival at that institution, a couple of hours later, he was examined by Dr. G. W. Hale, then the House Surgeon, now of Nashville, Tenn., who found that the gun-cap had passed through the upper eyelid and through the upper part of the ciliary region, a little to the outer side of the vertical meridian, the wound being irregular in shape and approaching to within an eighth of an inch of the corneal margin. The eye was without perception of light. The anterior chamber was filled with blood. He was seen later, on the same day, by Dr. Agnew, the conditions remaining unchanged.

I saw the patient, with Drs. Agnew and Hale, on Sunday morning—the morning after the injury. Then, as it seemed almost certain that the cap was in the eye, and as a good deal of inflammatory reaction was setting in, we agreed that the eye ought to be enucleated at once. As Dr. Agnew had an engagement elsewhere, he re-

quested me to perform the operation. Accordingly, assisted by Drs. Hale and King, I placed the patient under ether and enucleated the eye. I opened it on the [illegible] I found the whole of the interior of the globe filled with dark-colored fluid blood and blood-clots. The retina was not detached. The cap was found with its concavity backward, its sharp circular edge embedded in the retina and including the optic-nerve entrance. It was stuck so firmly in this position that it required some force to remove it with forceps.

The reason for the total obliteration of vision in the eye from the time of the injury was now evident. The edge of the gun-cap had cut off all communication of the retina with the optic nerve. Strangely enough, the gun-cap retained its original shape almost perfectly. The patient recovered promptly, and a week later was sent home wearing an artificial eye.

Clinical Department.

AN IMPROMPTU PUMP FOR STOMACH IRRIGATION.

Dr. Sara E. Post, of New York, sends us the following: Having recently a case requiring a stomach irrigation, I tried the funnel with the tube arranged as a siphon, in the manner usually recommended. The end of the tube with the funnel was elevated when pouring the water in, and depressed to induce its escape. The conditions were as perfect as possible, the portion of the tube outside of the body being longer than that lying within. When the tube was first depressed the water ran out freely, but it was found that, as a rule, the stomach was not completely evacuated by means of it. After the flow had ceased, manipulation of the epigastrium would cause it to recommence. Apparently the tube, either by not being introduced far enough, or by being introduced at too great length, and curling upon itself, would fail to reach the most dependent part; and as it is difficult to calculate the depth of the dilated stomach, this objection could not be overcome. As a weak solution of the bicarbonate of soda was used for the injection, the washing would be followed by several watery evacuations, apparently due to the cathartic action of the retained salt. Also, the water removed by the siphon would be almost clear, while from the history of the case it was expected that mucus would be withdrawn.

Some kind of a force-pump seemed necessary to accomplish the desired purpose, and having a stop-cock with two outlets, a rubber piston syringe, a stomach-tube, and some additional tubing, a suitable apparatus was readily arranged. The three arms of the limb containing the stop-cock were provided with tubing, the inlet was connected with the syringe, one of the outlets attached to the stomach-tube by a short intervening glass, and the other connected with the weight from the receiving tube of a Davidson's syringe, and sunk in the receptacle containing the fluid to be injected. It will readily be seen that by manipulating the stop-cock water could be withdrawn from the receptacle and injected into the stomach, or withdrawn from the stomach and injected into the receptacle. Compared with the siphon this method was most successful. The water withdrawn during the first washings was gray, from its admixture with mucus. The washings were no longer followed by diarrhœa, and relief of the symptoms was early obtained. After six washings mucus is no longer returned in the water, a localized tenderness of several years' standing has disappeared, discomfort so great as to interfere with sleep and to make the patient dread food has been lost, and digestion has apparently been re-established. The patient eats three meat meals per day, and is commencing to have a healthy desire for food. It might be added that the patient had previously been under the care of good physicians, and presumably had obtained all of the benefit which medication could give.

The washings are done three times a week, the patient taking no solids for six hours previously. Food could, however, be withdrawn by means of this apparatus, if the bore of the syringe and of the limb containing the stop-cock were sufficiently large. One quart of fluid is first injected and then withdrawn, the injection being repeated two or three times at each sitting. The introduction of the stomach-tube occupies but a few seconds. It seems better to force it down quickly, without much attention to efforts at regurgitation, as, when in position, the patient is comfortable, and breathes and talks with complete ease.

Previous spraying of the fauces with a four per cent. solution of cocaine facilitates the introduction of the tube.

This apparatus is, of course, not new. Its principle is exactly that of the ordinary stomach-pump. It is presented simply because while answering the same purpose it can be more cheaply gotten up.

AN INSTANCE OF SEEMINGLY UNUSUAL SUSCEPTIBILITY TO ETHER.

Dr. George W. Squires, of East Avon, N. Y., reports the following case: Mrs. W——, forty-five years of age, housewife, fell down stairs, striking her face against the railing, from which she sustained quite a severe contusion of the right cheek, with effusion of blood under the conjunctiva from the outer canthus to the margin of the cornea. When first seen she was suffering from a slight frontal headache, for the relief of which the writer applied to the forehead not more than six or eight drops of sulphuric ether with a camel's-hair brush. The patient at once said, "That is ether, and it is putting me to sleep," and in less than half a minute she was fully under the influence of the anæsthetic, remaining unconscious for several minutes, and upon recovery, and for some time afterward, presented all the symptoms following profound and prolonged etherization. She could not have inhaled more than three to five drops of the ether, as it was immediately washed from her forehead.

THE DESTRUCTIVE ENERGY OF THE TINCTURE OF THE CHLORIDE OF IRON ON THE TEETH.

An original paper of conspicuous merit, with the above title, was read before the Odontological Society of the State of New York, in June, by George W. Weld, M.D., D.D.S.,

As the researches of Dr. Weld in this direction possess many points worthy of the careful consideration of every physician, the salient features of the paper are presented to our readers.

Dr. Weld declares that the clinical operation shows that water increases the destructive energy of the tincture of the chloride of iron upon the enamel of the teeth more than any other fluid, and, as an illustration, he states that the effect of adding water to a simple solution of the chloride of iron, *devoid of free acid*, is to give basic salts of iron and the separation of free hydrochloric acid.

Dr. Weld showed conclusively that the tincture of the chloride of iron of officinal strength had but little, if any, effect upon the enamel structure of a tooth when immersed in the same for a period of twelve hours; but that, when immersed in a solution of the tincture and water, in proportion of one ounce of water to one drachm of the tincture, the enamel was materially injured in five minutes.

As an illustration of this phenomenon the doctor stated that when a piece of zinc is immersed in strong sulphuric acid (H_2SO_4) it has been observed that the acid has no effect upon the structure of the zinc, but if a little

water be added to the acid, the zinc is at once destroyed; so that it is not entirely a matter of the strength of the fluids, so far as the quantity of iron or acid is concerned, but a matter of construction or solubility. The zinc in the strong sulphuric acid is protected in the same manner that the tooth which is immersed in the strong tincture of chloride of iron is protected, viz., the surface is blocked up with the basic salts of iron insoluble in alcohol, which prevents chemical action. In the case of the zinc, it is the sulphate of zinc resulting from the first action, and insoluble in the concentrated acid, that forms a protecting coat over the surface of the zinc; the addition of water dissolves this protecting sulphate, and renders further chemical action possible. In the case of a tooth immersed in a strong solution of the tincture a similar action takes place, viz.: the oxide of iron first formed protects the enamel from immediate chemical action on account of its compact adherence to its surface.

To illustrate still further, Dr. Weld called attention to two specimens of teeth on the card [1] which had been immersed in the tincture and alcohol, and compared them with teeth which had been immersed with the tincture and water. Here it was observed that, although the alcoholic solution used contained the same quantity of the tincture and possessed apparently the same relative strength, and the teeth immersed for the same length of time, yet no injurious effect was produced on their lime salts. The reason is attributed to the fact that alcohol is a dehydrating compound, and the peroxide which is formed in the alcoholic solution is of the anhydrous form, and in character very compact, adhering closely to the surface of the tooth, thereby preventing immediate chemical action; while on the other hand, in the presence of water, the peroxide, which is precipitated in the hydrated form and is flocculent in character, does not so well adhere to the surface of the tooth, leaving the free hydrochloric acid in the solution to unite with the lime salts with greater facility.

There appears, then, to be two forms of peroxide of iron, viz.: 1, the hydrated form ($Fe_2(OH)6$), found in the water solution, which is flocculent and non-protecting to the teeth; 2, The anhydrous form (Fe_2O_3), formed in the alcoholic solution, which is heavy and compact, and protects the surfaces of the teeth. The following formula will show how the hydrated peroxide is formed from the anhydrous peroxide ($Fe_2O_3 + 3H_2O = Fe_2(OH)6$).

Synonyms: Ferric hydroxide.
Hydrated sesquioxide of iron.

The teeth immersed in an ounce of the elixir of the pyrophosphate of iron, with one drachm of the tincture of the chloride added, for a period of twenty-four hours, produced apparently no chemical effect on the enamel; but with the same quantity of water and the tincture the enamel was completely destroyed. The elixirs are composed of nearly twenty-five per cent. of alcohol, the presence of which, as observed in the strong solution of the tincture and in the alcoholic solution, affords a protection to the enamel of the teeth in the manner described. But it is to be noted that when a tooth is immersed in a solution of the tincture and simple syrup, in the above proportions, the enamel is but little affected. This is due to a mechanical reason, or a condition of fluidity of the solution, *i.e.*, the presence of the sugar in solution coats the surface of the enamel, preventing the chemical affinity between the acid, or perchloride of iron, and the lime salts in the teeth.

The manner in which syrup modifies the destructive energy of the tincture on the enamel was beautifully illustrated by the effect produced on the specimens of teeth which had been immersed in three different weak solutions of phosphoric acid. Two of these were proprietary medicines and contained water, and the effect was to injure the enamel of a tooth in one hour; while the third, a syrup solution (each fluid drachm containing two grains of free phosphoric acid), produced but little, if any, injurious effect on the enamel in twenty-four hours.

Equally interesting was the effect produced on the enamel of teeth which had been immersed in a solution of the tincture and the weak alkaline waters (notably Vichy).

When a drachm of the tincture is added to an ounce of the Vichy water, a slight effervescence occurs, indicating that the bicarbonate of soda contained in the water has neutralized a part of the free acid contained in the tincture; in consequence, when a tooth is immersed in such a solution, the destructive energy of the iron is, to a great extent, modified. Unless the specific nature of the tincture of the chloride of iron is materially affected (and the peculiar odor of the tincture remains), there seems to be no reason why this preparation of iron, at least in all cases of anæmia, should not be administered in combination with Vichy water.

There are, then, three menstrua which may be employed to modify the destructive energy of the tincture of the chloride of iron on the enamel of the human teeth. The first is alcohol in some form. The second is Vichy water, which neutralizes to a slight extent the free acid contained in the iron. And the third is some form of an elixir or simple syrup.

[1] A glass slip presented to the Odontological Society, containing [illegible] teeth, showing such various modifications the destructive energy of [illegible] and iron compounds on the enamel.

Progress of Medical Science.

Scarlatinal Nephritis.—Scarlet fever derives most of its dangers from disorders that complicate or succeed it. Of these the most important are derangements of the kidneys, and a number of recent writers assert that these organs are constantly affected in scarlet fever. In an article on this subject, in the July number of *The American Journal of the Medical Sciences*, Dr. I. E. Atkinson, of Baltimore, maintains that future research may show that simple renal catarrh accompanies all cases of scarlatina, but it is certainly not true that renal alterations, competent to excite albuminuria or to reveal themselves *post-mortem* to reasonably careful inspection, are invariably present. Renal catarrh, however, is much more frequently an accompaniment of scarlatina than is generally supposed. It usually escapes observation, as it is only exceptionally revealed by symptoms, and can only be recognized after microscopic examination of the urine, a procedure too often neglected, but of the greatest importance as often anticipating dangerous processes that may be averted by timely treatment. Its clinical history, pathological anatomy, and most approved method of treatment are fully considered.

The Functions of the Membrana Tympani Illustrated by Disease.—Sir William Dalby, in a brief but instructive article in the July issue of *The American Journal of the Medical Sciences*, maintains that our knowledge of the functions of the membrana tympani may be added to by the observation of this structure when it becomes altered by disease. He points out that structural changes in the tympanic membrane, as, for instance, extensive calcareous deposit of a very extensive nature, may exist without impairment of hearing. The history of cases in which there have been such deposits, with diminution of hearing, shows that the patients have at some previous period suffered from inflammation within the tympanic cavity, so that the changes then wrought will sufficiently account for the failure in hearing. That the position of the obstacle to hearing is in the conducting media, and, therefore, in the tympanic cavity, and not in the nervous structure, can be in such cases readily demonstrated by experiments with the tuning-fork. Loss

of continuity in the tympanic membrane, he also shows, does not necessarily interfere with its function, provided that the ligamentous support which it affords to the chain of ossicles is not impaired. In several instances in which the membrane has been accidentally pierced with a very sharp-pointed object, as a pin, the hearing has not been found, with the most careful tests, to be injured. In these examples the healing process occupied from three to four days. In one case, when a sudden explosion near the ear ruptured the membrane in two places, the hearing was perfect, and the ruptures healed in a few days. On comparing the notes of other cases in which the hearing was impaired by explosions, it was found that the hearing suffered more injury when the membrane was not ruptured than when it was. It would almost seem from this that the force of the explosion expended itself partially in rupturing the membrane, and so, in a measure, some hearing was saved. At any rate, the author says, it appears to be not an unfair conclusion that the loss of hearing must be due, in all cases, to damage to the nervous structures; in other words, to what, for want of a more accurate term, must be called shock. That loss of continuity in the tympanic membrane does not of itself interfere with its functions is still further shown by the careful and continual observation of cases in which the membrane is perforated by incision or by disease, and the author thinks that the loss of hearing is due to causes which do not include this loss of continuity in the tympanic membrane.

Chronic Hyperplasia of the Oral Mucosa, with Cornification of its Epithelium.—Dr. P. F. Harvey, U.S.A., in the number of *The American Journal of the Medical Sciences* for July, 1886, describes very fully our present knowledge of the clinical history and pathological anatomy of this rare affection, reporting five cases. The cure of any well-marked case is doubtful, but the writer's experience and study lead him to believe that the following method is best adapted to secure that end: Idiopathic and irritative patches, usually expressive of debility, require a restorative regimen and tonic treatment. The use of tobacco in any form should be discontinued as much on account of its general as of its local effects. Alcohol should also be interdicted. All stimulating articles of food, condiments, carbonic acid waters, hot liquids, or solids, etc., must be avoided. General medication should simply be directed toward improving the general health, and topical applications toward keeping the buccal secretions in good condition. Well-marked patches of *leukoplakia* should be treated in the same way, but weak chronic acid solutions may be used in addition. Resort may also be had to the constitutional use of arsenic, at first in tonic doses, but afterward, if necessary and not contraindicated, carried to the point of toleration. The drug, if resort be had to it, must be thoroughly diluted. Weak alkaline washes should occasionally be used once or twice daily, and it is important to persevere in the soothing and restorative plan of treatment for years, if necessary. Ichthyosis of the tongue seems to occur in perfectly healthy and robust men, and in its treatment the question of vital repair may not be one of so much importance. If the patch is not too thick, it may be first brushed with chromic acid solution (1 to 8); or if not likely to be benefited by that application, it may be curetted when clearly diagnosed. It should, in any case, be entirely removed by the galvano-cautery, the sharp spoon, or the knife, if necessary; for, otherwise, the author says, its transformation into cancer is only a question of time.

Serous Poliorrhomenitis.—Under this awkward name Cantani describes the case of a man forty-seven years of age, who had been previously healthy, except for malarial fever and some ulcerations of probably venereal origin. He lived in a dry locality, but was much exposed by his occupation to cold and dampness, and had been addicted to venery and the abuse of alcoholic liquors. Five years before the patient began to be troubled with severe pains in the epigastrium, and he soon noticed a swelling in the abdomen, and, later, enlargement of the lower extremities. There had never been any œdema of the face, or pain in the kidneys, or disturbance of micturition. Examination showed ascites and effusion in the pleural cavities. The spleen was somewhat enlarged, but the heart-sounds were normal, and the liver and kidneys were not diseased. No cause for the trouble could be discovered. Some micro-organisms were found in the fluid, but it was impossible to learn from their appearance the nature of the affection. Some benefit was derived from the exhibition of adonis vernalis.

The Treatment of Gleet.—In an address before the Medical Society of the County of Albany, Dr. O. D. Ball described a method of treatment employed by him successfully in a number of cases of chronic specific urethritis (*Albany Medical Annals*, June, 1886). He employs an ointment composed of oxide of zinc, three drachms; lard, three drachms; simple cerate, two drachms. The application is made by means of an olive-pointed bougie. The constricted portion of the bougie is filled out evenly and as smoothly as possible with the full calibre of the instrument. The bougie should be carried down to the prostatic portion of the urethra as rapidly as possible, and then, after being rotated in both directions, slightly withdrawn and pushed back again, in the hope that some of the ointment will be forced into the swollen mouths of the seminal and prostatic ducts. In the same manner the remaining portion of the urethra should be treated, giving plenty of time for the ointment to be melted and left in contact with the diseased membrane. The patient should have emptied his bladder previous to the application, and should be instructed to refrain from doing so again as long as possible. The applications should be made at least twice a day—in the morning and the last thing before retiring. The instrument should not be too large, but of just sufficient size to smooth out the folds of mucous membrane. For instance, when the penis measures three and a half inches in circumference, a No. 20 French will about answer the purpose. The average time of treatment of all the cases was a little over four weeks. The longest any one case was under treatment was eight weeks; the shortest was ten days, except in one case where the patient never saw any discharge after the first application was made.

Congenital Malformation of the Intestines.—Dr. Owen Pritchard reports the following case in *The Lancet* of May 15, 1886: The child (a female) looked quite healthy at birth, except that the abdomen was unusually distended, and on his visit in the evening the nurse drew Dr. Pritchard's attention to the large size of the abdomen, and stated that the child had been very sick. A teaspoonful of castor-oil was ordered, but at the next visit it was found that it had not operated, and that the sickness was getting much worse, the vomit becoming black and offensive. An injection was tried, but it succeeded in bringing away only a few very small lumps of fæces. The vomiting became more and more severe, and the child died at the end of a little over four days. At the post-mortem examination the stomach was found normal, and the small intestine for about three feet was also normal, but here it ended in a blind extremity which was greatly distended. Then, quite separate from all this, and not attached to it in any way, were coils of very small intestine several feet in length, and not measuring more than a sixth or an eighth of an inch in diameter. This passed on into the right iliac fossa, and there forming the ileo-cæcal valve, it continued in the course of the large intestine on to the rectum, its diameter in any part of its course not measuring more than a sixth of an inch.

A Remedy for Coryza.—Muriate of cocaine two grains, roasted coffee and white sugar of each one ounce. To be taken as snuff.—*Medical Press.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 24, 1886.

A NEW "SYSTEM" OF GASTRIC THERAPEUTICS.

ONE may well listen with respect to the teachings of a physician who has cured over one hundred cases of gastric ulcer. This is what Professor Leube, of Germany, claims to have done (*Bull. Gén. de Thérap.*, January 30, 1886). Professor Leube is a specialist in the department of gastro-enteric pathology. He preaches a gospel of which the three chief points are the need of accurate diagnosis, strict regimen, and copious use of the stomachal siphon. Professor Leube is one of those who have introduced a system into practice, based, like all systems, on the belief that its adoption will cure most cases of the diseases for which it is intended. Already there are establishments in Germany instituted with the sole object of treating gastric disorders according to the *régimes de Leube.*

Professor Leube has had an excellent training in physiological and chemical science, and having devoted himself largely for fifteen years to the subject of digestive disorders, it is not surprising that he should have evolved a "system" that merits some attention.

The therapeutic principles upon which Professor Leube depends are four in number: 1, Dietary regulations; 2, the use of the stomach-tube; 3, the use of hydrochloric acid and pepsin; 4, the use of various other drugs, such as powders, bitters, etc.

Preliminary to all treatment it is considered absolutely essential to make a correct diagnosis of the form of gastric trouble. To facilitate this the stomach-tube is used, and seven hours after a meal that organ is washed out. If there remain any food at this time, it is an evidence of digestive trouble. By using various foods, and then subjecting the stomach to the seven-hour test, a list of most digestible substances is obtained. On the basis of many such experiments Leube constructs his different regimens. They are as follows:

Regimen I. Soup (*bouillon*), meat-juice, milk, raw and soft-boiled eggs, unsweetened crackers, and mineral waters. The digestibility of meat solution as compared with light foods, such as calves' brains, rice, and chicken, was shown by many clinical examples as well as by experiments. A few patients, however, through some idiosyncrasy, cannot digest milk or eggs.

The diet above given is suitable for chronic catarrh and gastric ulcer. After it has been persevered in for about ten days, Regimen II. is introduced; this consists of boiled calves' brains, boiled sweetbreads, boiled chicken, and boiled pigeon. They are digestible in the order given. The chickens must be young and the skin must not be eaten. Well-boiled soups were also permitted, and for the evening repast soups, with milk, tapioca, beaten eggs, and calves' feet. This regimen, to which may also be added Regimen I., gives a considerable variety. Treatment may be commenced with Regimen II. if the stomach-washings show the inutility of the first. The patient should live upon these regimens for several weeks, or until his digestive powers will take care of them easily. Then he enters upon Regimen III.

Regimen III. This consists of Regimen II. with the addition of raw or very rare beefsteak. The best way of preparing it is to scrape as much meat from the raw steak as can be removed easily, and heat it up rapidly in a small quantity of fresh butter. Raw ham scraped and cooked in the same manner is also good, strange as it may appear. The ham must be tender. A small amount of mashed potato is allowed, a little bread (not too fresh), and small quantities of tea or coffee with milk.

Regimen IV. Roast chicken, pigeon, venison, partridge, hare, rare roast-beef (it is best cold), leg of veal, small fishes, maccaroni, and soup, with milk and rice; a small amount of butter in some cases. Later on a small quantity of Bordeaux or Rhine wine may be used, but cautiously. Great variety in diet should not be adopted too rapidly.

The number of meals *per diem* and the quantity of food ingested must be carefully regulated with reference to the seven-hour rule, and the conditions and peculiarities of patients. Leube finds that at the catamenial period digestion is considerably retarded. It should consequently be aided, or a longer time be allowed for it, and the food should be plain and simple.

Regimen IV. should be continued for several weeks, and, if necessary, for months; its conditions should be rigorously adhered to. When it is decided that the patient may return to his habitual diet he is directed to make the change very slowly and to keep himself informed as to his digestive ability by the use of the washing-out tube in all doubtful questions.

The only stomach affection in which dietetics play a secondary part is that which Leube describes as nervous dyspepsia. Patients will, however, do better, even in that malady, to adopt a definite dietary. Regimen IV. is recommended, and variety is advised in the use of it for such cases. Condiments may be used if needed, and hydrochloric acid with pepsin. It should be remembered that in treating nervous dyspepsia moral dietetics (*la dietetique morale*) has a preponderating influence.

Leube attaches considerable importance to giving the stomach certain periods of complete repose. For instance, he will wash out the stomach seven hours after luncheon, and give no more food until ten o'clock on the following day. At this time, soup and beef-steak are given, and, generally, a stomach-washing in the evening will show that the meal has been digested.

The drugs most used are hydrochloric acid and pepsin, bitters, cundurango, and mineral waters. The acid and pepsin are not given in nervous dyspepsia or in cancer

or ulcer. Bitters, including cundurango, are not thought much of, though the drug mentioned is one of the best. Mineral waters are prescribed in very moderate amounts (O ss. daily) and are to be taken slowly upon an empty stomach.

RAYNAUD'S DISEASE.

In The Medical Record of January, 1885, we referred to the articles of Petit and Verneuil upon "Symmetrical Dry Gangrene." The subject was also discussed editorially and elicited a number of contributions. Giovani, an Italian physician, and Bouveret, of Lyons, France (Medical Record, November 14, 1885), reported further illustrations of this affection. Dr. C. L. Dana, in an article on the "Acro-Neuroses" (Medical Record, July 18, 1885), discussed the same subject under the head of "Raynaud's Disease," a local syncope and symmetrical gangrene of the extremities, a history and bibliography of the affection being given, and several cases of the milder type reported. These various articles have excited considerable interest in an affection which is not particularly rare in its slighter forms, but which has not been generally recognized as a disorder of a distinct clinical type. In the *Philadelphia Medical Times* of May 29, 1886, Dr. J. H. Musser reports a classical case, and discusses the history of the disease in an instructive manner. In 1862 M. Raynaud gave a description of the disease to which his name is given, and which he described as a symmetrical local syncope and asphyxia of the extremities, ending sometimes in gangrene. It is characterized by paroxysmal attacks, in which the fingers, toes, and even the tip of the nose, the ears, and tongue become white, bloodless, and feel cold and dead. When the fingers alone are affected the trouble is called *digiti mortui*. In severe cases after a time trophic changes occur, and a slow, dry gangrene sets in. In most cases, even of the mild type, some sensory troubles, such as numbness, prickling, burning, or neuralgic pains are felt.

The gangrene is generally of a slight amount, although sometimes the fingers may have to be amputated.

The disease occurs oftener in women, and in persons between the ages of eighteen and thirty. Chronic uræmic poisoning and chronic malarial poisoning often produce symptoms closely resembling Raynaud's disease, and the malarial infection may even cause a gangrene, according to Petit and Verneuil. The milder forms of *digiti mortui* occur in the paroxysms of hysteria and in neurasthenia.

Raynaud's disease shows some curious alliances. For example, local asphyxia of the extremities is one of the most marked features in one of the types of scleroderma. Dr. Barlow had a case in which the paroxysms of local asphyxia alternated with paroxysms of hæmaturia. Dr. Hutchinson cites a case in which iridoplegia was associated with local syncope, asphyxia, and gangrene of the ears. In a case reported by Weiss the patient had attacks of temporary aphasia, and in a case of Southey's there was an involvement of one of the joints. Various skin disorders, such as urticaria, erythema nodosum, and eczema may alternate with or accompany the disorder.

The morbid anatomy of this disease is unknown. No definite organic changes have been found in the central or peripheral nervous system. It can only be supposed that the vascular neuro-mechanism is in an unstable and over-irritable condition. The result is, that there are paroxysmal contractions of the blood-vessels of the extremities. It is a kind of epilepsy of the sympathetic.

Bearing in mind that uræmia, malaria, syphilis, hysteria, and neurasthenia are often present in this disease, treatment must be directed accordingly. Raynaud speaks highly of the value of the galvanic current. Nitro-glycerine and tonics are also indicated.

AN INFINITESIMAL ORGANISM.

In order to give the student of micro-organisms an idea of the extent to which such a path of research may lead him, there should be set before him the investigations recently made by Rev. Dr. Dallinger, president of the English Microscopical Society, as disclosed in a lecture entitled "The Latest Work among the Least and Lowest Forms of Life," given by him at the Firth College, Sheffield, England. In it he described the result of three years' close study with the minutest forms of life. He stated that he has now microscopic lenses which only five years ago were declared by mathematicians to be impossible of accomplishment. By means of these he demonstrated to his audience shells in a piece of chalk of which it would take four million to make an ounce. In a drop of water he could show a desmid which measured only one millionth of a cubic inch; but this was a giant compared to the smallest organism known, of which within the last few months he has made the discovery and found that the flagellum or motor fibre of this infinitesimal entity is two hundred and four millionth seven hundred thousandth of an English inch. One is awe-struck at such a discovery as this, and it is a question as to which should incite an admiring amazement the most, the minuteness of the organism or the mighty mind that can comprehend it and mathematically demonstrate it. Such a great discovery as this, the smallest known organism, will settle any restless feeling of a scientific Alexander, if such can exist, by showing him that he need not for a long time to come sigh for new worlds to conquer.

MEDICINE IN THE FUTURE.

The late Dr. Austin Flint[1] was appointed to read a paper before the British Medical Association at its meeting in 1886. The manuscript was prepared, but the hand which wrote it is at rest, and the voice which was to have pronounced it is hushed. To those who now read it, the last writing from a busy and powerful pen, it comes with the force of farewell words.

"The meditations of a medical practitioner," he says, "whose retrospections extend over half a century, may naturally be expected to revert to the past." . . . "If our retrospections extend over half a century it is worth while to inquire, How will the present appear in a retrospective view at the end of the next fifty years?" From such a mountain of observation he looked forward as well as backward, and predicted that the history of medicine will have a steady acceleration in progress; that knowledge with reference to anatomy, histology, and

[1] Medicine in the Future, by Austin Flint, Sr., M.D. Published by D. Appleton & Co[illegible].

chemistry will advance; that our senses will be aided and augmented; that hearing will be vastly improved by means of microphonic stethoscopes; that a judicious blood-letting will be revived, and the lancet will again find a place which it lost through over-use; that bacterial etiology will be established and revolutionize the treatment of certain diseases; that the little understood functions of spleen and liver, the thyroid body, the lymphatic glands, the supra-renal capsules offer problems which will form "a vast and fruitful field for future clinical researches."

The paper closes with a word in regard to the medical press, the teachings of text-books and colleges, and the physician of the future is referred to with pleasantry, and that gentleman is gently admonished that if he specializes too much he may bring about a professional demoralization.

The delightfully expressed optimistic views would greatly cheer one inclined to regard the future of medicine gloomily; but there are few such. It is none the less pleasant to have hopes confirmed by a horoscope so skilfully cast.

THE SUPERFICIAL AREA OF THE AIR-CELLS.

THE respiratory organs of mammals present a remarkable example of nature's skill in adapting a mechanism to a special use. The animal system, above all things, must absorb oxygen and must do it very actively. Every day about twelve thousand quarts of air must be laboriously sucked into the human lungs in order to furnish the tissue with its indispensable gas. Nature kindly provides that this be done automatically with very little conscious effort. In order to allow opportunity for the oxygen and blood to mingle, the lungs are made practically to consist of an enormous superficial area of thin, flattened cells with an extremely rich plexus of blood-vessels on the under surface. The total number of pulmonary air-cells has been estimated to be one thousand seven hundred millions, and the actual surface they present to the inhaled air was estimated by Kuess to be two hundred square meters. Recently, Marc See (*Bulletin de l'Acad. de Méd.*) has reported estimates which give a different result. The total area, he says, is about fifty four times that of the cutaneous surface of the body, or eighty-one square meters. The plexus of vessels on the other side of this surface is so rich as to form almost a completely closed surface of blood, the total area being about one-fourth less than that of the epithelial surface. By a peculiar arrangement the blood in these capillaries travels more rapidly than in the systemic capillaries, and is less subject to variations due to nervous influence. The whole blood of the body surges through these passages three times every minute, and in the twenty-four hours about twenty thousand litres of blood are passed through the respiratory organs and brought in contact with the air.

THE EDITOR OF THE BRITISH MEDICAL JOURNAL, Mr. Ernest Hart, was urgently pressed to contest a seat for Parliament as a Gladstonian Liberal. We regret to learn that his health was such that he was positively forbidden to undertake the contest.

News of the Week.

DR. DANIEL LEWIS.—At the Semi-centennial Commencement of the Alfred University, New York, the degree of Ph.D. was conferred on our distinguished townsman, Dr. Daniel Lewis.

COCAINE IN GYNECOLOGY.—By some oversight the proof of Dr. Johnston's article did not reach him in time, and consequently he lost the opportunity of making some corrections in the same.

MORE ABOUT THE SWINDLING "DOCTOR."—We have received several letters from prominent medical men in this city complaining that they have been duped by the swindler who was exposed in our issue of July 10th. They have, however, only themselves to blame. The moral is, "Never trust a stranger when he wants to borrow money." Any man away from home can get money by telegraphing to his friends there. The law of accidents usually provides against the simultaneously disastrous concatenation of circumstances of "a sick wife, starving child, unpaid board, the cashing of a check after banking hours, and the hurry to catch the last train homeward!"

UNWISE FRIENDS often do a cause more harm than violent enemies. What could be more foolish than the following remarks of one Dr. Anna Kingsford: Dr. Kingsford "proceeded to give her reasons for thinking that the work of M. Pasteur would eventually give the death-blow to vaccination, and open the eyes of the people of Europe to this abominable theory of attempting to cure disease by means of disease. So far from supporting vaccination by his theory, M. Pasteur was doing his utmost to put an end to it, and for that, though he knew it not, she thanked him."

DR. THOMAS R. FRENCH, of Brooklyn, has been appointed to the full Professorship of Laryngology in the Long Island College Hospital.

THE AMERICAN RHINOLOGICAL ASSOCIATION will hold its fourth annual meeting at St. Louis, Mo., on October 6th next.

MEETINGS OF NATIONAL ASSOCIATIONS.—During the past week the American Neurological Association held its annual meeting at Long Branch, and the American Ophthalmological and Otological Associations met at New London.

DR. JOHN C. DALTON received the degree of LL.D. from Princeton College at its last commencement.

A NIGHT PHARMACEUTICAL SERVICE.—The Municipal Council of Paris has established a night pharmaceutical service. Poor patients after applying to the police station for a night-service doctor get a prescription and go to a night service druggist.

FAILURE OF HYPNOTISM IN LABOR.—Dr. Porak (*Nouv. Arch. d'Obst. and Gyn.*) reports another case in which a hysterical woman was hypnotized at intervals during her labor. In the later stages, however, when the pains became very severe, it was found impossible to put her in a hypnotic sleep.

Surgeon-General Robert Murray, of the United States Army, will be sixty-two years of age in August of the present year, when he will be placed on the retired list.

A Postgraduate School is to be organized in Edinburgh, and another, possibly, in Glasgow.

Sims Memorial Fund.—The following additional subscriptions have been received since our last acknowledgment: Æsculapian Society of the Wabash Valley, Ill., $20; R. Ludlam, M.D., Chicago, Ill., $10; D. S. Smith, M.D., Chicago, Ill., $10; Central Kentucky Medical Association, $5; J. S. Crane, M.D., New York, $5.

Perhaps a New Disease?—A daily paper announces the death of G—— S—— from "acute thesis."

Improvident Medical Men.—Our London correspondent, in speaking of the approaching jubilee banquet of the "British Medical Benevolent Fund," draws attention to the lamentable lack of providence exhibited by too many medical men. The warning is needed. The poor parish doctor who dies and leaves his family destitute is to be pitied. But what shall be said of eminent men in consulting practice who do the same? Yet, within the last few years, two distinguished London physicians have done so. They both lived at the West End and kept up expensive establishments, of which, at their decease, their widows were only too glad to dispose. Their families were, to say the least, left very badly off, and in one case a fund was started for their benefit. Neither of these physicians could perhaps have anticipated his untimely death, as both were men of good physique and robust health, and both had only attained early middle age.

One of the best known medical benevolent organizations is the "British Medical Benevolent Fund," which has for its president the late President of the Royal College of Physicians, Sir George Burrows, Bart. It is just completing its fiftieth year. It affords pecuniary relief to distressed medical men, and their widows or orphans. It also grants annuities to the aged or disabled among them. The extent of its operations may be judged of from the fact that in these various ways it disburses annually about £3,000.

Another very useful body is the "Society for the Relief of Widows and Orphans of Medical Men." Sir George Burrows is also the president of this society. Unlike the "British Medical Benevolent Fund," its benefits are restricted to its own subscribers. It is at once a provident and a benevolent society. Subscribers of two guineas a year are eligible for election as members, and having become such the continuance of this small yearly subscription entitles their families to participate in the benefits of the society at their death, should they unfortunately be left needy. It differs from a system of assurance because the benefits of the society are only conferred upon the indigent. The annual sum distributed is nearly as great as that paid away by the "British Medical Benevolent Fund." The society was founded in 1788, and is thus approaching its centenary. Since its foundation it has distributed a sum considerably over £100,000.

No inconsiderable amount of benevolence is also exercised by the "Royal Medical Benevolent College, Epsom." This was founded in 1831. It provides an asylum and pensions for duly qualified medical men (and their widows) who are in reduced circumstances, and a school for the sons of medical men. There are fifty pensioners, each of whom receives £21 a year. Pensioners must be medical men (or their widows), who are not less than sixty years of age, and whose annual income does not exceed £60. Of the fifty pensioners, twenty-four are resident, and each one is provided with three furnished rooms and an allowance of coal; the rest are non-resident. The school receives fifty foundation scholars, the sons of medical men, who are educated and entirely maintained at the cost of the institution. One hundred and seventy paying scholars are also received. The school is an excellent one, and the science teaching especially good. Many of the science "scholars" and "exhibitioners" at the various hospitals come from Epsom College, and owe much of their success to the careful instruction there received. The annual meeting of this excellent institution was held last week, and was presided over by Sir Joseph Fayrer, who spoke warmly in favor of the institution. Sir Joseph Fayrer is a distinguished retired Indian medical officer. His name will be imperishably associated with the history of the Indian Mutiny, he having been Residency Surgeon at Lucknow during the siege.

Reports of Societies.

THE AMERICAN OTOLOGICAL SOCIETY.

Nineteenth Annual Meeting, held at the Pequot House, New London, Conn., July 20, 1886.

The Society was called to order by the President, Dr. J. S. Prout, of Brooklyn.

Dr. S. Sexton, of New York, read the first paper, which was entitled

ACUTE AND CHRONIC PURULENT INFLAMMATIONS OF THE MIDDLE-EAR TRACT AND THEIR COMPLICATIONS.

It was based on the records of over two thousand cases, which were divisible into three classes: acute purulent inflammation of the middle-ear, acute catarrhal inflammation of the middle-ear, and chronic purulent inflammation. The consideration of acute catarrhal inflammation was included in that of acute purulent inflammation, since in the beginning the conditions were probably the same, although not always going on to suppuration. Out of this series of cases one hundred and thirty-one were selected on account of their gravity. Of this number there were twelve deaths.

In no disease is a knowledge of regional anatomy more important than in those of the middle-ear.

He then gave a *résumé* of the anatomy of the temporal bone.

The symptoms were next referred to. Brain symptoms, such as headache, vertigo, pain, delirium, nausea, and vomiting may occur in consequence of middle-ear disease without lesion of the cerebral structure.

The prognosis of purulent inflammation of the middle-ear is favorable when suitable treatment is adopted, both as regards life and the preservation of hearing. Out of twenty thousand cases of ear disease, where the patient has been seen at the beginning of the attack, no fatal case has occurred.

In regard to treatment the speaker recommended incision of the drum-head. [illegible] of the mastoid

process has been recommended by some authorities. Dr. Sexton took up a consideration of the indications which have been regarded as calling for the application of the trephine, and held that they were insufficient. From his experience he was led to believe that drainage could be best maintained through the natural channel.

The speaker also described

A NEW OPERATION FOR THE RADICAL CURE OF CHRONIC PURULENT INFLAMMATION OF THE MIDDLE-EAR TRACT.

Since describing a form of chronic purulent inflammation of the attic, in a paper read before the Society last year, it had occurred to him that something might be done with these cases by means of an operation. It seems especially desirable to cure these cases when the ear remains simply a reservoir for purulent matter liable at all times to infect the system. It is found that in the greater number of these cases the remaining portion of the conducting mechanism no longer serves to aid in the transmission of sound, but acts rather as an obstruction to drainage. Where the membrana flaccida and a portion of the ossicular chain only remain, the former often becomes thickened and everted, forming with the altered mucous membrane a pouch for the retention of putrescent matters which may slowly escape. Where granulation tissue or polypoid growths are present in the attic or antrum, the escape of secretions is still further interfered with. This produces long-continued and great irritation.

The author had observed that in a number of cases where the transmitting mechanism had been lost a spontaneous cure followed, and it occurred to him that the curative action of nature might be imitated with advantage. Where drainage from the attic and antrum is interrupted, a cure can only be assured by an operation permanently clearing the passage outward from the tympanum.

Last year the operation was tried on a long-standing case of otorrhœa due to chronic purulent inflammation of the attic. In order to avoid the danger of using an ordinary lamp in connection with the administration of ether, an electric light was used. The operation has since then been fully performed in several cases.

The first step of the procedure is to separate the membrana flaccida from the edge of the auditory plate and to remove any portion of the membrana vibrans adherent to the auditory ring. If the malleus and incus remain *in situ* it is well to divide the tendon of the tensor tympani muscle, when present, where it leaves the handle just behind the short process and below the chorda tympani. The chorda tympani when remaining is then divided where it enters the tympanum at the pyramid and also at its exit into the canal of Huguier. The long process of the malleus, being also received into the glenoid fissure by means of this short oblique canal, along with the chorda, may be more or less detached at the same time. The detached tissues and ossicles should now be removed with the forceps. It will frequently be found that the incus, having been displaced, still remains. It may be removed with the attic scraper, which is to be introduced from below and passed up along the inner wall of the tympanum, when the distal extremity may be carried over the incus or malleus, if the latter bone remains, and by traction the ossicles can be detached. Polypoid masses, granulation tissue, and the products of inflammation may now be removed with the cutting curette or cutting forceps, and the parts dressed with a four per cent. solution of cocaine to relieve pain. There is usually free bleeding during the operation, often sufficient to protract it and increase its difficulties.

The effect of injury or destruction of the chorda tympani nearly always manifests itself in some way, but had never in his experience been a matter of serious import. Disturbances of taste sometimes follow the operation, but they gradually disappear and leave the sense of taste unaffected.

The drum should be kept well cleansed, and light dressings of boracic acid applied until healing takes place. The salicylic acid powder may be applied as freely as can be borne. In some cases this is irritating at first, but tolerance is soon established. It may, then, be kept up until the parts cease to discharge.

In the cure resulting from this treatment, a dermic transformation of the tympanum takes place, but mucus may occasionally gain admission from the Eustachian tube during recurrent head catarrh or on blowing the nose. This should be frequently removed with cotton-wool, and, if necessary, the drying applications renewed for a time.

Where the incuso-stapedial connection remained he would not hesitate to perform this operation, unless a very considerable portion of the membrana vibrans was present.

The instruments employed, and some of the diseased ossicles removed, were exhibited. A number of photographs were shown.

DR. AGNEW thought that, where the inflammation involves the mastoid cells, some portion of the external wall of the mastoid should be removed. The trephine does not expose a sufficient area of the cancellated tissue of the mastoid. He did not see how the new operation which had been described would be of service in these cases.

DR. SEXTON remarked that the new operation was recommended only in chronic cases.

DR. H. KNAPP, of New York, said the upper tympanic pneumatic cells resemble to a certain degree the frontal sinuses. These have a direct natural drainage through the infundibulum into the nose. When this is closed by disease, the lateral part of the sinus over the orbit dilates, and the cavity is more easily reached, and more effective drainage is obtained by opening the sinus from the orbit. In a like manner we obtain in most cases easier and more effective drainage of the supra-tympanic cells by opening the mastoid cells with which they communicate.

The next paper was by DR. A. H. BUCK, of New York, on

PAINLESS AND ONLY SLIGHTLY PAINFUL ULCERATION OF THE MEMBRANA TYMPANI, PROBABLY OF A TUBERCULAR NATURE.

The speaker stated that the recognition of the early stages of tubercular disease of the drum-membrane was important, and the object of the paper was to call attention to the features by which this could be recognized. Three cases had been seen by the author, and were described.

Tinnitus and slight impairment of hearing were the first symptoms noticed. In two of the cases, which were examined at an early period, there was slight redness and swelling at the upper part of the membrana tympani and of the skin covering the bony wall. In a short time the infiltration extended into the entire posterior superior quadrant. The membrane became bulging, and at the most prominent point a perforation established itself.

In the incipient stage the distinguishing features are the tendency to localization in the upper posterior portion of the membrana tympani, the marked insignificance of the pain or even its entire absence, and the intolerance to all but the simplest local measures.

DR. SEXTON stated that he had seen many cases of catarrhal inflammation of the middle ear in phthisical subjects. The tendency of the structures of the ear to break down in advanced phthisis is very great.

DR. E. GRUENING, of New York, had seen a number of cases in which he was led to infer that the ulceration of the drum-head was due to tuberculosis. In one case, that of a young man, only one ear was affected. There was very little purulent discharge. There were two openings showing that this was not the result of perforation from accumulation. It appeared to be a melting down process. In another case, there were multiple openings.

These were in the membrana tympani proper. These cases improved under treatment, but the openings remained.

Dr. C. R. Agnew had seen a number of cases in which he considered the origin tuberculosis. In a considerable number of these cases the main lesion has been in the drum-head below the extremity of the handle of the malleus. He described the case of a young man who had phthisis at the apices of both lungs, and who, after a short period of tinnitus, found that he whistled through his ear. In the ear complained of an opening, looking as though it had been removed by a punch, was found. Within a few days the same thing occurred in the other ear.

Dr. J. A. Andrews, of New York, had examined a large number of cases, and some with a great deal of care, but had never found the bacillus. Twice in cases of advanced tuberculosis he had seen, on examining the drum-membrane, little white, glistening points, about the size of a pin-head, not secreting at all, and in one case with no congestion. In both cases the spots disappeared in a few days, and within twenty-four hours there was a little, clean punched-out opening in the drum-membrane. This occurred without any discharge. It seemed to him that he was dealing with isolated tubercles in the tissue of the drum-membrane. One of these cases died a few months later from the general disease.

Certain Technical Details Relating to Operations on the Mastoid Process.

Dr. A. H. Buck, of New York, read a paper with the above title. He referred to the objections which had been made to the drill. It has been stated that there is danger of plunging the drill into the lateral sinus or even into the brain. He had, however, found no tendency for the drill to go astray. It had been said that the opening made was too small, but any sized drill might be made. He used a drill one-fourth of an inch in diameter until the antrum was reached, and finished the operation with a smaller drill. This gives a sufficient opening for drainage. Where there is a large sequestrum it is necessary to make a larger opening.

After the use of the drill pyæmia and septic fever are rare. With a knowledge of the part to be operated upon the drill may be used with perfect safety. It can be guided perfectly by resting the fingers on the bone. The conical shape of the drill also enables the operator to tell when its point has entered a cavity.

The objections to the use of the chisel were next taken up. When this is used the wound in the adjacent soft parts must be larger, and the opening in the bone is more extensive, leading to a depressed cicatrix. More time is required in the operation, and it is not free from danger. These objections are, however, trifling, if the results of the operation are found to be more satisfactory than those following the use of the drill. A study of the statistics of both methods seems to show that there is nothing to warrant the statement that chisels and gouges are to be greatly preferred to drills in establishing openings into the mastoid process.

In operating with the drill, after making the opening, he cuts out a little canal for the escape of the discharges, for the opening made by the drill is covered by the flap when it comes into position. For the first four or five days after the operation the wound is irrigated once a day with a bichloride solution, 1 to 2,000.

Dr. Buck said that in his earlier operations, he applied the drill a short distance in front of the vertical line. His present plan is different. A straight vertical incision, three inches long, is made; by this means he exposed the mastoid process where it curves into the meatus. The drill is then applied to the first flat surface. The only difficulty is in establishing the final communication between the canal and the antrum.

Dr. J. Orne Green advocated the use of the drill. He makes a small opening at first, and [illegible] what he finds. Some cases require a large opening, and in such cases the gouge and chisel will come into play. The dental engine is very applicable in some of these cases. He uses a modification of the engine, which may be screwed to a table, it is turned by a handle, and no skill is required, as in the engine worked with the treadle. Used in this way, I have found the engine of great service. The burrs can be used with the greatest delicacy.

Dr. H. Knapp, of New York, favored the use of the chisel. In his first operations he used a drill, but had abandoned it. With the chisel you can at every step observe the condition of the tissue which you are cutting, and you have a perfectly smooth surface, rendering it easier to cleanse the wound. It is also very easy to manage the chisel.

Dr. H. D. Noyes, of New York, thought that there was much less danger in the use of the chisel than of the drill. There is often great differences in the anatomical relations of the parts. The lateral sinus is not always found in the same place. With the drill there is danger of perforating the wall of the sinus or of some important vein. With the chisel or the gouge you explore the part layer by layer, and ascertain how the parts are situated. This is a strong argument in favor of this instrument.

Dr. J. A. Andrews, of New York, believed that the chisel is the better instrument and can be used with more caution than the drill. He believes that a collection of pus should always be given free vent, and therefore makes a large opening.

Dr. E. Gruening, of New York, had formerly used the drill, and in acute cases the results were all that could be desired. The drill was, however, not applicable to all cases, and he had since used the chisel. A small opening may be made with the chisel. What can be done with the drill can be done with the chisel.

Dr. A. H. Buck, of New York, in closing the discussion, said he was not in antagonism with the chisel in those cases where a large portion of bone is to be removed. He left those out of consideration in his paper. Where a large mass is to be removed, it can not be removed with the drill. The two instruments cannot come into conflict.

A communication with reference to the organization of a

Congress of American Physicians and Surgeons.

was presented and referred to a committee consisting of Dr. C. R. Agnew, Dr. J. H. Knapp, and Dr. John Green, to consider and report at the evening session.

The Morning Session was then adjourned.

Evening Session.

The first paper was on a

Fatal Termination of a Case of Sclerosing Mastoiditis after Chiselling of the Bone,

by Dr. H. Knapp, of New York.

A man, aged fifty, had extensive suppuration in both ears after scarlet fever in childhood. The right ear became totally deaf and the left, very hard of hearing, became deaf (hearing reduced to a quantitative perception of sound) by a recent attack of dizziness. Dr. Knapp found both tympanic membranes absent, the cavities sclerosed in both, pale in the right but congested in the left ear. Behind the left ear was found a cavity fully an inch deep, lined with immovable skin, the result of former exfoliation of bone. Three weeks later facial paralysis on the left side occurred. It disappeared in two weeks under steaming and large doses of iodide of potassium. Two weeks later, the patient suffered with constant intense headache and nausea. The mastoid was opened to the depth of half an inch by chiselling. The bone was

compact and in the depth very vascular. During the first two days the patient was sleepy, could not be aroused on the third, and died comatose on the fifth. No autopsy was allowed. Death was due to traumatic meningitis.

In regard to opening the bone in sclerosing mastoiditis, the prognosis is good when the sclerosis is the result of catarrhal or plastic inflammation, but bad when it is the consequence of old caries or necrosis. There are cases on the border line, and even when the prognosis is bad, the indications may be strong. The operation will rescue a certain number of the otherwise fatal cases.

Dr. O. D. Pomeroy, of New York, read a paper on

A CASE OF ABSCESS OF THE MASTOID CELLS WHERE THE CHIEF INDICATION FOR OPERATION WAS ELEVATION OF TEMPERATURE.

A. S——, aged twenty, fairly robust, had a violent attack of otitis of the right ear, which came on January 30, 1886. The following morning there was free discharge. On February 1st he entered the hospital, when a large perforation was found; a poultice and warm douches were ordered. By February 4th the membrane looked almost normal. There was some pain in the occiput and a temperature of 103.6° F. Ten grains of quinine with twenty grains of iodide of potassium, to be repeated in three hours, was ordered. This was followed by a reduction of two degrees in the temperature. The following day the temperature again went up, and it was apparent that a purulent process was going on. There was no swelling over the mastoid, and the pain was no greater than might be expected from a neuralgic condition.

After consultation it was decided to open the mastoid process. A drill was introduced, and from four to six drops of pus evacuated. After the operation the patient continued to improve until he was discharged cured.

Dr. Charles H. Burnett, of Philadelphia, gave the following account of

TWO CASES OF CHRONIC PURULENT INFLAMMATION OF THE ATTIC OF THE TYMPANUM, WITH PERFORATION OF THE MEMBRANA FLACCIDA, TREATED WITH PEROXIDE OF HYDROGEN.

In the first case no application had had the same good effect as the peroxide of hydrogen. Every other medicament had seemed to irritate rather than heal the inflamed mucous membrane. In the second case the discharge, which had been very chronic, was promptly checked by the use of the peroxide of hydrogen.

The chemical formula of this drug is H_2O_2, and by its affinity for albuminous matters, especially those of pus, it seeks every particle of this matter in a cavity like the middle ear, and thoroughly cleans the parts. The union with pus is shown by a copious foam, which boils out of the external ear. When the foaming ceases and the peroxide returns clear the diseased cavity has been thoroughly cleansed. In many cases this seems sufficient to effect a cure. Where there is a perforation in the membrana flaccida, the application is made by means of the tympanic syringe, the long and slender nozzle of which is introduced through the perforation at the attic of the tympanum. The peroxide is used undiluted.

A paper with the following title,

IN THE PHYSIOLOGY OF HEARING IS THERE AN OVERLAPPING OF EACH AUDITORY FIELD, THE SAME AS IN BINOCULAR VISION?

was read by Dr. William S. Little, of Philadelphia.

Cases of one-sided deafness afford the opportunity of mapping out the auditory field for one ear, and it is found, with the watch at two feet from the ear, the tick can be heard about ten or fifteen degrees across the median line of the head. This gives more scope to hear sounds produced on the side of the head opposite the good ear. The tuning-fork is not heard even up to the median line on the side of the ear tested. The watch has been used in making the observations. If the field of one ear reaches beyond the median line to about ten degrees, we have, when both ears are normal, an overlapping of each field to the extent of fully ten degrees on either side of the median line in front, above, and behind the head. Each ear hears sounds in this area of twenty degrees, outside of this area each ear hears singly. By means of this there is no need to turn each ear toward the source of sounds which reach the individual; the direction of sound is best found in this way for safety in walking and maintaining the erect position. Sudden loss of hearing on one side puts the sufferer to great annoyance, as the ability to determine the direction of sounds is in a measure lost, the patient often looking in the wrong place when called. It is fully as perplexing, if not more so, than in a case of sudden loss of sight in one eye, making seeing dependent on one organ of vision.

The attempt to restore hearing should be directed not only to obtain hearing in a line directly in front of the ear, but also to increase the area of hearing in the affected ear or in both affected ears, till it reaches, if possible, the coalescence seen in normal ears.

The literature of the subject of acoution and otology does not give any information on this point; too close a comparison between the eye and the ear cannot be made. The auditory and optic nerves respond to very different media. The auditory nerve has no commissure or decussation of fibres like the optic, and has a less central position in the cerebrum than the auditory.

A paper on "Two Cases of Ear Disease Due to Traumatism," by Dr. Gorham Bacon, of New York, was read by title.

The Society then went into Executive Session.

The proposition with reference to the organization of a Congress of American Physicians and Surgeons was discussed, and a committee of conference was appointed, consisting of Drs. C. R. Agnew, New York; H. Knapp, New York; John Green, St. Louis; W. H. Carmalt, New Haven; and George Strawbridge, Philadelphia.

The officers for the ensuing year are as follows:

President—Dr. J. S. Prout, of Brooklyn.

Vice-President—Dr. Samuel Sexton, of New York.

Secretary and Treasurer—Dr. J. J. B. Vermyne, New Bedford, Mass.

Committee on Membership—Drs. Gorham Bacon, W. S. Little, and E. W. Bartlett.

The following were

ELECTED TO MEMBERSHIP:

Dr. J. B. Emerson, of New York; Dr. J. O. Tansley, of New York; Dr. J. L. Minor, of New York; Dr. Henry L. Morse, of Boston; Dr. Huntington Richards, of New York; and Dr. T. Y. Sutphen, of Newark, N. J.

The Society then adjourned.

Pasteur's Record.—M. Graucher, Pasteur's assistant, in a recent lecture, said: "Of 1,335 persons who were inoculated to June 21st, he found that of 96 patients who belonged to the first or experimental category—namely, of those in whom the existence of rabies was indisputable—there was only one death, or a mortality of 1.04 per 100, or, in round numbers, 10 per 1,000; and of 644 persons of the second or clinical category, 3 succumbed to rabies, or 0.46 per 100 of the mortality, or 5 per 1,000 in round numbers. In comparing these statistics with those of the department of the Seine, it will be seen that the average mortality from hydrophobia has been reduced from 160 per 1,000 to 7.5 per 1,000. These figures apply only to those bitten by mad dogs. As regards the 48 persons bitten by mad wolves before April 22d, there were 4 deaths; but a calculation based upon eight documents communicated to M. Pasteur indicates a mortality of 82 per 100 after the bites of mad wolves. A paper published by Professor Brouardel, in the 'Dictionnaire Encyclopédique des Sciences Médicales,' on rabies, gives a mortality proportion of 67 per 100. Thus it may be seen that the difference between the two results is considerable."

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 12, 1886.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

DR. WALTER MENDELSON presented a specimen of

LARGE RETRO-PERITONEAL SARCOMA, WITH SECONDARY DEPOSITS IN THE KIDNEYS AND LIVER.

I. S——, aged fifty-seven years, merchant, single, German. One sister died of cancer. Family history otherwise good. Habits temperate. No syphilis, rheumatism, or gout. Had always enjoyed good health until present illness, for which he consulted me first on February 15, 1886. He then complained of great constipation, almost complete anorexia, insomnia, and very great lassitude and weakness. From his friends Dr. M. learned, later, that for the past two or three months he had been observed to have emaciated and run down generally.

Remedies to relieve the anorexia and constipation were prescribed, and a few days later the patient's urine was examined and was found to contain a trace of albumen and a few hyaline, finely granular, and wavy casts. The quantity passed was, if anything, a little less than normal, and contained three per cent. of urea.

Physical examination of the heart, lungs, and liver gave negative results, and as no abdominal pain or discomfort was complained of, the abdomen received only a cursory examination.

The patient's urine had been analyzed a year previous and found normal.

In view of the results of the present analysis a diagnosis of chronic or subacute diffuse nephritis was made, and treatment of the symptoms on that basis was pursued, under which the patient's general condition improved slightly.

On March 10th microscopical examination of the urinary sediment showed for the first time a large number of red blood-corpuscles. They were neither discolored nor deformed, as blood coming from the kidney is apt to be, and it was thought at the time that a hemorrhage in the urinary passages themselves had occurred, although there was no history of pain, such as the passage of a calculus would produce.

On March 14th the patient first complained of pain over the right ilium, and said that for the past three days he had passed urine "the color of porter." Examination showed considerable cutaneous dysæsthesia at the location just indicated, but no pain on deep pressure. Percussion revealed an ill-defined area of dulness, and deep palpation was met by a marked sense of resistance, but no well-defined tumor could be felt.

As the patient's general strength had been steadily declining he was advised to go to bed, and in the afternoon a specimen of urine for examination was obtained. It was of an opaque, light-reddish-chocolate color, acid, of a specific gravity of 1.022, and contained a large amount of albumen. The sediment consisted of amorphous urates, mingled with great quantities of red blood-corpuscles, all of which were discolored and most of them misshapen. There were also numerous blood-casts, and casts containing rounded masses of a granular, dark-red material, which he took to be free hæmatin resulting from the decomposition of the hæmoglobin of the red corpuscles. There was also much of this material floating free in the urine.

Malignant disease of the kidney being suspected, and the patient feeling very weak, rest in bed was ordered, and on the following day Dr. William H. Draper saw the case in consultation with him. In addition to the ill-defined tumor on the left side, a mass could be felt in the right lumbar region. It was hard, indistinctly movable, and about the shape and size of a kidney, projecting as far forward as the axillary line. Manipulation caused no pain. At the time this mass was thought to be the kidney itself, either enlarged, or displaced by some growth.

A few days later Dr. Sands saw the case, and agreed with the diagnosis of malignant renal tumor which had been made, but advised against any operative interference—very wisely, as the sequel showed.

During the next ten days little change occurred. At first a good deal of dark blood was passed; the urine then became entirely clear again. Although constantly examined, no epithelial elements referable to a neoplasm could be discovered in it.

On March 24th blood suddenly reappeared again in the urine. The hemorrhage must have been very considerable, for long, bright-red clots, eighteen inches and more in length, and about the diameter of a goose-quill, were passed very frequently. They would present themselves at the meatus, and could then be pulled out without breaking.

The question arose: Whence this sudden hemorrhage? At first it seemed, from the length and diameter of the clots, as though they were formed in the ureters, but later he concluded that secondary deposits had occurred in the bladder (though rectal examination proved negative) giving rise to the hemorrhage. The clots, he conceived, were formed by the contracting bladder forcing the jelly-like coagulum collected at its fundus through the urethra, thus moulding the clot into shape, just as lead-pipe is made by forcing the semi-fluid metal by hydraulic pressure through a suitable opening.

As long as the coagulum was only of jelly-like consistency the patient had but little trouble in emptying his bladder, and suffered no pain. As soon, however, as it grew firm, urination became exceedingly painful. Violent tenesmus occurred, and during the act of straining small, firm, grayish-red clots would be expelled with great force, each followed by a gush of urine. Sometimes a change of position was sufficient to cause an occluding mass to roll away, leaving the entrance to the urethra free. The clotted masses expelled were quite firm and partly discolored, being made up often of two or more layers of different colors, from blood deposited at different times. The urine was not ammoniacal. Washing out the bladder had finally to be resorted to, which was rendered rather difficult as, owing to an old stricture, a No. 9 American catheter was the largest that could be introduced. Although antiseptic precautions were used—a solution of mercuric bichloride, 1 to 6,000, was used for injecting—the urine became faintly ammoniacal; a condition, however, which passed away spontaneously when the catheter was no longer necessary, owing to all the old clots having been washed away and no new ones forming.

At this time Dr. L. B. Bangs saw the patient in consultation with him.

On March 30th clear urine was passed again, and the urine remained more or less clear until April 10th, when not more than a drachm was passed during the day. In it were found, for the first time, numerous large, round, and tailed epithelial cells, presumably from some neoplasm. At the same time not the slightest desire to urinate nor feeling of fulness in the bladder existed.

As he could pass a catheter only with difficulty, owing to the tightness of the stricture, he again requested the services of Dr. Bangs, who conclusively demonstrated that the anuria was one of suppression and not retention—at least as far as the bladder was concerned—by injecting water into the bladder and observing that all that went in flowed out again. He found the capacity reduced to from two to three ounces. The patient showed no signs of uræmia, but, on the contrary, seemed at this time brighter than usual.

This condition of anuria lasted until his death, which occurred five days later, during which time not more than about four ounces of dark, bloody urine was passed,

containing many of the large nucleated, granular epithelial cells noted before. All sorts of measures for stimulating the kidneys to action were in the meanwhile tried, since at the time it was thought that the suppression was a functional and not a mechanical one, as autopsy showed it to be.

Already, on the day following the beginning of the anuria, the patient began to complain of great itching of the skin. On the third day he was, at times, a little flighty in his mind, and inclined to doze a great deal; and when awake was very apathetic. Twitching of the limbs also set in and soon became very marked, both during waking and sleeping. By the fourth day following, the apathy had greatly increased and the patient lay with mouth partly open, eyeballs fixed and staring, and limbs twitching in a semi-conscious state; and yet at no time—even up to within an hour of his death—did he absolutely lose consciousness, for on being roused he recognized his friends and seemed perfectly aware of his approaching end.

Autopsy was performed seventeen hours after death. Rigor mortis moderate; emaciation not marked; color of skin yellowish; slight œdema of skin of back. Head was not examined. Heart normal. Lungs showed hepatization from hypostatic congestion to the depth of about one inch on posterior aspects; slight general œdema; small quantity of fluid in each pleural cavity. Abdomen: fat of omentum very yellow. Intestines distended with gas; much fat in mesentery; no enlargement of mesenteric glands. Stomach greatly distended; otherwise normal. Liver not enlarged; contained about half a dozen yellowish-white nodules, varying from size of a pea to a hickory-nut; gall-bladder full. Spleen large, but shrivelled-looking; otherwise normal.

Behind the peritoneum lay a huge cushion-shaped tumor, extending above to within three inches of the diaphragm, below to the brim of the pelvis, and on either side as far as the outer borders of the kidneys. Over the vertebral column this mass was about four inches in thickness, and completely enveloped the aorta (which was very atheromatous) and other large vessels. The surface of this mass was nodulated, and, on cutting into it, several places were found where softening had occurred. He estimated its weight to have been about six to eight pounds.

The kidneys lay partly imbedded in the tumor. Right kidney: On section, bloody urine gushed out with much force as soon as the pelvis was reached, and the ureter was found plugged by a grayish-red coagulum. The pelvis and calices were much dilated and filled with bloody, grumous masses. The parenchyma was thinned, the cortex pale, and in the papillæ there were numerous hemorrhagic, softened, and broken-down areas—evidently degenerated secondary deposits. Left kidney: Same as the right, except that in the upper portion there was a firm white nodule the size of a small pea. The pelvis and calices were dilated, and contained some clear urine. The kidney was removed, together with a large mass of the neoplasm in which it lay imbedded, and on cutting through this mass the ureter was severed, as became evident by a sudden spurt of clear urine, showing that compression of the ureter by the tumor had occurred lower down. The bladder was empty, and was the seat of no pathological alterations.

Microscopical examination of the new growth showed it to consist of a round and spindle-celled sarcoma. The sarcomatous growth had invaded the outer and middle coats of the aorta. The kidneys were in a condition of diffuse nephritis.

The case seemed to present to him the following special points of interest: Large size of the tumor, together with its rapid growth. Confirmation of the original diagnosis by examination of the urinary sediment. Occurrence of what seemed to be suppression of urine, but which was in reality retention, caused by bilateral occlusion of the ureters, from two separate causes, however—the right being plugged by a coagulum, the left being closed by pressure. It might also be noted that, with the exception of the liver and kidneys, the sarcomatous growth was limited to the retroperitoneal lymph-nodes. Not even the mesenteric nodes—as far as could be ascertained—though lying in such close proximity, were involved; a circumstance which might be explained by the fact that the general course of the lymph-current here is in a direction away from the mesenteric toward the retroperitoneal nodes.

Dr. Prudden remarked that retroperitoneal tumors were interesting because of the difficulty in classifying them, as it was not always easy to say whether a given specimen should be called sarcoma or carcinoma. He asked Dr. Mendelson as to the condition of the wall of the abdominal aorta.

Dr. Mendelson said that the adventitia and the media were involved, but the intima was unaffected. In the other case mentioned the neoplasm had entered the lumen of the vein, but there was no evidence of metastatic tumors.

DILATATION AND FATTY DEGENERATION OF THE HEART—BLOOD-CHANGES OF PERNICIOUS MALARIAL FEVER.

Dr. Putnam-Jacobi presented the heart removed from the body of a child, aged five years, who died at the infirmary. The child had been living in a state of great poverty, and the visiting-physician was called to see it on account of a very severe epistaxis. The child when first visited was completely exsanguinated. It was also stated that he had been perfectly well up to two years ago, when he had measles, and from that time on he had not been very well. At three years of age he had scarlet fever, and a few months afterward he had a profuse epistaxis, one which was almost as exhausting as the last, and between these attacks there had been several mild bleedings from the nose. The pulse was 150, and the temperature 101° F. in the rectum. There was evidence also of marked dilatation of the heart, the apex beating at a finger's breadth to the left of the nipple line, and there was a distinct systolic murmur with its maximum intensity at the apex. It had been supposed, and she rather accepted the diagnosis, that there was mitral insufficiency, with some dilatation of the heart in consequence, and that the epistaxis had been that which occurs sometimes with this cardiac lesion, but it was evident at the second visit that this explanation did not satisfy the case. The child did not seem to recover at all, notwithstanding it received a full supply of food and some stimulants. Dr. Jacobi then concluded, without any history of rheumatism and nothing to cause endocarditis except scarlet fever, that the dilatation had developed since the occurrence of the epistaxis, or in consequence of some cause to which the hemorrhage itself was due.

It was a question whether it might not be due to an intense form of malarial poisoning, producing a rapid alteration in the constitution of the blood, accompanied with profuse hemorrhage, as described by Italian writers. The blood was not examined.

Autopsy.—No normal fluid in the pericardium. The heart extended vertically from the first intercostal space to the lower border of the *sixth* rib, and transversely from the right border of the sternum to a line a finger's breadth beyond the left nipple line. Its transverse diameter was 10 ctm.; the left ventricle was markedly dilated; the right to a less degree. A clot extended into the vena cava almost its entire length. There was a certain amount of clot in the mitral valve, and the clot in the right ventricle extended into the pulmonary artery. The muscular tissue of the heart was extremely pale, especially over the right ventricle; that of the left was very much redder. There were broad white patches along the line of the blood-vessels, and there was a patch of fat at the apex of the heart. The endocardium of the left ventricle was streaked with yellowish-white lines, most marked

upon the septum and papillary muscles. In the right ventricle there was dilatation, but no such streaking of the endocardium. The tricuspid valves were normal. There was a very slight roughening about the base of the pulmonary valves.

The *liver* was of normal size, rather pale, and dotted with pale yellowish specks. The *kidneys* were white, the capsule non-adherent, and the lower portion the seat of hypostatic congestion. On section, white bands were found extending down from the cortex to the papillæ. On microscopical examination the nucles of the heart were found to be in the condition of partial fatty degeneration; in no section were all the fibres granular, but lying between normal fibres could be seen four or five in which the striations had disappeared entirely and had been replaced by fine granules. The nuclei of the sarcolemma were stained on the fibres which were preserved, and on some of those in which the striations were lost.

The kidneys also showed a mixture of fatty degeneration with normal tissue, some tubules showing the epithelia normal and others presenting well-marked fatty change. In both liver and kidneys the tissue was considerably infiltrated with red blood-corpuscles.

In connection with the specimens, Dr. Putnam-Jacobi exhibited illustrations of certain bodies formed in the blood, and described by Tommasi-Crudeli, in his article in the first volume of the proceedings of the last International Medical Congress, as belonging to certain forms of malarial fever. In the present case the question arose whether the affection was one of malarial poisoning, described by Crudeli, or was one of hæmophilia.

Dr. Mendelson asked if the aorta was abnormally small.

Dr. Putnam-Jacobi said that such a condition was not noticed.

Dr. Mendelson said that cases had been reported in which the blood-vessels were too small to carry sufficient blood to meet the needs of the body, and in these cases hemorrhages occurred very frequently.

Dr. Putnam-Jacobi said that those were the conditions in cases of pernicious anæmia.

Dr. Mendelson said that they had been noticed without pernicious anæmia, and he referred to the case of a tall, thin young man who was taken ill very suddenly, became unconscious, and died in about ten minutes. Post-mortem revealed hemorrhage into the brain. The aorta was found to be uncommonly small, and all the blood-vessels were proportionately small and thin.

Dr. Putnam-Jacobi said that the effect of such abnormal smallness of the blood-vessels could scarcely be felt during childhood, but it would be during adolescence, when the arteries were elongating and the tension of the arterial system was rising, that the effect of the condition alluded to would be felt first; in the little child it would scarcely have any effect.

Dr Mendelson said that he thought it might be interesting to know whether this might not be a case occurring in a child.

Dr. Prudden then exhibited, under the microscope, a section of brain-tissue which he received from Dr. Councilman, who had described certain indeterminate bodies found in cases of pernicious malarial fever.

Dr. J. Lewis Smith presented a lung with the bronchial glands, just removed from the body of an infant, eight months old, that had had a slight hacking cough for some time. There was no marked acceleration of either respiration or pulse. The temperature was, for a day or two before death, 102¼° F. The autopsy showed

ENLARGED AND CHEESY BRONCHIAL GLANDS.

It was one of those cases, therefore, which might be fairly called *bronchial phthisis*, but there was no softening of the glands. It was the condition which in infants soon terminated in general miliary tuberculosis. Dr. Smith thought that the mistake was frequently made of regarding cases in which enlarged bronchial glands obstructed free return of blood from the brain, and consequently gave rise to an effusion of serum into the ventricles, as cases of tubercular meningitis. In such cases there would be marked cerebral symptoms, but without vomiting, sighing respiration, or elevation of temperature, the condition of affairs he had seen in a case recently.

The specimen was referred to the Committee on Microscopy to be examined for the tubercle bacillus in the enlarged and cheesy bronchial glands.

The Society then went into executive session.

Correspondence.

OUR LONDON LETTER.

[From our Special Correspondent.]

THE OPHTHALMOLOGICAL SOCIETY—INTERSTITIAL KERATITIS IN ACQUIRED SYPHILIS—THE EXAMINATIONS OF THE COLLEGE OF PHYSICIANS—MEDICAL CANDIDATES FOR PARLIAMENT—THE ELECTION OF DIRECT REPRESENTATIVES ON THE MEDICAL COUNCIL—THE ELECTIONS IN THEATRES OF THE HOSPITAL OF NEW YORK

[illegible]

The concluding meeting of the Ophthalmological Society for this season was held on this day week. A number of interesting cases and drawings were exhibited. Dr. Brailey showed drawings from a case of monocular iritis in a child. He considered it to be tubercular in nature, and Mr. Hutchinson remarked that the presence of enlarged cervical glands was in favor of this view. Dr. Brailey also showed a case of interstitial keratitis, which he regarded as tubercular in origin.

Dr. M. J. Symons gave the history of a case in which changes had occurred in both corneæ of a man, aged twenty-nine, who was the subject of acquired syphilis. When he came under treatment there was thinning, bulging, and opacity over limited areas of both corneæ, without any disturbance of the epithelium. The iris was partially adherent in both eyes. The other ocular tissues appeared to be healthy. Iodide of potassium affected but slight improvement. Mr. Hutchinson observed that the corneal changes had occurred in the tertiary period, but he was not certain that they were really due to the syphilis. He asked whether any members had seen corneal changes in acquired syphilis. This inquiry elicited somewhat unexpected testimony. Mr. Nettleship, Mr. McHardy, and Mr. Lang all referred to cases they had seen of interstitial keratitis occurring in patients suffering from acquired syphilis. In one of Mr. Lang's cases the disease occurred twelve years after infection. In response to a query from Dr. Angel Money as to the latest age at which interstitial keratitis of congenital syphilitic origin could occur, Mr. Hutchinson said he had seen several cases as late as thirty-six years of age; Mr. Nettleship mentioned a case he had seen in which the patient was between thirty and forty; and Mr. Adams Frost, one in a woman thirty-nine years of age.

At the conclusion of the meeting, Mr. Hutchinson, in giving up the presidential chair, gave a short valedictory address. He referred to the satisfactory progress which had been made during the three years which have elapsed since he became president. He suggested tobacco amblyopia and amblyopia potatorum as suitable subjects for investigation. Alluding to Mr. Nettleship's case of progressive failure of sight in a woman, without any other symptoms, he asked what was the meaning of this temporary extinction of a special sense? Was it allied to the temporary blindness of megrim? The assumption that such cases were due to retro-ocular neuritis required careful investigation.

The re-election of Mr. Savory as President of the College of Surgeons has come as a surprise to most outside the Council; so has the appointment of two new vice-presidents, viz., Mr. Hutchinson and Sir Joseph Lister. The latter appointments will probably lead the way for a complete abolition of the old vicious rule of election by seniority. Mr. Savory's re-election is the more noteworthy as it is unprecedented. The Presidency of the College of Surgeons has always been an annual office, unlike that of the College of Physicians, where, although the election is annual, the term of office has usually extended to five years, and sometimes to more. Sir William Jenner's re-election for a sixth year was, therefore, although unusual, not wholly without precedent. Mr. Savory's is so, and probably indicates the firm resolve of the College to pursue the policy taken up when the two Colleges agreed to combine for examination purposes, which policy was further emphasized by their jointly undertaking the erection of a hall for examination and other purposes. This hall, of which the Queen laid the foundation-stone early in the year, is now rapidly approaching completion and is already a goodly structure looking down on the Thames.

The election now in progress is not wholly without medical interest. No less a personage than Dr. Balthazar Foster, President of the Council of the British Medical Association, has been defeated at Chester, which he represented in the late Parliament. Dr. Foster's defeat is, doubtless, due to his acceptance of Mr. Gladstone's Home Rule scheme. Dr. Alfred Carpenter has tried another constituency at this election, but is again unsuccessful. Mr. Ernest Hart apparently had enough of the fray last time, and has judged it most prudent not to make a further bid for parliamentary honors. Surgeon-Major Evatt came forward at Woolwich as a Gladstonite, but was rejected. On the other hand, Dr. Farquharson has been successful in retaining his seat in Aberdeenshire in spite of his conversion to Home Rule.

In January next another election will take place—one of much less importance, but still not without interest to our own profession—I mean the election, by the medical practitioners of the three kingdoms, of five gentlemen to represent them in the General Medical Council. Of these direct representatives three are to be elected by the practioners of England and Wales. Conjecture is already busy as to who these are to be.

I find I was a little too liberal in attributing charitable feelings to theatre-goers. The sum raised for the Hospital Sunday Fund by the collecting boxes placed in theatres only amounts to just over a hundred pounds—a very paltry sum, considering what Londoners spend in amusements.

THE AFTER-TREATMENT IN CATARACT AND IRIDECTOMY OPERATIONS.

To the Editor of The Medical Record.

SIR: I clip the following from your journal of July 10, 1886:

"A REVOLUTION IN THE AFTER-TREATMENT OF CATARACT AND IRIDECTOMY OPERATIONS.

"We believe that it is only ophthalmic surgeons who, after operating, submit their patients to the horrors of the dungeon, obliging them, in the language of the contemporaneous drama,

"'To lie in solemn silence in a dark, damp dock.'

But there have now arisen certain gentlemen who have the boldness to decry this practice as unnecessary, and even hurtful. At the St. Louis meeting of the American Medical Association, Dr. Michel advocated the plan of using a light bandage to the eyes after cataract operations and iridectomies, and allowing the patients to be in a lighted room, where friends can come and read to them. Dr. Michel's plan was not favorably received at St. Louis, but it has been tried by Dr. Chisolm, of Baltimore, who reports fourteen cataracts and four iridectomies treated in this way. The method in detail is simply this: After the removal of a cataract or the performance of an iridectomy, the eyes if a cataract, the eye if an iridectomy, is closed in its normal position and a bit of isinglass plaster, about two and a half inches long by one inch wide, is then rendered flaccid by immersion in some germicide fluid and is neatly applied to the surface of the closed lids. When dried this forms a close, firm band. The patient is then allowed the full liberty of his room. In every case thus far operated upon by Dr. Chisolm the results have been uniformly good, and he has consequently abandoned the old method."

In 1869, seventeen years ago, I read a paper before the American Ophthalmological Society, under the title of "A Method of Dressing Eyes after Cataract Extractions and other Ophthalmic Operations requiring Rest by Exclusion of Light." In that paper I argued against heavy bandages, and showed how, in my experience, it was possible to give eyes rest after capital ophthalmic operations, by closing the eyelids with strips of isinglass plaster and a partial black silk mask. In that paper the following statements, among others of like import, were made, viz.: "That it is a clinical desideratum to be able to treat a case of ophthalmic surgery in a well-lighted room without admitting light to the wounded organ." Then speaking further of the method of dressing I say: "Such a dressing makes it easy to surround old and feeble subjects with an atmosphere chemically fitted by direct light for purposes of respiration, and thus to quicken the vital forces and lessen the dangers which spring from delayed or perverted reparative processes. It (light) favors regular and easy care of the patient, and the performance of such offices as may pertain to his comfort or safety. It (light) permits, at proper times, such entertainment as may tend to give pleasant occupation to the mind and banish the apprehension and dread which always exist to a greater or less degree, in the case of those who are served in the dark by groping or stumbling attendants." "There should be fresh air, influenced by the presence of sunlight, for the patient to breathe."

In 1868 the Brooklyn Eye and Ear Hospital was opened. In its wards there was provided as much light as may be found in any general hospital. In 1869 the Manhattan Eye and Ear Hospital was opened in New York. Its wards always have been light and airy.

For more than twenty years the writer has taught in the College of Physicians and Surgeons, and elsewhere, the doctrine of the value of light in the wards of an ophthalmic hospital.

C. R. AGNEW, M.D.

ICE-CREAM POISONING—VANILLISM.

To the Editor of The Medical Record.

SIR: In your issue of this date you refer to the numerous cases of ice-cream poisoning which have been recently reported, and notably to the Michigan case, in which one hundred and forty-three persons exhibited symptoms of irritant poisoning from eating ice-cream. The *Evening Post* of the same date contains a report from Charleston, Ill., giving an account of the poisoning of fifty persons from the same cause. In addition to these veritable epidemics of ice-cream poisoning, we hear almost every day of individuals or entire families having been poisoned by eating ice-cream, pies, and other alimentary preparations.

The symptoms in all these cases are essentially the same, viz.: Burning, colicky pains, vomiting, purging, great prostration, sometimes convulsions, rarely, however, terminating fatally. The symptoms are essentially those of acute gastro-intestinal irritation, closely resembling those of cholerine, and suggesting the action of an acrid metallic poison as the exciting cause. It is a note-

worthy fact, however, that the most careful clinical analysis of the offending food has always failed to detect the presence of arsenic, copper, tin, or other metallic poisons. Professor Bartley, chemist of the Brooklyn Board of Health, has suggested that poisoning from eating ice-cream and pastry may be due to the poor grade of gelatine used, and its subsequent rapid decomposition. Professor Vaughan, who has analyzed specimens of the Michigan cream, claims to have solved the etiological mystery by the discovery of a new poison, which he terms tyrotoxicin, and which he asserts is due to the decomposition of milk kept in unclean vessels. The conditions for its generation were, however, not present in the recent New Jersey cases of poisoning, since, according to the testimony, the cans containing the milk and those used in the preparation of the cream had been carefully washed and scoured; besides, the occurrence of numerous cases of poisoning from eating pies, pastries, and simple farinaceous puddings, cooked in porcelain vessels, cannot be explained upon the theory of Professor Vaughan's somewhat hypothetical substance.

It is a matter of surprise to me that in the explanation of these toxic phenomena, a possible, and in my opinion, an exceedingly probable cause, has been entirely overlooked by these observers. I refer to the poisonous properties of the flavoring extract. It is, to say the least, a pertinent and suggestive fact that in all the cases of poisoning above mentioned vanilla has been the flavoring extract employed.

Some time ago, while investigating the incidental effects of drugs upon the skin, I came across a number of references, in French and German literature, to the local irritant action of the vanilla bean upon the skin. Precisely analogous effects are produced upon the mucous membranes, besides a train of neurotic symptoms. These toxic phenomena have been grouped by French authorities under the general term "Vanillism."

In preparing vanilla for market, the vanilla-pods are classified according to their size and quality, the quality depending upon the greater or less abundance of a substance which exudes from the pod and crystallizes upon the surface in the shape of white, frost-like needles. In order to prevent the dissemination of these crystals, the pods are frequently covered with a protective coating of the oil of the cashew nut. Cardol, or the oil of the cashew, is a most powerful irritant, simple contact with the skin causing vesicular, erysipelatous, and other cutaneous eruptions.

The workmen employed in cleaning, picking over, and assorting the vanilla-pods according to their quality, are liable to various toxic accidents, and are often compelled to change their vocation on this account. The irritant effects upon the skin are first manifest in an itching of the hands, face, and other exposed parts. The skin becomes swollen and the seat of an exceedingly pruriginous papular erruption, more or less extended, and which is followed by desquamation. It is often accompanied by blepharitis, coryza, and other signs of irritation of the mucous membranes.

The nervous symptoms are headache, vertigo, lassitude, muscular pains, great prostration, vesical irritation, and sometimes genesic excitement.

Various theories have been suggested as to the nature of the irritant principle: Schroff attributed the toxic accidents to the cardol with which the pods are coated. Rosenthal thought it was because the pods were gathered when green, as it is well known that the juice of the unripe fruit is an active irritant. According to Paget, a certain class of vanilla-pods, called *Vanilons*, which are of poor quality and entirely unfit for alimentary use, are responsible for these accidents. By others it is claimed that the irritating effects are due to the presence of a particular parasite, an acarus, which infests the pods.

In Europe the vanilla used in flavoring ices, pastries, etc., has been long recognized as a prolific source of poisoning. Over thirty years ago Orfila reported cases of poisoning from eating vanilla ices. Since then numerous cases of similar nature have been reported in Berlin, Vienna, and various cities of Europe. In the endeavor to trace the cause of these toxic accidents, the most elaborate chemical investigation proved the absence of any metallic irritant, and identified the vanilla, used in the flavoring, as the vehicle of the poison.

To this it may be objected that a substitute for the vanilla bean is often used in the manufacture of cheap ice-cream. Artificial "vanillin," as it is termed, is made from coniferin, found in the sap of the pine. In the manufacture of this extract, bichromate of potassium, an extremely irritating substance, is largely employed. It is hardly probable that the process of purification is so perfect as to remove all traces of this agent.

The object of this communication is not to cast discredit upon Professor Vaughan's alleged discovery, but rather to direct the attention of your readers to what I conceive to be the most plausible explanation of the causation of ice-cream poisoning.

PRINCE A. MORROW, M.D.

[illegible]

LAPAROTOMY IN GUNSHOT WOUNDS.

[illegible]

SIR: In your issue of July 10th appears a letter from Dr. Robert Tilley, claiming for Professor C. T. Parkes, of Chicago, priority in showing that laparotomy should be performed in penetrating abdominal wounds.

The experiments of Professor Parkes' work were upon dogs, and under conditions widely differing from those with which the surgeon has to contend in the human: these experiments were referred to by Dr. W. T. Bull, when reporting his first successful case. In the *New York Medical Journal* of February 14, 1885, he says: "The propriety of exploring the abdomen for gunshot wounds has been amply discussed by many surgeons, both here and abroad—Otis, Sims, Gross, Dugus, McGuire, Kinloch, and Parkes in this country; Legouest, in France, and Nussbaum in Germany, have urgently advocated operative interference."

These writers, however, were unable to adduce a single successful case, and it remained for Dr. Bull to clearly demonstrate the now generally acknowledged fact, that with perfect antiseptic precautions and the most thorough attention to detail, laparotomy may be successfully employed in penetrating wounds of the abdomen, and should be so employed in all suitable cases.

That the "chaotic" ideas of *The Lancet* are not altogether entertained abroad is shown by the fact that in "A Manual of Surgery," edited by Mr. Frederick Treves, of London, and published during the present year, full credit in this respect is accorded to Dr. Bull.

During the winter of 1883–84, Dr. Bull advised the house staff of the Chambers Street Hospital, on which I was at that time serving, to watch for a case of penetrating gunshot wound, stating his conviction that laparotomy was indicated in such cases. This was prior to the publication of Professor Parkes' experiments.

CHARLES A. POWERS, M.D.

IS THERE AIR WITHOUT MICROBES?

[illegible]

SIR: In an editorial entitled "Opposition to Theories of Microbial Infections," in your issue of June 12, 1886, you quote, with comments that amount almost to a declaration of neutrality, the following among other sentences from a paper on cataract operations by Dr. B. I. Baldwin, of Alabama: "There is bread that hath no leaven, and air as well without germs." If this statement means anything, it must mean that there is air with which we ordinarily come in contact that is free from germs. It would be totally irrelevant to the subject if it

referred to the air above the clouds, of which it is probably true.

What are the facts regarding the existence of germs in the air?

Tyndall's experiments in the Royal Institution are too well known to require detailed description. Infusions of nutrient substances were exposed in open test-tubes in the air of a room, with the uniform result that germs were deposited from the air, and the fluids rendered rapidly opaque by their proliferation. By a calculation based upon the space occupied by each tube and the time required for infection, Tyndall estimates about seven thousand germs in each cubic foot of space in the room; but he adds: "This, moreover, would only be a fraction—probably a small fraction—of the germs really present in the air. In his presidential address to the British Association at Liverpool, Professor Huxley ventured the statement that myriads of germs are floating in our atmosphere. Certain experimenters have rashly ridiculed this statement. In view of the foregoing calculations it, however, expresses the soberest fact."

Everyone who has practised culture experiments knows how difficult it is to avoid the introduction of germs into test-tubes, flasks, etc., if they are exposed but for a moment to superimposed strata of air, thus allowing the particulate matter, which is composed largely of germs, to gravitate into it.

It may be objected that these experiments were made in the laboratory of the Royal Institution, where repeated experimentation had polluted the air. This objection, fully anticipated by Tyndall, is fairly answered by the repetition of these experiments with precisely similar results by Mr. Darwin in his study at Down, in Sir John Lubbock's study, and at the Kew Gardens.

But if "there is air without germs," where must we go to find it? Certainly not in any atmosphere where surgical procedures are likely to transpire. The ordinary conditions of social life and relations are such that *their atmosphere is never free from germs.* Professor Miguel, in his investigations at the Observatoire de Montsouris, near Paris, has, indeed, failed to find germs at a height of six to twelve thousand feet. But, descending to lower levels, he finds them gradually increasing until, in the atmosphere of Paris, he estimates about two thousand germs to the cubic foot. There is no reason to believe that the atmosphere of populous districts has a cubic foot of air free from germs; while there is evidence, abundant and irrefutable, proving their uniform presence in immense numbers wherever sickness and accidents and surgical operations are likely to occur. Perhaps there is air without germs, but Dr. Baldwin's cases will have to move out of Alabama or go up in a balloon to find it. Alabama may have bread without leaven, but it can be safely assumed that it has no air within one hundred feet of *terra firma* without germs.

The pernicious effects of air upon accident and operation wounds has been fully recognized for three centuries. During the sixteenth century it was recognized by Ambrose Paré, Jean Andre Delacroix, Wurtz, Fallopius, and others; in the seventeenth century by Wiseman, and others; in the eighteenth century by Belloste, Parmanus, Anel, Boerhaave, Bell, Hugh Munro, James Latta, and most completely of all by Abernethy (1793). It is proper to state that these views were opposed by John Hunter and John Bell. It would be impossible within proper space to refer to the works of those who, in the present century, have aided in establishing the fact that the ingress of ordinary air to wounds is always fraught with a danger which varies in degree and kind with the conditions of the atmosphere. Our knowledge of atmospheric conditions and of wound processes now enables us to positively affirm that these dangers are exclusively dependent upon the kind of germinal matter which the air contains. It is certain that if it contains none, its access to a wound, at proper temperature, can do no possible harm. It is also equally certain that if there is any germinal matter in the air, its introduction into wounds may vary from the slightest disturbance to the death of the patient.

Were it not for the introduction of these germs all wounds would heal without suppuration; for we must now accept the dictions that *without microbes there can be no pus.* Whatever doubt there may have been about this question seems to have been removed by the recent prize essay of George Klemperer, an undergraduate of Berlin University. He has shown with apparent conclusiveness that chemical irritants may produce "coagulation necrosis," but cannot cause suppuration. As editorially remarked in the "Annals of Surgery," "it is not likely that the maxim that micro-organisms are the cause of all suppuration will be again called in question in future."

No amount of witticism or ridicule will explain away or alter the rôle of these organisms. An appeal to the "all-wise and ever-merciful Maker" in such a relation, is the merest bathos, and unworthy a scientific discussion. It would be just as rational to argue the non-existence of cataract, glaucoma, or yellow fever, because they are not consonant with somebody's conception of the "all-wise and ever-merciful Maker."

Of course, it is not claimed that all germs are pathogenic. But it is claimed that whether the germs in a particular stratum of air which comes in contact with a wound are pathogenic or not can only be answered with a certain degree of probability, unless culture experiments have given to the question a definite solution. The morbid processes which they excite in wounds are very decisive "culture experiments," which ought, hereafter, to be called *culture crimes.* The only safety is in protecting wounds from contact with the air, unless strained of floating matter, or purified by chemicals. Cleanliness *is* the great desideratum. Asepsis is the object of anti-sepsis; and if it can be obtained without the use of chemical irritants, so much the better. But to deny the existence of germs in the floating matter of the air—germs which it is possible may have been wafted from pyæmic abscesses, or scarlatinal desquamations—is to deny facts which are as definitely established as the composition of water, and are much easier of demonstration.

The brilliant results obtained by Mr. Lawson Tait and others show what is possible by a strict and scientific regard for cleanliness. The comparative rarity of wound infection, and the invariable infection of dead nutrient matter, proves that there is something in living structures which resists germ development. But this resistance is not by any means universal. Mr. Tait himself says: "What condition of the system it is which is favorable to operations is almost unknown. . . . I am perfectly certain that apparent perfect health is by no means a certain indication of a power of resistance to those conditions, whatever they be, which result in so-called septic poisoning."

In view of this uncertainty, and the further uncertainty regarding the specific nature of the germs in any given stratum of air, and in view of the clinical fact, established by almost universal experience, that access to a wound is injurious, is it not safer, nay more, is not our imperative duty to prevent, so far as possible, the introduction of germinal matter from the air into wounds?

Respectfully, G. W. McCaskey.

Fort Wayne, Ind., June 28, 1886.

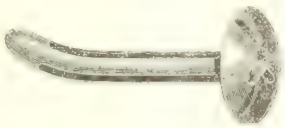
Dr. Cutter's Dictionary.—A German-Japanese medical dictionary has just been published in Tokio. It was compiled by Dr. Shigu, a government examiner in medicine, and Messrs. Take and Shibata, officers of the Sanitary Bureau. The work contains 1,400 German terms, with definitions in Japanese, and it is stated in the preface that it is based upon the "Dictionary of German Terms used in Medicine" compiled by Dr. George R. Cutter of this city.

New Instruments.

A MODIFIED INTRA-UTERINE PESSARY.

BY H. L. BOLDT, M.D.,

THE accompanying cut represents a pessary made for me by Messrs. J. Reynders & Co. It will be seen that it has three deep grooves, which connect with sufficiently large openings in the cup at the base, thereby allowing



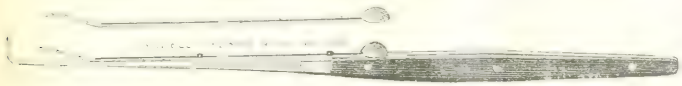
for free drainage from the entire body of the uterus, the stems heretofore in use permitting drainage only from a circumscribed portion, either at the fundus or on one side, if precaution was taken at all to secure it. The upper third of the stem is slightly curved, to facilitate its introduction, but there is also a set of straight pessaries made, or the curved one can be straightened in the usual way, if it is preferable to use a straight instrument in the case. The sizes are different. I have had the set made in four, thickness and length of stem variable. A small tampon of carbolated absorbent cotton placed against the cup, which has its concavity directed toward the uterus, is sufficient to keep the instrument *in situ*. The stem can be removed at intervals to suit the operator. The slight amount of extra trouble which the cleaning of the grooves gives, is, I think, amply repaid by the thorough drainage.

A MODIFED SIMS TENACULUM.

BY R. C. M. PAGE, M.D.,

NEW YORK.

FROM the fact that Sims' uterine tenaculum in the hands of most surgeons easily slips out of tissue, thus prolonging an operation unnecessarily in many instances, various tissue-forceps, double tenacula, and the like have been devised. But they are all more or less clumsy or difficult to manipulate. Perry's barbed tenaculum is rendered almost useless owing to the difficulty and inconvenience of withdrawing it. The instrument I now de-



sire to place before the profession is Sims' tenaculum, with a slide on it which prevents it from slipping, and is especially useful in operations on vaginal tissue. It possesses the advantages of simplicity and convenience.

1 West Thirty-third Street, March 1, 1886.

MEDICAL PRACTICE IN NEW ZEALAND.—Dr. Withers, of the *Weekly Medical Review*, of Laurence, New Zealand, writes that in New Zealand, with a population of 600,000, there are about three hundred duly qualified medical practitioners, being at the rate of one to every 2,000 of the population. Up to the present time there have been several local medical societies, but a strong movement is now on foot for the union of all these into one great medical association. By doing this, considerable influence can be brought to bear on the House of Representatives to promote legislation on matters affecting the profession; and other matters, such as the repression of quackery, will be in responsible hands.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 10 to July 17, 1886.

GIBSON, JOHN B., Major and Surgeon. Granted leave of absence for three months, to take effect about August 1st. S. O. 158, A. G. O., July 10, 1886.

BARNETT, RICHARDS, Captain and Assistant Surgeon. Leave of absence extended six months on surgeon's certificate of disability. S. O. 162, A. G. O., July 15, 1886.

GARDNER, EDWIN F., Captain and Assistant Surgeon. Granted leave of absence for two months. S. O. 158, A. G. O., July 10, 1886.

OWEN, WILLIAM O., JR., First Lieutenant and Assistant Surgeon. Ordered for duty at Fort Schuyler, New York Harbor. S. O. 84, Division of the Atlantic, July 15, 1886.

Official List of Changes in the Medical Corps of the United States Navy, for the week ending July 17, 1886.

WENTWORTH, A. R., Assistant Surgeon. Detached from the U. S. S. Brooklyn, and wait orders.

NORT, OLIVER D., Assistant Surgeon. Detached from the U. S. S. Minnesota, and to the U. S. S. Brooklyn.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 17, 1886:

Typhoid fever		
Scarlet fever		
Cerebro-spinal meningitis		

THE RESUSCITATION OF INFANTS BORN ASPHYXIATED.—Dr. E. T. Blackwell, of Cedarville, N. J., referring to the Schultz method of resuscitating the new-born child, writes that he has practised for many years a somewhat similar plan, the following description of which was published in the *Medical and Surgical Reporter*. The method consisted in tossing the child, with a quick motion, the placenta being still attached. The rapid movement causes the arms to fly up, lifting the chest-walls, and causing the infant to take in air by a sudden sob. The method may appear rude, but it has succeeded in many apparently desperate cases. It has the merit of instant applicability with very quick results, and experience with it has led the author to regard it as an unfailing means of insuring the recovery of newly born infants, apparently dying from asphyxia. In the procedure the head, neck, and shoulders are supported in the palm of one hand, while the buttocks rest in the other. The tossing may be repeated at suitable intervals as long as seems necessary.

THE DANGERS OF PROGNOSIS.—A tailor in Vienna having been told by his physician that he was suffering from an incurable disease, drew a pistol and fired two shots at his medical adviser, and then killed himself. The physician was not severely wounded, and has now recovered.

THE INJURIOUS EFFECT OF THE BANDAGE AFTER LABOR.—Dr. Wm. B. Lyman, of Wilson, Wis., regards the bandage applied after labor as a fruitful cause of subinvolution of the uterus. The weight of the organ, after delivery, is two pounds or more, and this should normally be reduced to a few ounces within a few weeks, the greater part of the change taking place during the second week. In order, he says, that this change may progress perfectly the organ should have the freest possible circulation, and this is only obtained by the perfect rest of the patient in the recumbent position, all abnormal pressure over the organ being avoided. Nature does what she can by relaxing the abdominal parietes, and distending the intestines with gas, so as to cover the uterus with an air-cushion, and thus relieve the organ from undue pressure during contraction of the abdominal muscles. Under these conditions there is free and uninterrupted circulation through the blood-vessels and lymphatics of the uterus and its appendages. But the bandage, Dr. Lyman maintains, exerts constant pressure on the organ, confining it rigidly against the walls of the false pelvis, and when a pad is also applied, the uterus is more or less impacted in the brim of the pelvis, the ligaments are stretched, and malpositions and passive congestion result. Experience has taught him, he says, that a bandage does not add to the comfort of the patient, and he believes that it should be discarded, except in certain cases where its application is clearly indicated.

OVARIOTOMY IN RUSSIA.—Dr. V. Matveyeff has collected the statistics of all the reported cases of ovariotomy performed in Russia up to the present time (*Russkaya Medetsina*, June 1, 1886). The first laparotomy was performed by Vanzetti, in Kharkoff, in 1848, but the patient died. The first successful ovariotomy was reported by Professor Krassovski, in 1862. The total number of cases was 696, of which 213, or 30.4 per cent. died. It is to be regretted that the author does not give the proportion of successful cases year by year, as in this way only is it possible to judge of the progress made.

MULTIPLE TÆNIA.—Dr. Gurfinkel writes, in the *Vratch*, that he had a patient to whom he gave extract of male fern with the result of causing the expulsion of one hundred and two tape-worms. The pieces, placed end to end, measured two hundred and thirty-eight feet. Twelve distinct heads were found.

PRIORITY IN INVENTION OF THE PNEUMATIC CABINET.—Dr. Henry B. Lathrop, of Los Angeles, Cal., writes: "The papers read by various gentlemen before the Climatological Association induce me to say from the shores of the Pacific that some, at least, of our thunder is being stolen. Early in the fall of 1884 Dr. Edward C. Folsom, of Santa Monica, made, or rather had made, at great expense, a pneumatic cabinet. The coldness of the profession and the ridicule heaped upon the theories advanced caused Dr. Folsom to abandon the investigations he had begun. From him, in January, 1885, I purchased the cabinet, and have been experimenting with it ever since. For my pains I was sent to a sort of professional Coventry, and mildly held up before the community as violating the unwritten laws of ethics. So far had this thing gone that I myself felt quite 'quacky,' when, taking up a recent copy of THE RECORD, I find myself no quack, but a pioneer in the pneumatic treatment of disease. While Dr. Folsom and myself deserve probably the priority of invention and use in this country of the cabinet for treating disease, the wider range of observation enjoyed by the gentlemen who have already written on the subject make their conclusions more valuable than any we could advance. Still, if we deserve it, we would like to claim for ourselves priority of observation. I am sorry that a close corporation has been formed for the manufacture and rental of the cabinets. Mine having been an accomplished fact before the company was started, I shall continue to use it whenever and however I please for the benefit of science and of my fellow-creatures." [We fear our correspondent's claim to priority is not well founded. By referring to THE RECORD of January 17, 1885, he will find cases there reported of patients treated in the cabinet as early as in September, 1883.—ED.]

GLEET AND STRICTURE.—In a paper on the treatment of gleet, in the *Albany Medical Annals*, Dr. O. D. Ball says that the more cases of this nature that he sees the more is he convinced that the statement of Otis that "all cases of gleet are dependent upon strictures, either of large or small calibre," is wrong. A fair proportion of these cases, he says, have no stricture, and he mentions the case of a man with an old chronic specific urethritis whose urethra admitted a No. 36 French sound with as much ease as the ordinary canal will a No. 15.

A LOW TEMPERATURE.—Dr. C. W. Suckling reports in *The Lancet* the case of a woman with myxœdema who was comatose some time before death. The pulse was 36; the respirations 12 per minute. The temperature could not be taken with the ordinary clinical thermometers, which were not graduated below 95°, the mercury not rising to within an inch of the first mark on the glass. A thermometer used for taking the temperature of baths was separated from its iron frame, on which was the graduation, and the bulb, was placed under the tongue for half an hour, the level of the mercury being marked on the stem with ink. The thermometer was again placed in its frame, and the registration was 76.5°. The next day the pulse was imperceptible at the wrist, the heart-beats being 20 per minute. The temperature, taken the same way as the day before, was 70°. During the day it was taken several times, and varied from 66° to 70°. The patient died the same night. The bath thermometer, immersed in warm water, at the end of three minutes registered 90°, a clinical thermometer 98.5°, so that the figures given represented, with perhaps the difference of a degree or two, the actual temperature in the mouth, which is one of the lowest ever recorded during life.

A CLINICAL PICTURE OF A BAD DISEASE.—A writer in one of our esteemed contemporaries in the Southwest breaks loose, and gives expression to his views rather unconventionally as follows: "Dengue is a viviparous, homogeneous, amphibious hermaphrodite from the head of 'Bitter Creek,' close to 'Wild-cat Run.' It is indigenous in Austin and spontaneous in Dallas—among hogs, dogs, cats, and other non-office seekers. It is contra-indicated in all cases where a fellow expects to engage in a prize-fight or make a 'crap.' It is bilateral, having an inside and an outside. It has no symptoms—it strikes a fellow on his way from church or in a saloon, and paralyzes him to the end of his hair, and then feels out for 'other worlds to conquer.' Its pathology is confined mostly to the whole body, skin, and mouth. It destroys a man's pugnacity and plants instead thereof humility, and a third-class case of rheumatic-gout-small-pox-fits-inflew-endways and chloroformmorbus. Those who have not had their pegs knocked from under them by this fiendish short-rib searcher, say they think they have 'had a touch of it.' To all such we wish to say: Wait till it 'touches' you up in earnest, and then you will say in the words of Horace Greeley, 'I have *wilted*.'"

EXTRA-UTERINE PREGNANCY OF SEVEN YEARS' DURATION.—Dr. John Homans reports, in the *Boston Medical and Surgical Journal* of May 20, 1886, a case of extra-uterine pregnancy, dating back seven years. Laparotomy was performed, and a tumor was discovered which contained four or five pints of a fluid resembling pus, but which was composed of a fatty granular detritus, but no pus-cells. At the bottom of this sac were found all the bones of a full-term fœtus, completely macerated and separated. The patient died about four hours after the operation.

Original Articles.

EXCISION OF THE KNEE-JOINT.

TOGETHER WITH A REPORT OF FIFTY HUNDRED AND TWENTY-NINE CASES TREATED ACCORDING TO MODERN ANTISEPTIC METHODS, AND OF A CASE OF RESECTION OF THE HAMSTRING TENDONS, TO PREVENT RELAPSE IN CHILDREN.

BY A. M. PHELPS, M.D.,

[illegible]

IN 1879 I performed a complete excision, in a case nine years of age, for destructive caries-disease of the knee-joint. The case came into my hands after the limb had become somewhat flexed, and sinuses had formed upon the outer and inner sides of the knee. I proceeded to open the joint for the purpose of exploration and establishing drainage, but found extensive disease. The entire articular surfaces of the bones were in a necrotic condition. I at once extended my incision from the inner condyle to the outer, and below the patella, describing a curve, and freely opened the joint. After sawing away the articular surface of each bone in such a manner as to allow them to come together in a slightly flexed position, and removing the patella, together with all diseased tissue in and about the joint, and excising the old sinuses, I wired the bones together and dressed the leg with plaster-of-Paris applied over the dressing, and slung it up in order to keep the part at perfect rest. Before the plaster-of-Paris became hard a large opening was cut, through which the subsequent dressings were made. The case progressed favorably and recovered, being discharged at the end of four months. Eight months subsequently the patient returned, and I found that the leg was flexed at an angle of forty-five degrees. The patient suffered some pain at the point of excision during locomotion. Upon an attempt to straighten the leg pain was produced, and also severe reflex spasm of the hamstring tendons. I at once etherized the patient, *resected the hamstring tendons* through small open wounds, and attempted to straighten the limb, but failed. I then made an incision directly across the front of the joint and sawed out a wedge-shaped piece of bone, sufficiently large to admit of straightening the limb; the leg was placed in a *perfectly straight position*, the bones wired and dressed as before. There was some shock, and fever following, which subsided after a few days. From this time the case went on to recovery, and at the end of three months was discharged, well, with one inch of shortening. A posterior splint was worn for six months. I have learned by letter that the case has never relapsed. The relapse, Mr. President, occurring in this case—which to me at that time was somewhat novel—and my observations since of several cases of this kind in the hospitals of Europe—and which, I learned from European surgeons, is by no means uncommon—induced me to accept your kind invitation to present here, at this meeting, a paper on excision of the knee-joint. Why did the case relapse? A glance at the drawing (Fig 1) will, I think, furnish a solution of the question.

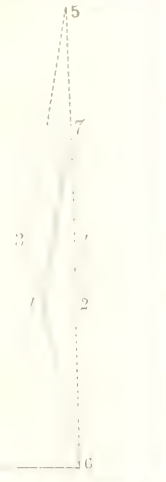

FIG. 1. [illegible] slightly [illegible] angle at 1. [illegible] acting upon this point when the limb is flexed, may produce flexion by gradual [illegible] tion causes reflex contraction of the ham[illegible] the tendons [illegible] the body and the reflex contraction of the hamstrings causes the relapse. The re[illegible] at 3.

The second case, in a boy aged ten years, was one of chronic suppurative inflammation of the knee-joint. One year before he received a blow upon the knee which produced a subacute inflammation, which gradually destroyed the joint. The leg was flexed at an angle of forty-five degrees, and the capsule was distended with fluid. An exploratory incision was made just above the inner condyle. Upon introducing the finger the ends of the bones were found denuded of cartilage and the joint filled with a gelatinous material. After a thorough washing, so as to expose the parts, I found the bone so extensively diseased that an excision of the entire joint seemed to promise the best result. The incision, as already described, was made. With a saw the articular surfaces were removed in such a manner as to allow the bones to be approximated in a straight line. After the removal of all diseased tissue the hamstring tendons to the extent of an inch and a half were resected through small open wounds. The bones were wired and the limb dressed the same way as in the previous case. A small amount of suppuration occurred in the soft parts. The recovery was perfect, and after three months the patient was discharged with bony union. The limb has never relapsed, and is as useful as a stiff limb can be with three-fourths of an inch shortening.

CASE III.—Aged sixteen years, chronic disease, subluxation, and necrosis of the head of the femur; possesses no special point of interest. The steps, as already given, with the exception of dressing, were taken; the case recovered and was discharged at the end of three months with a good limb; no pus or fever occurring after the operation.

CASE IV.—Aged twenty years, chronic inflammation from injury ten years previous. The leg was flexed and the joint filled with a cheesy substance. Crepitation could be distinctly felt and heard. An exploratory examination by incision revealed the fact that extensive disease of the bones was present. Amputation or excision was to be decided upon. An incision beginning at the inner condyle, and carried directly over the centre of the patella, which was sawn through, after Volkmann, to the external condyle, exposed the joint most perfectly. Not only was there extensive bone disease, as seen in those specimens which were removed, but the entire capsule was thickened and infiltrated. With curved scissors and forceps all diseased tissues, including the capsule of the joint, were removed. The joint-surface of the patella was also scraped off. The bones and the patella were now

[1] Read before the New York State Medical Society, [illegible]

wired, which nicely coaptated them, and the wound closed. Large drainage-tubes were inserted. Permanent dressings were applied, consisting of sublimated gauze and wood-wool bags, extending from the foot to the body, and over all the plaster-of-Paris bandage. The leg was slung up. At the first dressing, seven days later, the wound had entirely healed, except at the point of drainage. The drainage-tubes were removed and the leg again dressed as before. Three weeks later, at the second dressing, the wound was found perfectly healed. At the end of two months the patient was out on crutches. Four months from the time of the operation he walked on the leg. In this case there was no rise of temperature above 100° F.; pulse never above 90; no pus or pain, and the wound united by primary union as in the preceding case.

Case V.—Aged thirteen years; male; suffering from chronic inflammation of the knee-joint for six years. Leg flexed at an angle of forty-five degrees. The joint was found filled with fungus and there was extensive disease of the bones. I proceeded to perform an operation according to Neuber, of Kiel, Germany, and which, I believe, has not heretofore been resorted to in this country (see Figs. 2 and 3). An incision, extending from the outer con-

Fig. 2.

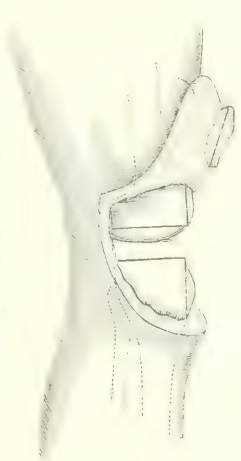

Fig. 3.

dyle, underneath the patella to the inner condyle, brought the joint into view. The heads of the femur and tibia were sawed square, parallel with the joint surfaces. The posterior projecting portions of the condyles were also removed. The patella was now joined at its under surfaces and securely nailed to the front of the tibia and femur with strong steel nails. A wire was also inserted on each side, from tibia to femur, to more securely hold the bones. The case was dressed the same as the preceding. I neglected to say that the hamstrings were resected, and all disease removed from in and about the joint. The case developed no fever or pus, and but little pain, and healed perfectly under the dressings in three weeks. Patient walks well with a perfectly straight leg.

Cases VI. and VII.—Male, twenty-one years of age; female, twenty years of age; both chronic inflammation of the knee-joint, of several years' standing, with extensive bone disease, were resected before the class in Mary Fletcher Hospital, University of Vermont. Fenwick operation was performed. The cutting of the bones constitutes the distinguishing feature (see Fig. 3). The cases were dressed similarly to the preceding case, and healed perfectly under two dressings, in three weeks, without pus or fever above 101°, and with no considerable degree of pain. Discharged from the hospital in seven weeks, cured.

Case VIII.—Female, aged nineteen, extensive fungous disease of joint, with osteitis of the head of femur. The joint was opened for exploration and washing out, but the disease was found to be so extensive that immediate excision or amputation was decided upon. Excision was performed before the class in the amphitheatre of the above-named hospital. The excessive administration of ether caused death, which took place soon after the completion of the operation. The operation of Dr. Fenwick was performed. The microscope revealed the presence of pus in the cancellated structure of the bone.

The favorable course in Cases III., IV., V., VI., and VII., was due to the perfect coaptation of the bony and soft parts, good drainage, and antiseptic dressings which did not require constant change; thus allowing the parts to remain at perfect rest, and at the same time, by the method of their application, exercising equal pressure, which regulated the circulation, preventing swelling, and obliterated cavities or pockets which might have existed when the soft parts were brought together. In addition to all this the carrying out from the beginning to the completion of the operation, and at the subsequent dressings, the most scrupulous details of modern antiseptic methods.

Want of time compels me to thus briefly report these eight cases, with nine operations.

The end sought in all operations of excision of the knee-joint should be:

1st. To remove all diseased tissue, including the capsule of the joint.

2d. To make the incisions in such a manner as to furnish easy access to every part of the joint and furnish perfect drainage.

3d. To restore all tissues to their normal position without leaving cavities.

4th. To get perfect drainage.

5th. To insure absolute immobility of parts after the operation.

6th. In children, after *resection of the flexor tendons, placing the limb straight and utilizing the patella when practicable, to prevent relapse.*

The operations which are preferable and meet these indications best are Volkmann's, Fenwick's, and Neuber's.

If these requirements are carefully followed out, and if all diseased tissue is removed, including the capsule of the joint, the surgeon will have to deal simply with compound fracture, and the mortality from the operation ought not to be greater than from accidental compound fracture of the femur which has been carefully wired and dressed according to the light which surgery of the nineteenth century sheds. The peculiar advantage of sawing the

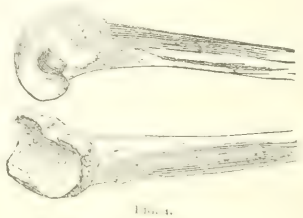

Fig. 4.

bones after Fenwick's method keeps them in position, even if a slight subsequent flexion occurs, as the head of the femur fits the socket-head of the tibia similarly to a hinged joint. Should flexions occur in cases where the bone is cut squarely across, a cavity would be left on the anterior side, making a pocket for the accumulation of secretions between the ends of the bones, which would be quite likely to prevent bony union or defeat the object of the operation by long-continued suppuration. The extreme difficulty, however, of cutting the bones to fit perfectly, without leaving cavities between their surfaces, after Fenwick's method, is quite apparent, as curves are more difficult to make than angles.

In Volkmann's and Neuber's methods the patella plays the important part of holding the bones in perfect coaptation; in Neuber's, it forms a splice of the bones; while in Volkmann's, by the action of the quadriceps muscle and its immediate union to the surface of the femur and tibia which has been prepared for it, the patella performs the same function. In children the patella, if not extensively diseased, should be thus utilized. This, in connection with placing the limb in a perfectly straight position, and the resection of the hamstring tendons, will, I believe, prevent the disastrous relapses so frequently occurring in subjects under fourteen years of age. A posterior splint should also be worn for one year or more.

Tenotomy of the hamstring tendons has been frequently performed to allow the straightening of the limb before the operation, otherwise a greater amount of bone would be sacrificed. But as to resection of all the flexor tendons to prevent their subsequent action in producing relapse in children, I am not aware of its ever having been done prior to the four cases which I here report. After an excision, the leg, so far as the knee-joint is concerned, becomes a crutch, and, were all muscles and tendons which act upon it removed, the power of locomotion would not be affected. Therefore a resection of one or two inches of the hamstring tendons, through two small incisions, when done antiseptically, adds nothing to the danger of the operation.

The mortality from excision of the knee-joint, as compiled by Culbertson, from all sources in private practice is: Under five years of age, 38.9 per cent.; between five and ten years, 16.2 per cent.; between ten and fifteen years, 17.2 per cent.; between fif-

teen and twenty years, 30.1 per cent.; between twenty and twenty-five years, 39.4 per cent.; between twenty-five and thirty years, 37 per cent.; between thirty and forty years, 41.5 per cent.; over forty years, 52.6 per cent.; an average in all cases of 29.8 per cent. These figures show the most favorable age to be between five and ten. But there is more danger of relapse,-non-bony union, and permanent shortening from cutting into the epiphyseal line at that age. Puberty is the most favorable age. From the same compilation the mortality from gunshot wounds is 75 per cent.; other injuries, 39 per cent.; disease, 31 per cent.; deformity, 13 per cent. The mortality from military amputations is: In the lower third of thigh, 50 per cent.; hospital amputations, 35 to 57 per cent.; amputations for disease, 22 per cent. Edwards' plates of military excisions show a mortality without excision of 80 per cent.; with excision, 80 per cent.; amputation, 73 per cent., being 7 per cent. in favor of amputation in gunshot wounds.

These statistics are made up from foreign wars and our late rebellion. If the above statistics are correct, and modern methods of operating and dressing were followed, clearly excision of the knee-joint should be abandoned in military surgery and also in gunshot wounds in which the bones of the joint are extensively comminuted. But these compilations were made in 1877, from cases many of which were operated upon prior to the advent of the more scientific antiseptic methods of to-day.

In Culbertson's tables (see "Prize Essay," 1876), 684 cases of excision of the knee-joint for disease, injury, and deformity are reported. I find 51 deaths from pyæmia, and septicæmia, 31 from exhaustion, 6 from erysipelas, 3 from hectica, 2 from phlebitis, 4 from secondary hemorrhage, and 1 from acute suppuration, a large majority of which are due to wound infections—a death-rate from all causes of 14.47 per cent.; from pyæmia and septicæmia alone of 7.45 per cent.

A glance at the tables appended, which have been carefully compiled from sources known to be rigidly antiseptic, and all since 1878, will furnish a key to the large per cent. of mortality prior to that date. In 329 operations are found 31 deaths—a mortality of 9.42 per cent. Excluding 21 cases of deaths from phthisis and other diseases not dependent upon the operation, gives a mortality of only 3.03 per cent. In 329 cases there are only 3 cases of septicæmia and 1 of pyæmia. Add to 9.42 per cent. the 14.47 per cent. death-rate from Culbertson's tables from wound-infection gives 23.89 per cent., which is nearly the exact rate furnished in his tables as the mortality following excision of the knee-joint. The reduction of mortality from 29.8 per cent. to 9.42 per cent. is sufficient evidence, I think, to convince the profession of the efficacy of modern antiseptic methods, and this has been mainly due to the prevention of wound infection, as I have already shown. Deducting the 21 cases of death not due to the operation reduces the mortality to 3.03 per cent. (see Table II.). The same 684 cases show, by Culbertson's tables, 77 amputations, or 11.25 per cent.; in the 329 cases reported in this paper 19, or 5.77 per cent.

I will state that the class of diseases, and the causes for which excision has been performed, vary but little in Culbertson's compilation and those of this paper. In his 684 cases are to be found less than a dozen cases of excision for recent injury. Another noticeable fact is, that in the table of Culbertson of "Excision for Deformities" there are 53 cases with no amputations, but 7 deaths—5 from sepsis, 1 from pleuro-pneumonia, and 1 from tetanus. The amputations are reserved for the operations performed upon already diseased or suppurating joints, but the mortality being about thirteen per cent. is still very much larger than the present mortality furnished from operations upon already diseased or suppurating joints, and, as stated by Culbertson, the per cent. is in one class of cases 29.8, the other 13. Wound-infection then was quite common, and difficult to do away with, when suppurative processes were already found in joints; now they are easily managed.

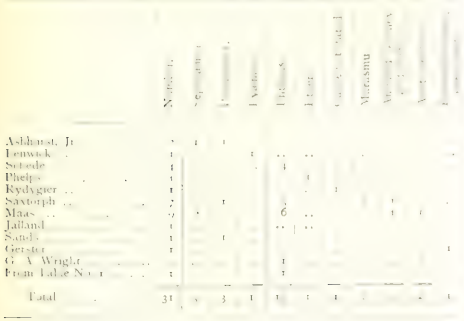
* Per cent. of amputations following excision, 5.77.

Cases for excision of the knee-joint should be carefully selected. In children under eight years of age it should never be resorted to, except in cases of destruction of the entire joint, and not until after other means have failed. It is better at this age to excise through exploratory openings such portions of bone and tissue as are found diseased, using the gouge-scoop and chisel thoroughly, establishing perfect drainage, fixation, and extension. Chronic diseases with deformity, either purulent or non-purulent, not yielding to the ordinary methods of treatment, are suitable cases at any age. Extensive suppuration, burrowing of pus, with many sinuses distributed about the joint, and extensive necrosis, making it difficult, uncertain, or impossible to remove all diseased tissue, are cases more suitable for amputation. Deformities from long-standing arthritis, with but little bone disease, limited to the articulations, are very favorable cases for excision. Anchylosis in bad position, compound luxation, and subluxations from long standing joint diseases should be excised.

Many cases of joint disease among the poor, which might by long treatment be cured, if the patients could spare time from their work, should be excised, because they are then restored soon to health; when, if the opera-

tion were not performed, amputation would quite likely be demanded in after-years, owing to frequent relapses.

TABLE III.—*Showing Cause of Death.*



I desire to acknowledge the invaluable assistance of Dr. Robert T. Morris, of New York, in furnishing to me the statistics of cases which he translated from foreign journals for publication in this paper.

A REVOLUTION COMPLETE IN THE AFTER-TREATMENT OF CATARACT OPERATIONS.

BY JULIAN J. CHISOLM, M.D.,

LATE SURGEON, U.S.A.

RECENT experiences at the Presbyterian Eye and Ear Charity Hospital of Baltimore City tend to show that needless and annoying restraint is practised upon cataract patients by surgeons who adhere to the time-honored method of bandaging, over compresses, eyes recently operated upon for the extraction of opaque lenses, or for the removal of pieces of iris, as in iridectomies. At the meeting of the National Medical Association in St. Louis, I was conversing with Dr. Charles E. Michel, of that city, on the comfort which cocaine gave to eye surgeons, when he mentioned that its introduction, and the discarding of general anæsthetics, with the accompanying vomiting, had enabled him to modify the eye-dressings even to the entire abandonment of the historic eye bandage. He had substituted for it a piece of gold-beater's skin for securing the eyelids, and found it an ample dressing. He also treated cataract patients no longer in dark rooms.

To me, accustomed to follow in the universally trodden path, and of applying over each eye a piece of soft cloth, then a mass of raw cotton as an elastic pad, then a well-secured bandage for obtaining and insuring (?) uniform and continued pressure, this was a startling innovation. It impressed me to such an extent that at the afternoon meeting of the Ophthalmological Section, a large attendance being present, I related my conversation of the morning, and asked if anyone had had any experience with adhesive straps and light rooms for the after-treatment of cataract cases. The voice of the Section was one of warning, that such an innovation would be fraught with great danger, and that we had better adhere to the course which had been shown by ophthalmic surgeons in all parts of the world to be a successful method of dressing. With compresses, bandages, and restraint in bed, in dark rooms, thousands of blind cataract patients had been made to see, and that, therefore, we had better not disturb so well-established and so successful a method. In discussing the subject I used in argument that because millions of women, in all parts of the world, after confinement, had been surrounded by an abdominal band, called a supporter, and had survived it, this had not deterred modern obstetricians from discarding what in most cases they knew to be more an abominable than an abdominal support; and that possibly modern eye surgeons would have to discard eye bandages for similar reasons.

Having a large amount of eye material at my disposal I promised the Ophthalmological Section that I would test this mode of dressing cataract cases at once, and would promptly report my experiments, if successful, so that through it eye patients might escape the annoyances to which they are now universally exposed.

My experiences by the new method of dressing have been so markedly satisfactory as to warrant me in discarding forever the stereotyped cataract compresses and bandages from the Presbyterian Eye Hospital. From this time forth a piece of white isinglass plaster will be my sole dressing for cataract and iridectomy patients, to the comfortable exclusion of all water applications.

Here is the detail of dressings and treatment which I now pursue in cataract cases. All cataract extractions are made under a four per cent. solution of cocaine. A few drops in the eye, the patient lying on the back, so as to retain the drops in contact with the cornea, will in ten minutes give all the immunity from pain desired. This solution has always served me well. Since the introduction of cocaine into surgical practice, now eighteen months, 182 operations for cataract extraction, besides a number of needle operations for soft and capsular cataract, have been performed at the Presbyterian Eye and Ear Charity Hospital under its painless influences. I perform Graefe's modified linear incision without conjunctival flap, which, with the exception of the puncture and counter-puncture, places the incision entirely in the clear cornea. The iris is seized at its pupillary border, from the centre of the corneal opening, and when well drawn out is divided, so that one clip of the scissors usually perfects the iridectomy. This course insures a small, well-shaped pupil. The capsule is opened in its upper front portion, and the lens is pushed out by stroking the cornea upward with a rubber spoon. Should I find the capsule thickened, after clearing away all lens detritus, I pass into the anterior chamber Mathieu's iris forceps and remove by traction the whole capsule. This leaves a beautifully clear pupil. The surface of the eye is then washed with an antiseptic fluid—1 part of the biniodide of mercury to 20,000 of water is what I am now using—a four-grain solution of atropia is put on the cornea, and the lids are closed, after testing vision by counting fingers. I then take a piece of isinglass plaster, about an inch and a half wide and two and a half inches long. It is dipped in the antiseptic liquid, which happens to be conveniently at hand, and when it becomes thoroughly flaccid it is evenly laid over the closed eye from brow to cheek, gently pressing it in at all points by means of a rubber spoon, so as to make it adapt itself thoroughly to the whole surface of the eyelids. Both eyes are closed in this manner if for cataract extraction, only the affected eye if the operation be an iridectomy. In a very few minutes the plaster is dry enough to insure the perfect and permanent closing of the lids.

In the Presbyterian Eye Hospital I have a number of private rooms, so that I can concentrate nearly all of my operations, both for ward patients and private patients, in this building. All operations are performed in the operating-room, on the second floor, on account of the perfect light which I can always secure in it. From the operating-table all patients walk to their rooms, often ascending two flights of stairs to reach them. When put to bed the only instruction given is not to touch the eyes. No restraint is required as to the movements of patients. They are allowed to lie on back or side, as they may find it most agreeable. Operations at the hospital are always performed between two and four o'clock in the afternoon. Patients usually restrict their supper to a cup of tea and some light bread. From the first breakfast there is no restriction put on diet. Patients are allowed to eat anything which they know will agree with them. If any restlessness or nervousness be

exhibited at bedtime, the patient is given a sleeping draught of ten grains of hydrate of chloral and twenty grains of bromide of potassium. It is not often found necessary to continue this mixture after the first night. Each patient has a bell placed on a small table near the bed and within easy reach, so that they may summon a nurse if one is needed for any purpose. Frequent visits are paid to the room by the nurse, and also by the resident physician, but the constant presence of a nurse is never required. Patients are allowed to get out of bed on calls of nature, and sit up in bed to take their meals. The private rooms and wards of the hospital are all curtained with blue shades. These are drawn down to exclude sunlight, but at no time do they make the room so dark that reading may not be indulged in by friends of the sick.

The straps are examined day by day. If they remain firmly adherent and the patient has no pain, the straps are not disturbed. If they become detached they are removed and new ones applied. On the third, fourth, and fifth day a few drops of the atropine solution are put near the edge of the plaster at the inner canthus. The solution works its way along the lashes, and some of it is felt in the eye. Not enough is put on to displace the adhesive strap.

After the second day the patients are at liberty to sit up out of bed, if they desire it. In this regard they can follow their own inclination. If the case has progressed satisfactorily the straps are removed from both eyes on the sixth day. In many cases I have done this as early as the fifth day, without any disturbance of any kind following. As the light has never been excluded from the sick-room during the strapping period, the removal of the diaphanous adhesive straps and the opening of the eyes require no change as regards light. When the eyes are now examined, and the light of the room is sufficient for this purpose without artificial means, one is at once struck with the very small degree of hyperæmia present, and the absence of photophobia and lachrymation. From the very beginning the patient stands the moderate light with no discomfort and with little weeping. When light is not excluded the eye rapidly gains strength, and in a very few days the patient can enjoy the freedom of the house without restraint. In two weeks from the day of operation, as a rule, and in some cases as early as the tenth day, patients are ready to return to their homes, using smoked glasses as a precaution against the sunlight of the street only, but not in the house.

From my recent experiences in treating eyes by this new method, and looking back from this standpoint upon my thirty years' of experience in eye surgery, I am forced to the conclusion that much of the discomfort which patients experience after cataract operations can be truly charged to the surgical dressings and restraining treatment.

In the first place, can any kind of compress and retaining bandage be applied to a recently opened cornea which will at all times, and under the varying positions of the patient's head, while lying in bed, keep up an equable pressure on the eyeball? Grant that the pressure of the ball of elastic raw cotton, which is the most easily adapted of all compresses, when gently secured by the retaining band, is uniform over the entire surface of the lids as the patient leaves the operating-table, the moment the head presses upon the pillow, and especially when the head is moved from one side to the other by the restlessness of patients, a drawing of the bandage is a necessary consequence, making the lid-pressure irregular and disturbing the corneal wound. This has ever been so, regardless of the great variety of head-bands used, and must ever continue under the commonly used methods of dressing. If we recognize the tonicity of the orbicular palpebral muscle, acting upon the thoroughly moulded tarsal cartilage, as the proper eye-splint, and the natural means of securing uniform pressure, then why should we not use it? Retain the eyelids closed by means of a light adhesive strap, an appliance which will not under any condition or at any time change the direction or degree of this tonic support, and we have truly found the means of sustaining the proper adaptation of the edges of the corneal wound for promoting speedy and perfect union. The theory of this is perfectly rational, and experience with this method of dressing eyes after cataract extractions will substantiate its efficacy.

The next point of great and grave importance is the supposed need of darkness for the successful treatment of cataract operations. This has been so earnestly pressed upon us by all authorities and by our own confirmed habits that we are all wedded to the practice. It is a revolution, indeed, to break out of this deeply worn rut in which ophthalmic surgeons in every part of the world are working.

The golden rule for successful surgery is to disturb the natural processes as little as possible, and not excite an irritable condition of the system which might be the starting-point for other and more serious disturbances.

We must all acknowledge that the every-day and all-day exposure of the eyes to light prior to cataract operations, and then the sudden transition to utter darkness of closed eyes, with pads and bandages, in dark rooms, is very positive. Treat healthy eyes in a similar manner, and keep it up for a week, as we do our cataract patients after operation, and what would be the result? When in summer we go from our moderately shaded offices into the noonday sun our healthy, strong eyes feel very unpleasantly the transition, and, as we have all personally experienced, we know it takes some minutes before the discomfort passes off. When we go from a dark room into strong light the effect on the eyes is very disagreeable. If, after one week's incarceration in a dark cell, one is suddenly turned out into the street at midday, the acquired photophobia and hyperæmia would cause pain and weeping, and possibly bring on more serious congestion with destructive inflammation. Yet in a measure this is what we are all doing for our cataract patients. We incarcerate them in utter darkness, and after keeping them there for a given number of days expect good to come from this very unphysiological and unreasonable proceeding. When the bandages are removed, even in a very dark room, the eyes feel sensitive and weep. We expect this, and are never disappointed in finding it, but we have failed to appreciate why it is always so.

When we remove the opaque lens from a patient's eye, with the strong light needful for operation shining directly on his face, he does not complain of the extraordinary brilliancy, because the transition is not excessive. The eye, still smarting under the surgical manipulation, and made irritable by the wounds necessarily inflicted, is not annoyed by the strong light to which it is accustomed. When the patient's eyes are now closed the lids will shut out quite as much light as did the opaque lens, and therefore it replaces the condition which had existed without annoyance for several months prior to the operation, and during which the clouded eye was not inconvenienced by light.

I can readily look back to my early experiences in surgical work when the professional world deemed it necessary in cataract cases, as well as in every other surgery, to prepare the patient weeks in advance by diet, purgatives, and annoying restraints of all kinds, thereby establishing an irritability which led to the very troubles we were so anxious to avoid. These accidents were induced by the professional and well-meaning interferences with a natural and wholesome state. At the present time none of us will hesitate to operate upon a matured cataract a few minutes after the patient enters for the first time the hospital dispensary, with his stomach full of the very recently enjoyed dinner. He feels well generally, and we leave him so, and this for his future good and our credit as modern surgeons. This is a very positive advance from a former surgery. Now let us take another very great jump for our patients' good, and our credit as

modern eye surgeon. I leave out cataract patients in a condition as little disturbed as possible from the state just prior to the operation for extraction. Close the eyelids, when closed, a sufficient protection to the cornea, a substitute for the lens removed, and retain the eyelids closed by as light an adhesive covering as you can find. Any light-colored isinglass admits light freely, and when thoroughly wetted will adjust itself snugly to every part of the lid surface, and when dry will hold on firmly. As patients up to this time have not excluded daylight from their places of abode, let us be careful to surround them with the same degree of light as that in which they have been living. Let the chamber, therefore, be pleasantly lighted and not heavily curtained. The luxury of this treatment to a patient, who, in a former experience, has had his head enveloped by bandages is truly enjoyable, and the friends in attendance about him will certainly appreciate the comfortable surroundings.

I have never seen anything to commend in the annoying restraints imposed by some surgeons on their cataract patients. I know that some are so fearful of jolts and the displacement of the eye-contents that they insist on operating upon patients in the beds in which they expect them to remain, so that the contents of the eye operated upon may not be disturbed by any movements of the body. I have experienced too much inconvenience from bed operations and defective light to continue this bad method, which I have long since discarded. The luxury of an operating-table of proper construction and height, placed where the full light of a large window will fall directly on the face of the patient, will enable the surgeon, placed at his ease, to manipulate so much more skilfully that the patient will therefrom derive much more advantage than he can possibly lose in going from the operating-table to the bed. When in bed, the petty annoyances inflicted by an over-careful surgeon are enough to start a whole train of nervous symptoms in the patient. Here are some of the orders which I have heard given: First, You must lie on your back, and on no condition turn on either side. Now and then a patient bolder than the rest will expostulate, with the statement that they have never been able to sleep upon their backs. The order becomes then the more imperative: You now must, or you will jeopardize the success of the operation. Second order, You must keep quiet and not talk to any one, conversation will excite you. Third order, You must eat nothing for twenty-four hours, for the use of the jaws in chewing food will be very detrimental by interfering with the quiet of the eye; you can have liquid food, but no solid food. Fourth order, You must not sit up in bed to take food during the first few days of treatment, but lying quietly on your back, must suck up the fluid nourishment by a tube. Fifth order, Under no condition must you get out of bed; for all calls of nature the bed-pan must be used, the patient lying down on his back. Sixth order refers to the fact that the eyes must not be touched, and therefore, for fear that an accident might happen during sleep, a band is secured to each wrist and tied loosely behind the back of the recumbent patient, or, as the arms lie on each side of the body, the free end of the night-shirt sleeve is sewed to the body of the shirt as a surety against any accidental movement.

My cataract extractions now number considerably over one thousand, and I take great pleasure in saying that these restrictions, which I have heard given to the patients of others, I have never practised, and yet my per cent. of successes are fully as good as those of my over-cautious surgical friends.

I desire to make the days of confining treatment pass by with as little annoyance to the patient as possible. When put to bed, patients are allowed to lie in any position which comfort induces them to take; to converse when they please; to get out of bed for all calls of nature; to sit up when taking food, and to eat whatever they know from experience will not disagree with them. After the second day they may sit up, if the bed is found irksome. When the adhesive straps are removed, on the sixth day, the freedom of the room is allowed. In a very few days afterward the chamber-door is thrown open, and the patient has the liberty of the house.

The following cases, recently operated upon and treated by the light dressings, and not in dark rooms, will illustrate the new and very much improved method of treating cataract cases:

Case I. Mr. McD——, [illegible], in failing health, has been blind in the left eye for over one year, and is losing sight in the right. Examination discovered a fully matured cataract, with good light perception, in the left eye, and striations in the right lens. Left opaque lens removed under cocaine, May 10, 1886. Operation smooth, leaving a clear pupil. Both eyes closed by isinglass plaster; patient walked from the operating table to the contiguous ward, and was there put to bed.

Second day.—Patient had been awakened at night by some pain in the eye, but now feels very comfortable. Straps adhering well, with no moisture about them. No treatment suggested by her condition.

Third day.—Has had no pain since the last visit. Is not inconvenienced by the light of the ward, in which the windows are screened by blue shades. Adhesive straps firmly adherent. No treatment.

Fourth day.—Feels perfectly comfortable, even when the shade was raised from the window to obtain a more perfect examination of the condition of the plasters. A drop of the one per cent. atropia solution was put near the inner canthus, and was soon felt in the eye under the adhesive strap, which was not disturbed. No treatment beyond the application of the eye-drop. Patient was allowed to get up if she desired to do so.

Fifth day.—Found the patient dressed and sitting up. She was in every way comfortable. The adhesive straps were so dry, indicating no eye irritation whatever, that I ventured to remove them without moistening them. The eyes opened at once, and bore the examination and the light of the room without any lachrymation. I was astonished at the small degree of hyperæmia. The appearance of the conjunctiva was as I had seen it in the most successful cases three weeks after extraction. A drop of atropia was applied, and the eyes left without further treatment or protection. No smoked glasses.

Sixth day.—The patient had suffered no inconvenience whatever from the exposure of yesterday and to-day. Eyes not watering. The light of the room well borne.

Seventh to fourteenth days were all repetitions of each other. The operated eye acquired strength, so that by the end of the second week she could go about the house and look out the open window into the sunny street. On this day she was dismissed from the hospital, with instructions to wear a smoked glass when out of doors, but not while in the house.

This was my first case of cataract extraction treated in a light room with a transparent eye-retentive dressing, and the experiment delighted me in the rapidity of the convalescence and the perfect results secured.

Case II.—Joseph R——, aged sixty-one. Left eye operated upon for cataract six years since; pupil so drawn up by the corneal cicatrix that he can only count fingers with this eye. The right eye has still useful vision.

May 10th.—Under cocaine a large iridectomy downward was made. This eye was closed by the broad adhesive strip; the other good eye being left open. He jumped from the table with a jolt, not intended, and walked unaided to the third-story ward. This case was treated throughout as a peripatetic, with the exception of keeping him in bed the day of operation. On the day after the operation I found him dressed, and walking about the ward. He had suffered some pain in the night, but at the time of visit (2 P.M.) felt perfectly com-

fortable. Atropia drops were ordered to be applied daily without removing the dressing.

Fifth day.—Finding the patient going in and out of the ward without any inconvenience whatever, I removed the strap, leaving the eye free, and without smoked glasses. In the conjunctiva there was very little injection, and there was no lachrymation.

This patient could have been discharged from the hospital at the end of the first week, as he stood the ordinary light of the house without annoyance. He was kept a few days longer for inspection, and was discharged on the twelfth day, putting on smoked glasses for the first time when he went out into the sunlight.

Case III.—Anna S——, aged sixty; double glaucoma with tension + 2; sight steadily deteriorating; counts fingers at four feet; deeply cupped disks; has an old corneal cloud in each eye which necessitated a downward iridectomy in the left, and upward in the right eye. These operations were performed May 11th, and both eyes were closed with adhesive plaster; patient walked up to the fourth story and was put to bed.

Second day.—Patient had pain during the night, but was now comfortable. Straps adhering well.

Third day.—No pain; being cloudy, the patient was not inconvenienced by the light of the room with shades lifted from the windows.

Fourth day.—Patient perfectly comfortable; no treatment.

Sixth day.—Adhesive straps removed. Patient not inconvenienced by the light of the room with shades down. Eyes show very little hyperæmia.

The continued convalescence in this patient was steady, and she was discharged from the hospital on the eighteenth day without the necessity of using smoked glasses at any time.

Case IV.—John D——, aged fifty. In pulling up a piece of carpet had his left eye perforated by the point of a tack, which entered near the lower corneal margin, perforated the iris, and must have injured the lens, because it slowly became cataractous after the injury. The lens shows plainly striations as an indication of its slow clouding. He has good light perception, and no pain in it. The appearance of the lens is rather from an idiopathic than from a traumatic origin.

May 13th.—Smooth extraction was made under cocaine, and both eyes were closed by adhesive straps. The patient walked up from the operating-room to his chamber in the fourth story, and was put to bed.

Second day.—Found the patient dressed, and sitting on his bed. He had had no pain whatever during the night, and had felt so very well that he saw no reason why he should remain in bed. No treatment.

Third day.—Patient has been up all day, feeling perfectly well; adhesive plasters dry, showing no eye irritation. No treatment.

Fourth day.—Patient continues well. A drop of atropia put at the inner canthus.

Fifth day.—Straps found loose from both eyes. Had suffered no inconvenience. Straps were moistened and reapplied. No treatment.

Sixth day.—Both straps were finally removed, and eye inspected. Very little redness was seen, and no watering during the examination. Eyes left open, unprotected, in the comfortable and moderate light of the chamber.

Eighth day.—As the patient could stand the light of the house without discomfort, he was allowed by the resident physician to go out at midday to a neighboring barber-shop to be shaved, using as a protection smoked glass.

Ninth day.—No inconvenience nor discomfort from the unusual exposure of yesterday.

Fourteenth day.—Patient discharged to-day with a strong, excellent eye. There is some capsular deposits, but in the centre of this is a clear, sharply defined opening, through which excellent vision is obtained. In going out of the hospital he was advised to use smoked glass on the street.

He called at my office five days after he left the hospital. He had on no smoked glasses, and said that he had not put on any on leaving the hospital, as he did not feel the want of them, and had suffered no inconvenience from the sunlight of the street.

Case V.—Laura W——, aged forty, has been blind more or less for twenty years. One year since she had a cataractous lens removed successfully from the right eye. Although she can get about with this eye, vision is very imperfect, owing to a very pronounced conicity of the cornea. In the left eye the conicity is by no means so marked. The lens in this eye is opaque and white, with good light perception, but no choroidal reflex upon ophthalmic examination. The lens of this eye was removed, under the anæsthetic effects of cocaine, on May 13th. After all the lens substance had been forced out by pressure, a thickened capsule remained, which was drawn out by forceps, leaving a brilliant, clear pupil. Both eyes were closed by isinglass plaster, atropia drops having been previously instilled. She walked from the operating-room to her bed in the fourth story.

Second day.—Complained of much pain during the night, and still has some. The adhesive straps are not wetted, showing but little lachrymation, and are, therefore, not disturbed.

Third day.—Patient has passed a good night, and all pain has disappeared.

Fourth day.—Patient very comfortable and straps well adherent; a few drops of atropia were put near the inner canthus.

Sixth day.—Patient having had no trouble the straps were removed; the eye was found strong for moderate light, and with very little hyperæmia.

Tenth day.—Patient is moving about the house with no inconvenience from light; she has a clear pupil and excellent vision.

Eighteenth day.—Patient returned to her distant home to-day, having had a perfect result from the cataract extraction. She was advised to use smoked glasses for out-of-doors, and not for the house; but as she can face the sunlight of the window she does not seem to think the protection necessary.

Case VI.—Mrs. B——, aged fifty; cataract fully formed in right eye; forming in left; general health good; had cataract extracted to-day, May 15th, under cocaine. The operation was painless and smooth, leaving clear pupil and the ready counting of fingers. Atropia, four-grain solution, was instilled, and both eyes were strapped. She walked to her room on the same floor as the operating-room, and was put to bed.

Second day.—Has had no pain, and is perfectly comfortable.

Third and fourth days were duplicates of the second, painless and comfortable. An atropia drop was used each day without disturbing the straps, allowing it to be sucked along the lashes by capillary action.

Fifth day.—The patient having had no pain whatever from the day of operation, I anticipated the removal of the dressings by one day, and removed the straps. The exposure of the light of the chamber caused no uneasiness or lachrymation; there was very little conjunctival injection, and objects could be very readily recognized.

Sixth day.—No trouble; patient walks about the room without inconvenience.

Ninth day.—Patient suffers so little inconvenience that she has the freedom of the house without glasses.

Twelfth day.—With $2\frac{1}{2}$ + lens patient reads brilliant type.

Fifteenth day.—Patient returned to her home using a pair of light blue glasses as her sole protection from strong light.

Case VII.—Miss O——, aged sixty-two, was born with small zonal cataracts, and therefore has never en-

joyed good sight. They have been slowly developing, so that for twenty-three years she has not been able to read the largest book-type. Now she counts fingers with each eye at four feet. On ophthalmoscopic examination choroidal reflex is seen in each eye. The deposit in the lens seems chiefly at the central region, with some clear substance in the anterior and marginal layers. She had travelled five hundred miles, and was very anxious to be operated upon, yet the cataracts were not sufficiently matured. She accepted the proposition and the risk of having one of them ripened by being needled under cocaine, on May 15th. This eye alone was closed by adhesive plaster, after being well soaked with an atropia solution.

Second day.—No trouble whatever from the corneal and lens puncture of yesterday; applied the atropia solution.

Third day.—Removed the plaster; eye not reddened, but the effect of needle-puncture upon the lens very perceptible; pupil well dilated from atropia.

Fourth day.—Lens ripe for extraction. Operation on this left eye was smooth, and fingers were readily counted after the extraction; atropia applied, and both eyes strapped; patient walked from operating-table to fourth story, and was put to bed.

Fifth day from needle operation, and second day after extraction.—Patient had some pain in the night, but the eye feels easy now; straps not moistened from any lachrymation; atropia drop put at inner canthus

Third day of extraction.—Patient very comfortable; the light of the room is sufficient to allow her sister to read to her and write for her; no treatment.

Fourth day.—A duplicate of yesterday; no discomfort of any kind, and no treatment required beyond the atropia drop.

Fifth day.—Patient so perfectly comfortable, and adhesive straps so dry and undisturbed, that I ventured to remove them. I adjusted the curtain of the room to exclude a little of the light, not that the light was complained of, but on account of my own timidity, as the eye had undergone two operations at a short interval.

Sixth day.—Patient had some pain in the night, and found the eyelids glued up this morning; they were washed open with warm water. Since awaking they have given no pain, yet there is a slight tendency to lachrymation; the one per cent. of atropia was applied, but the light of the room was not reduced.

Seventh day.—Eye strong, no more watering nor discomfort. Patient moves about her room with freedom.

Tenth day.—The eye looked so remarkably well today, so free from congestion, that I tested vision, and found that with a lens she could read the title-page of a book, the first letters she has seen for twenty-three years. The ordinary light of the room when the shade was run up caused no inconvenience.

Thirteenth day.—Patient ready for dismissal. With cataract glasses and without the protection of smoked glasses she can look into the sunny street and read signs on the opposite houses. There is no congestion of any kind in the eye operated upon. The appearance of the conjunctiva is as white in this eye as in the other, which has not been disturbed. In each it is perfectly normal.

Case VIII.—M. G——, aged eighty-eight, and very feeble, has had cataracts in each eye fully matured for some time. He is anxious to see again and has sought my advice. I recommended an operation because there was no risk to life, and if the operation failed he could be no worse off than at present. May 19th, under cocaine, the lens was removed from the right eye, both were closed by adhesive strips, and the patient walked to his bed in the fourth story. As he was very feeble, and had been annoyed by a bad cough for one year, he was kept in bed till the sixth day. Each day he reported no trouble, no eye uneasiness of any kind, and the clean straps well adherent to the lids were an endorsement of his statements. His cough was controlled by ipecac and opium.

Sixth day.—When the straps were taken off he saw my face at once, in evidence that the operation had been successful. The eye was not injected to any extent, and as there had been no mattering, the lashes were not glued together to interfere with immediate opening. Atropia solution applied.

Seventh day.—The eye caused him some uneasiness last night, and is watering a little to-day. Atropia drops were ordered, but no diminution of the light in his chamber. His vision was clearer, notwithstanding the discomfort of the preceding night.

Eighth day.—The lids of both eyes show some slight hyperæmia and some sticking together this morning; both eyes equally affected and with slight conjunctivitis.

Fourteenth day.—Patient left the hospital to-day with good sight. There is still some little conjunctivitis in each, quite as much in the eye not operated upon as in the one from which the lens was removed. It gives him but very little inconvenience. He was advised to put on smoked glasses for the street.

Case IX.—Elizabeth S——, aged fifty-one, had had cataract extracted from the left eye six months since. Cataract forming in the right. Good vision was prevented in the eye from which the lens was removed by the presence of a thickened capsule. The pupil was free, and expanded well under atropia. May 20th, under cocaine I opened the cornea from above, and with Mathieu's iris forceps extracted all the capsule. It came out *en masse* and left a brilliant pupil. Atropia was applied, and both eyes closed by isinglass plaster. She walked to her bed in the fourth story of the hospital.

Second day.—Had had some pain during the night but was now free. Straps dry and adhering.

Third day.—Very comfortable; atropia drop.

Fourth day.—Found the straps curling up. Removed them and applied fresh ones, also used the atropia drop.

Fifth day.—Removed isinglass plasters from each eye. The eye shows no irritation from the shaded light of the room; atropia instillation.

Sixth day.—Eye strong, no pain, very little injection.

Eighth day.—Patient has the freedom of the house, and goes about without inconvenience and without smoked glasses, and she is ready to leave the hospital.

During the months of May and June, 21 cataract extractions and 4 iridectomies have been treated by this new method at the Presbyterian Eye and Ear Charity Hospital of Baltimore. The progress of all these cases has been so satisfactory that I have every reason to expect a continuance of these good results. From my experience, I think that I can confidently say that I will not again have use for compresses, bandages, and dark rooms, as elements of treatment in cataract extraction.

Extract of Calabar Bean in Epilepsy.—Dr. Rusche recommends the exhibition of calabar bean in epilepsy and allied affections, and says he has found it to render great service in cases in which the bromides and atropine have been ineffectual (*Deutsche Medicinal-Zeitung*, May 10, 1886). He notes the curious circumstance that better results are obtained by alternately increasing and diminishing doses than when the same quantity is given continuously. The drug is to be given in the following preparation: Extract of calabar bean, 7½ grains; spirits of sulphuric ether, 75 minims; peppermint-water, 5 drachms. Dose: 5 to 10 drops for children, 8 to 15 drops for adults, three times a day. The smaller dose is commenced with the first day, and one drop added each day until the maximum is obtained, and then the quantity is diminished by a drop each day until the minimum is reached. The writer reports a number of cases in which excellent results were obtained.

Professor von Arlt, the well-known ophthalmologist of Vienna, recently fell in the street and sustained a fracture of the left humerus.

Clinical Department.

TWO CASES OF SPASMODIC STRICTURE OF THE URETHRA RELIEVED BY FREE MEATOTOMY.

HOBART CHEESMAN, A.M., M.D., New York, Clinical Assistant for Venereal Diseases at the New York Post-Graduate School and Hospital, sends us the following: "The following two cases of spasmodic stricture of the urethra seem to me excellent examples of a class of strictures supposed to be due to reflex irritation. In these particular cases the reflex evidently had its origin in the irritation caused by a too narrow meatus urinarius. Why a meatus of a size which in many persons is seen to exist without causing irritation or exciting any symptoms, should occasionally, in an individual, give rise to very evident and serious symptoms, is a problem which had better be left to the tender care of more profound intellects. That such is the case experience supplies abundant proof. It should not, however, be inferred from this that every patient suffering from deep spasmodic stricture, and who has a smallish meatus, will be cured by incising it freely. There are reflexes arising from various well-known sources, other than the meatus, capable of producing the same result. A small meatus, when encountered in such cases, should be treated with only as much respect, and as great consideration, as a full and critical examination of all the facts in evidence justify. Therefore I may not be understood to advocate by these cases meatotomy for every case that presents with a meatus too small to admit the passage of a number 32 or 34 F. bougie à boule. But what is aimed at is to call attention to the fact that, perhaps oftener than is generally admitted, the free incision of a smallest meatus—and that, too, even when there has been no inflammatory process at work to cause unnatural narrowing of it—will remove grave and, may be, persistent symptoms as by magic. I think this is well shown in the following cases, which are presented, not as being unique, but as being remarkably good illustrations of the type.

"CASE I.—H. M——, American, aged twenty, theological student, July 15th. Has had various nervous symptoms for ten days, such as pricking sensation over the surface of the body, and cold and blue extremities, and for thirty-six hours has been unable to pass his urine, while at stool even; but it has been drawn by an elastic catheter. For three or four days has had diarrhœa and occasional vomiting. Denies having had any venereal disease. Examination shows a rather small meatus urinarius, admitting snugly through it No. 23 F. steel sound, which also passes readily into the bladder, but it is moderately hugged in the deep portion of the urethra. The urine is drawn with a 20 F. gum elastic catheter. Examination of the urine shows nothing abnormal except a little albumen. The diarrhœa and vomiting being speedily controlled, treatment was directed to the nervous symptoms and the retention of urine. A spinal ice-bag soon restored the circulation to the extremities, and under bromide and quinine as a tonic the other nervous symptoms abated; but the retention of urine continued unaffected, although all the usual means of relief were employed. On July 26th, eleven days after my first attendance, not a drop of urine having passed his urethra, even when at stool, except per catheterem, I incised the meatus so as to admit the passage through it of No. 30 F. bougie-à-boule. No. 28 F. bougie-à-boule could then be passed down to the triangular ligament, and withdrawn without detecting stricture.

"The next day the patient passed urine while at stool, but was unable to start the stream at other times until on the 29th, when he passed it freely and regularly, and continued to do so unimpeded thereafter. On September 28th, two months later, he was still suffering intermittently from the nervous symptoms, but had had no further difficulty in passing urine. I have not seen him since that date.

"CASE II.—S. W——, American, aged fifty-eight, marketman. Seen for the first time on October 3d. Had gonorrhœa several times, the last attack occurring over twenty-five years ago. Treated each time by injections. Ever since the last attack has suffered more or less from frequent micturition, and the stream has been small; never suffered much pain. For the year past has had to get up at night every two hours to urinate, and during much of this period the act has been accomplished only after much straining, and by driblets. This is his present condition. Examination of urine shows nothing abnormal, except a moderate amount of mucus.

"Examination of the urethra on October 11th: Meatus admits snugly No. 22 F. steel sound, which is arrested at six inches. No. 18 F. is arrested at seven inches. After many futile efforts to cause an instrument to enter the bladder, finally a fine whalebone was made to enter by being passed down by the side of a No. 4 F. elastic bougie. On the 14th, and a third time on the 16th, the same trials were made to enter the bladder, but with no better success; the same fine whalebone being the only instrument that could be made to enter, although the attempt was made by two surgeons besides myself. No. 18 F. steel sound was resisted at six inches, but could be urged on an inch deeper, where it was firmly grasped and effectually arrested. The meatus was then cut (on October 16th), so as to admit the passage of No. 34 F. steel sound. No. 18 F. steel sound then passed, with very little urging, through the deep stricture and entered the bladder, followed, in course, by Nos. 22, 24, and 27 F. No further trial was then made. The next day Nos. 27 and 29 F. steel sound passed easily, and entered the bladder; the patient declared that he had got up but twice during the past night to urinate. It had been his custom to get up five or six times. October 27th, Nos. 27 and 30 F. sounds passed easily, but some resiliency of the deep urethra persists, as shown by its continuing to grasp the sound slightly. The patient continues, since the operation, to pass his water about every four hours. On October 28th, after holding it three hours, it was passed in my presence. The stream started freely, was full and strong, and uninterrupted; in other words, a perfectly normal one. He remained under observation for six weeks after this date, but had no more trouble in passing his urine. Since then I have not seen him."

A CASE OF RUMINATION.

DR. W. A. HUBBARD, of Bloomfield, N. Y., writes: "In a recent editorial in THE RECORD on 'Rumination in Man,' you say that it 'is not unlikely that the affection may be beneficial rather than otherwise to its subjects, and the food, if not subjected to a second mastication and admixture with saliva, might put too great a tax on the stomach and thus excite gastric troubles.' I take from my note-book the history of the following case, which is not only an addition to the small number of recorded cases of the kind, but also a verification of your conjecture relative to the gastric disturbance that might occur in case of its suppression: D. L——, farmer, aged thirty-five, of Irish descent, consulted me in April, 1885, for, as he expressed it, the restoration of his 'lost cud.' He had contracted the habit at a time beyond his recollection, and had had no intermission in its practice until one month previously, when it had suddenly ceased and was immediately followed by dyspeptic symptoms. He had constant nausea, although vomiting he found to be impossible. It had been his habit to swallow his food hurriedly, with as little mastication as possible, and retire from his family or associates, after which the process of regurgitation immediately began and continued for twenty or thirty minutes. This retirement was necessary for the perfect digestion of the food. He had been an enormous eater, and his health had been perfect until the

sudden stop in this peculiar physiological process occurred. I informed him that his request was undoubtedly unique, and suggested the thorough mastication of his food previous to deglutition; but this, owing to habit and forgetfulness, seems impossible, and he still continues dyspeptic, despite the usual remedies given to aid digestion, and lives in the expectation that his habit will return as suddenly as it left him."

A CASE OF HYDROMETRIA.

Dr. E. J. Cowden, of North Warren, Pa., reports the following case: On December 4th he was called to see a young lady, single, aged nineteen, who had always enjoyed good health up to that time. She began to menstruate at thirteen, and had been regular, her last period having been on November 1st. She took a severe cold in the latter part of this month, and was found to be suffering from the usual symptoms of suppression. Various emmenagogues, including permanganate of potassium, were given from time to time without effect. In the latter part of February it was noticed that the abdomen was gradually increasing in size, and this continued until she began to attract the attention of the neighbors. Dr. Cowden made a careful examination, but could detect nothing that would warrant a diagnosis of pregnancy. The womb was large and distinct fluctuation could be obtained on palpation, but no passive movements could be felt, neither could ballottement be elicited. There had been no morning-sickness, and the breasts were not changed. The patient was also examined by Dr. John Curwin, who confirmed the writer's negative diagnosis, and by one of the most prominent surgeons of Northwestern Pennsylvania, who pronounced the case one of pregnancy at about the sixth month. From this time the patient lost flesh very rapidly, and the abdomen continued to enlarge. Dr. Cowden again made an examination, but could detect nothing but fluid. On June 13th, as the patient arose in the morning, there was a gush of colorless fluid nearly filling the chamber-vessel. A slight flow continued until the second morning following, when about nine quarts of the same colorless fluid came away in a torrent. The uterus rapidly descended into the pelvic cavity, and the patient's health is now gradually improving and recovery is hoped for.

TREATMENT OF ASPHYXIA OF THE NEWBORN.

Dr. J. C. Roberts, of Pulaski, Tenn., writes that he was struck with the description given by Dr. L. N. Sharp, in The Record of July 3d, of his method of resuscitating asphyxiated infants; and, while yielding to Dr. Sharp the priority of publication, he desires to add his own testimony as to the value of the procedure. He was called one night in consultation with his brother to a case of twin labor. The first child had been born some two or three hours, but the second was presenting by the shoulder and a loop of the funis had fallen down. As there was no perceptible pulsation in the cord, the heart-sounds could not be heard, and the movements of the child had ceased, it was supposed that it was dead. The woman was brought under the influence of chloroform, turning was performed, and the child delivered with the forceps. The ordinary methods of resuscitation were employed, but the child gave only one or two spasmodic gasps and then apparently died. Dr. Roberts continues: "The thought struck me that, as we had used chloroform, I would as a last effort employ the treatment for threatened death from this anæsthetic. I seized the child by the feet and suspended it perpendicularly, and, to my astonishment, as soon as the blood gravitated to the head, which was made apparent by the change of color in the face, the child at once gasped. The second gasp was followed by a loud and continued crying, and the life was saved. Since that time I have resorted to the same plan in several cases of asphyxia of the newborn, with immediate and happy results."

A WANDERING TAPEWORM.

Dr. W. Davidson Bidwell, of Leavenworth, Kan., writes that a short time since a lady from the country brought him her boy, three years of age, with the account that he had passed several pieces of tapeworm during the past two months, and had become feverish and sickly. At bedtime a dose of castor-oil was given the boy, and the next morning fifteen minims of oleoresin of male fern in five-minim capsules, at intervals of one hour, another dose of oil being given in the afternoon. That evening the child passed a very long worm. A piece about a yard long became detached from the rest, and this piece, which tapered nearly to a point at one end, moved off, pointed end first, across the floor some six feet, and had climbed up the smooth side of the wall a distance of two and a half feet before it was discovered. The rest of the worm was noticed to wriggle some, but did not attempt to crawl away. During the two months that the child was passing portions of tapeworm large numbers of pinworms were noticed almost daily in the evacuations. Dr. Bidwell asks whether such motions of a tapeworm outside of the body are often observed, and also whether it is common for the two kinds of worms to be associated?

ABORTIVE TREATMENT OF MAMMARY ABSCESS.

Dr. Llewellyn Eliot, of Washington, D. C., sends us the following: "About fifteen years ago I witnessed the beneficial effects of the free application of spirits of turpentine to abscesses and whitlows in their early stages. The result in each case in which such applications were employed was a drying up and disappearance of all traces of inflammatory or suppurative processes. From the earliest years of my professional life this has been a routine treatment with me, and, arguing from analogy, it has been adopted in cases of mammary abscess when seen in its incipiency. The only disadvantage attending this treatment is the odor of the turpentine, which is of no importance when contrasted with the intense pain, sleepless nights, and suffering accompanying suppuration of the gland.

"If, upon the discovery of a drawing pain upon suckling, or a tender, hard spot in any part of the gland, the part be bathed with the spirits of turpentine, and then covered with a cloth, rag, or piece of flannel saturated with the same, we may, as a rule, look for the disappearance of the hardness, the tenderness, and all other uneasiness attending this troublesome affection, in the course of two or, at the most, three days. During the course of such a treatment the child may be nursed from the affected breast, but not as frequently as from the well one. It is hardly necessary to say that all traces of turpentine should be washed away before such nursing. The amount of milk secreted has never appeared lessened in the cases observed, nor have any of the ill results of the continued use of turpentine followed either in the mother or in the child.

"Whether this manner of dealing with this affection be in general use or not cannot be said, still there is no mention of it in many of the recent text-books on obstetrics. It is not claimed to be infallible, but its application will be attended with no bad results even if it be unsuccessful. Strapping, pressure, rest, applications of belladonna and soap-liniment, and the continuous application of an ice-bag, are among the various modes of treatment employed, but my faith now centres around the application of turpentine as an abortive of mammary abscess."

Progress of Medical Science.

Ulcerative Endocarditis.—In an elaborate study of ulcerative endocarditis, in the July number of *The American Journal of the Medical Sciences*, Dr. Byrom Bramwell records fourteen cases in all of which the aortic valve was affected, either alone or in combination, the mitral in six, and the tricuspid in one. In two of the three cases in which well-marked acute croupous pneumonia was present, he detected micrococci in the exudation filling the air-cells of the lung, but he failed to satisfy himself that they were identical with the micrococci in the cardiac vegetations. The frequent association of acute croupous pneumonia with ulcerative endocarditis is a point of great interest, but Dr. Bramwell's observations on this point have not been sufficiently extensive to enable him to form a satisfactory judgment; but his pathological experience clearly shows that during certain seasons acute croupous pneumonia and ulcerative endocarditis are apt to prevail. The detection of micrococci in the inflamed cerebral meninges, and in the vessels and substance of the cerebral cortex, and the presence of disseminated patches of cerebritis and acute cerebral softening, are very interesting; and afford a satisfactory explanation of the nervous symptoms which are so prominent in some cases of the disease. Mr. A. W. Hare, in response to Dr. Bramwell's request, undertook an experimental investigation to determine the relationship of ulcerative endocarditis to other infective conditions. The results which he obtained, and which are detailed in the paper, are, for the most part, negative.

The Treatment of Freckles.—The following procedure is recommended by Dr. Halkin: The skin being washed and dried is put on the stretch with two fingers of the left hand, and a drop of carbolic acid is applied exactly over the patch. When it dries the operation is completed. The skin becomes white, and the slight sensation of burning disappears in a few minutes. The thin crust which forms after the cauterization should not be disturbed; it detaches itself spontaneously in eight or ten days, leaving a rosy coloration, which is soon replaced by the normal color of the skin.—*American Practitioner and News*

The Function of the Recurrent Laryngeal Nerve.—The mode of action of this nerve, supplying muscles so important in their use, both phonatory and respiratory, and yet so opposed in their action, is a much mooted point upon which Dr. Frank Donaldson, Jr., endeavors to throw additional light, in an experimental paper in *The American Journal of the Medical Sciences* for July, 1886. The recurrent laryngeal nerve supplies all the intrinsic muscles of the larynx, with the exception of the crico-thyroid, and it is chiefly a motor nerve. It is a physiological fact that the internal thyro-arytenoids, the lateral crico-arytenoids, and the transverse arytenoids are the adductor (the phonatory) muscles of the larynx, and that the posterior crico-arytenoids are the abductor (the respiratory) muscles of that organ, and all these muscles receive their nerve supply from the recurrent laryngeal. This nerve, then, must contain two sets of fibres, which innervate muscles of separate and distinct functions. How, and under what circumstances, does the constrictor or respiratory function of this nerve assert itself, is the important question to be answered. As the result of his experimentation and study, Dr. Donaldson explains the innervation of the larynx somewhat as follows: Breathing is an involuntary act, though the diaphragm and all the other muscles employed in respiration are voluntary muscles; and though respiration may be modified within very wide limits by the will, yet we habitually breathe without the intervention of the will. The larynx is an essential part of the respiratory apparatus, and is immediately connected with, and must receive impulses from, the respiratory centre in the medulla, and its respiratory function is the most important; for the purpose of preserving life the glottis must be kept open, and so we find that the cords, even in normal breathing, at each inspiration are pulled slightly away from their apparently normal position between extreme abduction and extreme adduction. The fact that in deep narcosis the cords are pulled widely apart, would seem to show that stronger stimuli than usual are proceeding from the respiratory centre to the abductor muscles; for in all deep narcosis the tendency is toward dyspnœa, and always in this condition normal respiratory muscles are called into greater play. The constrictors of the larynx are apparently always in a state of partial tonic contraction, and ready for use at any moment; and the respiratory function of the larynx being for the moment in abeyance, the protective or constrictor function of that organ asserts itself. Again, it is well known that great changes can be brought about in the respiratory movements by the will; while, on the other hand, the respiratory centre is the one most frequently affected by nervous impulses from various quarters. He thinks that his experiments support the supposition that both the respiratory and constrictor (or protective) functions of the glottis are governed by those laws which govern the rest of the respiratory apparatus. The larynx, being part of the general respiratory apparatus, its inspiratory and expiratory (constricting) functions are under the same nerve control as the rest of the organs concerned in inspiration, and under no circumstances are these functions suspended. There seems to be a similarity between the nerve fibres of the recurrent and those of the pneumogastric; the two sets of fibres of the recurrent supply opposite sets of muscles, and may be likened to the two kinds of nerve fibres composing the pneumogastric—the one answering to less, the other to stronger stimuli.

Connection Between Scarlet Fever and Heart Disease.—The following are the conclusions formulated by Dr. Henry Ashby, in a lecture on this subject published in *The Lancet* of May 22, 1886: 1. In uncomplicated cases of scarlet fever, lesions of the heart are very rare. 2. Endocarditis is quite exceptional in scarlatinal synovitis; pericarditis occurs more frequently. 3. Acute or subacute rheumatism occasionally supervenes during convalescence from scarlet fever; an attack of scarlet fever may also be the exciting cause of a relapse; in such attacks peri-endocarditis is frequent. 4. Peri-endocarditis occasionally occurs in scarlatinal pyæmia. 5. Dilatation without valvular disease very frequently occurs in scarlatinal nephritis; peri-endocarditis and embolism are by no means uncommon.

Paraplegia and Anæsthesia of the Legs.—At a recent meeting of the Midland Medical Society, Dr. Suckling read a paper on certain forms of paralysis and their treatment by faith-cure. He showed a woman who had been sent to him suffering from paraplegia and anæsthesia of the legs, following a fall five months previously. She was of the neurotic type; cheerful, intelligent, energetic, industrious, and eager to get well. After being informed that the application of electricity would cure her, faradization was employed, resulting in recovery.

Incarcerated Umbilical Hernia.—Although umbilical hernia is not an affair of rare occurrence, the incarceration of the intestine in this situation is very uncommon. Dr. F. J. Zielewicz reports, in the *Centralblatt für Chirurgie* of June 5, 1886, the case of a child, eight months old, well nourished and healthy, who was noticed to have a small umbilical hernia shortly after birth. This was treated by a bandage applied by the midwife. One day, while the child was crying, the hernial tumor suddenly increased in size. The mother was unable to replace the intestine; the child refused to eat; could pass nothing at stool, and began to sink rapidly. The next

day the little patient vomited several times, and the abdomen grew very hard and tense. The tumor was the size of a pigeon's egg, of a bluish color, and was irreducible. Herniotomy was performed, the skin over the tumor was incised, and the gut was released only after three incisions had been made in the borders of the ring. The edges of the skin, together with the hernial sac, were brought together and held in apposition by a number of close sutures, and the wound was dressed antiseptically. The child made a rapid recovery, and the hernia was radically cured. Another case is reported by Dr. Emerich Thoman, in the *Allgemeine Wiener Medizinische Zeitung*, No. 20, 1886. The patient, a married woman, forty-two years of age, had noticed a prominence of the umbilicus since the birth of her last child, twelve years before. One day, after exposure in a cold rain, she had a chill, but being very hungry ate heartly of solid food. Soon after she began to suffer from colicky pains, nausea, vomiting, and chilliness. These symptoms increased in intensity for four days, during which time there had been no movement from the bowlels. The writer first saw the patient at this time, and found a small umbilical hernia, the parts about the ring being swollen and inflamed. He succeeded in reducing the hernia by gentle taxis, and the patient immediately expressed herself as greatly relieved. Shortly afterward the bowels acted, the symptoms of strangulation subsided, and the woman felt a desire for food, and slept for the first time in four days. There was still, however, considerable inflammation in the neighborhood of the ring, and the patient was ordered to keep perfectly quiet in bed, and to take none but liquid food. She felt so well, however, that she disobeyed these injunctions and got up to wash and go to stool. Almost immediately symptoms of severe general peritonitis set in, the patient went into a collapse and died within a few hours. Dr. Thoman believed that the peritonitis was caused by perforation. The inflammation occurring during the period of incarceration of the hernia had given rise to adhesions, and the intestine being softened the movements of the patient had caused the rupture of the walls of the gut, and gas and fecal matters then escaped into the peritoneal cavity.

Myriapods in the Intestine.—Dr. Rooms reports the case of a boy, eleven years of age, who suffered from nervousness, a feeling of peculiar and painful movements in the abdomen, became very pale, and acquired a dislike to milk and fatty articles of diet. A dose of some ordinary anthelmintic caused the expulsion of some ascarides, but no improvement in the symptoms followed. The boy was much better in the winter, but the same symptoms made their appearance again the following summer. The same thing occurred the next year. One day the patient chanced to take, fasting, some juniper-juice with wormwood, and soon after discovered some live myriapods in the stools. A decoction of artemisia was now given as a medicine, and a number of the myriapods were expelled, and the boy became much better. The following summer the same symptoms reappeared. After a double dose of wormwood numbers of the myriapods were expelled at stool, and by vomiting, and from that time the boy remained well. Professor Plateau diagnosed the myriapod as *Iulus Londiniensis*, which sometimes lives in the intestine as a pseudo-parasite, its presence there coming probably from the eating of raw fruit.—*Centralblatt für klinische Medicin*, June 5, 1886.

A Rare Case of Hydrocele.—Dr. C. A. Dethlefsen reports the following case in the *Hospitals-Tidende* of June 9, 1886. He was consulted in November, 1882, by a man, thirty-four years of age, suffering from a hydrocele! The affection had begun twenty years before, without any apparent cause, by the appearance of a swelling in the left half of the scrotum. Some years later, while he was riding on a horse, considerable pressure being made on the tumor, he suddenly felt a sharp tearing pain shooting upward in the direction of the left inguinal canal; this soon subsided, however, and gave him no further trouble. The tumor then began to grow larger, and some time later a swelling was noticed in the abdomen. The latter caused him considerable inconvenience, and sometimes prevented him from working. He was treated for some time with external applications of iodine, but without success, the tumors in the scrotum and the abdomen both continuing to increase in size. Examination showed the left half of the scrotum distended by a smooth, translucent tumor, the size of a child's head, tapering upward into the inguinal canal. The abdomen was distended, and a hard, smooth tumor, reaching up an inch above the umbilicus, could be felt on palpation. The size and shape of the swelling suggested a gravid uterus at the seventh month. Percussion on the scrotum was followed by an impulse communicated to the hand placed over the abdominal tumor. The scrotal sac was laid open and a drainage-tube, about twelve inches in length, was passed up to the fundus of the abdominal sac. The latter was then washed out every few days with carbolized water, and gradually contracted until at the end of six or seven weeks it could be felt as a hard tumor, the size of a large hen's egg, lying against, and plugging up the internal inguinal ring. A few months later the patient again presented himself with a scrotal hernia. This could be reduced with great ease, and examination revealed the fact that the plug had disappeared from the entrance of the canal. In the scrotum, however, could be felt a rather firm mass, which the author supposed to be the shrivelled remains of the original sac, driven down by the hernia through the canal. A truss was applied, and the patient was dismissed in good condition. It would appear that the fluid was first effused within the tunica vaginalis testis, and the tumor, having attained a large size, had forced a passage, like a reversed, hernia, through the inguinal canal into the abdomen, where there was room for a further enormous development.

The Open Treatment of Abdominal Tumors with Fluid Contents.—Although a large proportion of abdominal and pelvic tumors with fluid contents are now curable by means of extirpation, there yet remain some which are not amenable to this mode of treatment. Among these are suppurating tumors of the mesentery; hæmatocele, resulting from pelvic peritonitis; cysts of the spleen, liver, and pancreas; dropsy of the gall-bladder, etc. Formerly such tumors were punctured, the cannula being left *in situ*. Dr. Péan claims (*Gazette des Hôpitaux*, No. 33, 1886) to have been the first to make a large incision into the sac and thoroughly empty it, thus promoting rapid healing and preventing septic infection. A free incision is made in the skin, the sac of the tumor is drawn out as far as may be, and, if possible, attached to the opening; the sac is then incised, emptied, disinfected, and a drainage-tube is inserted. In the last twenty-one years the writer has performed this operation fifty-seven times, and his experience has led him to regard it as the safest mode of treatment for such fluid tumors as cannot be extirpated, and far preferable to simple tapping and drainage.

Removal of a Sliver from the Eye by Suction.—Dr. R. E. Curran writes as follows in the *Southern California Practitioner* for May, 1886: A friend applied for relief the other day with "something in his eye," which amateur efforts had failed to find or remove. Reflected light showed a foreign body on the cornea, and a magnifying glass revealed the fact that a splinter of steel had penetrated the conjunctiva obliquely, and was entirely covered. Attempts to remove it with the spud were unsuccessful, and there was danger of perforating the cornea; but while applying solution of cocaine with dropping-tube the idea of *suction* was suggested, and covering the wound with the mouth of the dropping-tube, and with a gentle reverse motion of the bulb, I was happily successful in the first effort.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 31, 1886.

THE OUTCOME OF THE DISCUSSION BEFORE THE ACADEMY OF MEDICINE OF PARIS.

WE noticed in these columns some time ago the discussion which was then being carried on in the Paris Academy of Medicine, concerning the relationship of microorganisms to disease. The discussion is now closed, after having dragged along for upward of three months, and, as is usual in such contests, the participants occupy nearly the same position that they did at the outset. M. Peter and his followers regard the microbes of all shapes and sizes as innocent parasites, incapable of setting up diseased action in any of the tissues, while his opponents, who were largely in the majority, still hold to the new theories of the etiology of disease, and are in no way shaken in their belief by the arguments of their adversaries.

But while in the main the discussion was fruitless, except as it led to perhaps a rather clearer and fuller statement of the doctrines of leucomaines and microbes than we have yet had, it has nevertheless resulted in the development of a new theory, that of microzymes. The theory may be characterized as an attempt to reconcile the two antagonistic doctrines by a compromise. M. Béchamp was the engineer who endeavored to construct this *via media* over which the two armies, reunited under a common flag, might be made to pass. But we question whether this truce can be brought about.

The new theory, briefly stated, is as follows: Every cell, of whatever kind it may be, whether blood-corpuscle or epithelial cell, is made up of minute granules, as they appear under the microscope, which, while constituting the cell, or a part of it, are really independent entities. They are not destroyed with the cell, but remain and become developed and assume new forms and new characteristics, according to the varying circumstances under which they may chance to be placed. These developed forms are the microbes, and to the same forms in their chrysalis state, if we may be allowed the expression (the granules of which the cells are composed), M. Béchamp gives the name of microzymes. It depends entirely upon the conditions under which these granules begin their independent existence whether they become virulent or innocuous. When growing in certain media they are harmless, while at the same time they preserve their characteristics to such an extent as to enable them to make a sufficient impression upon their host to render him impervious to the attacks of their more dangerous cousins. In this way the author explains the principle of protective inoculations against disease. But the same microzymes, under other less favorable conditions, may assume most dangerous forms and become the direct exciting cause of morbid action.

This theory, like almost all theories when ably presented, possesses a certain fascination. It seems to fit, as it were, into various lacunæ which the other theories have left unfilled. But it has very weak points, and these, obviously, are the premises. The author must first prove to us that there are such things as microzymes, and then that they are capable of development into microbes. A committee has been appointed by the Academy of Medicine to examine into M. Béchamp's methods of research, and to settle the question of the existence of the mycrozyme, if it can. We shall do well to wait and learn what the committee has to say before we assume that these minute granules are the germs of pathological microorganisms.

THE TREATMENT OF ERYSIPELAS.

MANY and various are the methods which have from time to time been vaunted as specifics, or at least as invaluable aids, in the treatment of erysipelas. Of all these the antiseptic methods have found most favor in recent times. External applications of tar and of carbolic acid, subcutaneous injections of carbolic acid, and multiple incisions and scarifications, designed to permit of ready access of the antiseptic remedies to the diseased parts, may be mentioned as the most direct methods. Other and less disagreeable means of exhibiting antiseptics are through the stomach.

In the *Centralblatt für Chirurgie*, No. 19, 1886, Dr. Haberkorn speaks very highly of the internal administration of benzoate of sodium. He thinks this drug has been abandoned too rashly after the disappointment following its use in pulmonary phthisis, and believes that it is a very useful remedy in infectious diseases, more especially the exanthemata. He employs it in erysipelas in doses of from four to five drachms per diem, given in mucilaginous suspension or in seltzer water. In nearly every case in which the drug was so used the temperature fell to the normal within forty-eight hours, and a corresponding improvement was noted in the other symptoms. No local applications were used at any time.

The number of cases thus treated was upward of fifty, and none resulted fatally. In two cases in which improvement was at first slow, a very favorable change occurred after the dose was increased. The patients do not manifest any aversion to taking the benzoate of sodium, and Dr. Haberkorn urges his hearers most strongly to make trial of a means so simple and yet, as he believes, so effectual.

THE TREATMENT OF WHOOPING-COUGH.

WHOOPING-COUGH is ordinarily regarded as a very troublesome disease, and one whose duration is seldom materially influenced by treatment. But if we can rely upon various reports which have recently appeared in the current literature, these views must be modified very considerably. We propose to review, briefly, a few of

these different methods which have been so highly commended by their originator, leaving it to our readers to try one or more of them as they see fit.

Dr. Kohlmetz writes in the *Deutsche Medicinal-Zeitung* of June 14, 1886, that an epidemic of whooping-cough in his neighborhood has given him an opportunity to try many of the new methods, but he has found only one to give good results. He uses a solution of quinine, four parts, dilute sulphuric acid, two parts, and distilled water, two hundred parts. He fills a glass syringe (size not stated) with this solution, and injects it forcibly against the posterior wall of the pharynx, the mouth being held open and the tongue, if necessary, depressed with a spatula. Some of the solution may be spattered into the larynx, but the greater part is either swallowed or spit out, and it is difficult to account for the excellent results which the author claims to have obtained. The application is made every two hours during the first three days, and every three hours after this time, and a cure, or a very marked improvement, is obtained in from three to eight days.

In the *Centralblatt für klinische Medicin*, of June 12, 1886, Dr. J. Bachem speaks very highly of insufflations of quinine into the nostrils. He employs muriate of quinine, three parts, rubbed up with gum acacia one part, and blows about three grains of the mixture into each nostril once or twice in the twenty-four hours. In a child who had been coughing for two weeks, having from ten to twelve attacks during the day, and six to eight at night, at the end of a few days the attacks were reduced to four or five in the twenty-four hours, and a cure was obtained in three weeks. Other cases are cited in which the results were almost equally favorable. An acorn-shaped tip is attached to the insufflator, in order to insure the delivery of the powder and to prevent any loss.

We find in *El Sentido Catolico en las Ciencias Médicas*, of June 12, 1886, a reference from some other journal of the results obtained by Dr. Michael by nasal insufflations of various powders. He employed quinine, pure or mixed with benzoic acid in the proportion of one part to three—tannic acid, boracic acid, salicylic acid, iodoform, cocaine, bicarbonate of soda, and marble-dust. Of these substances good results were obtained only with quinine, benzoic acid, tannic acid, and marble-dust. The success obtained with the last-named powder would seem to imply that the curative value of insufflation is largely dependent upon mechanical causes. In eight cases a cure was obtained in three days; in six cases, in eight days, and in six other cases a marked diminution in the severity of the symptoms was observed, though the duration of the disease was not apparently influenced.

At a recent meeting of the Société Medico-Pratique of Paris (*Concours Médical*, June 12, 1886) Dr. P. Guerder stated that he had also had excellent results from nasal insufflations. He had tried benzoic acid, as used by Dr. Michael, but had been more successful with a fine powder of equal parts of boracic acid and roasted coffee. In recent cases he was able to obtain a radical cure in from eight to fifteen days, and even after the disease had become firmly established the number of attacks was reduced, after from two to six days of treatment, from fifteen or twenty to four or five in the twenty-four hours, and a like improvement was noted in the other symptoms. The insufflations were practised morning and evening.

In the fasciculus for June, 1886, of the *Rivista Clinica e Terapeutica*, appears a communication from Dr. P. Sertoli, in which inhalations of iodoform and oil of turpentine are recommended very warmly for the cure of pertussis. The writer states that he found the number of the attacks to be lessened and their severity to be diminished soon after the inhalations were begun, and the duration of the disease was also shortened, a complete cure being obtained within less than twenty days.

We have previously referred to the results obtained by Dr. Moncorvo, of Brazil, with resorcine, and very recently also to the success claimed from the employment of narceine by M. Laborde and others. These are by no means all the methods which have been brought to the notice of the profession with the endorsement of their advocates, but they will suffice to show either that pertussis is far from being the intractable disease which it has hitherto been supposed to be, or else that it is very variable in its duration and course, sometimes subsiding spontaneously whatever form of treatment be adopted.

THE VESICULAR MURMUR.

Despite the fact that auscultation of the chest has been practised for over seventy years, there are many things about it which are still obscure. This is especially the case with regard to the causation of certain chest sounds. To ascertain the cause of the normal vesicular murmur would seem at first thought to be one of the simplest problems in the study. But the greater part of the discussion has occurred upon this very question. It was formerly taught that the murmur was due to the transit of the air through the bronchial tubes; to the unfolding of the lungs upon themselves in inspiration and the exit of the air from the lobules in expiration. Then arose authorities ascribing it to the transmission of the glottic sounds by the lung-tissue. Finally, this view was displaced by that of the so-called "fluid vein," which has held its own ever since. The latter may be explained by saying that whenever a jet of fluid, either liquid or gaseous, passes from a smaller to a larger orifice, a blowing sound is produced and is due to the fluid vein, that is, the form taken by the fluid in transit. This fact accounts for both cardiac and pulmonary murmurs.

In a paper recently read by Dr. Joseph Coats, before one of the London clinical societies, some interesting data are furnished concerning the subject under consideration. Dr. Coats had the privilege of observing a patient of Dr. Newman's. The latter had removed the larynx from the patient for some malignant disease, and the man was wearing a tracheal tube, curving forward and being of very nearly the same calibre as the trachea. From the convex side of this tube a smaller one extended up into the pharynx. The patient could thus breathe with the pharyngeal tube alone open, the tracheal tube alone open, or with the tracheal tube partially closed by a stopper, through which passed a much narrower tube, so that breathing was carried on through the latter, the pharyngeal tube being closed. It must be premised that the glottis presents the conditions for the fluid vein in both divisions of the respiratory act, viz., a

passage from a smaller to a larger tube. We consequently have a double blowing sound. Similar physical conditions obtain at the remote portions of the respiratory tract, where the ultimate bronchioles suddenly open into the somewhat wider air spaces. The vesicular murmur is due to the fluid vein existing in inspiration at this point. The sound is most easily propagated in the direction in which the vein is moving. We should not, therefore, *expect* to hear the expiratory glottic sound over the trachea, but its audibility there is probably due to the false cords and base of the epiglottis. These form a sort of lip, or rim, which causes a propagation of the sound backward, that is, down the trachea. A similar illustration is seen in those cases of aortic regurgitation where the diastolic murmur is heard over the aorta itself.

In Dr. Newman's case the glottic murmurs should have disappeared, in order to be consistent with the theory advanced by Bergeon and Chauveau as a result of their experiments performed in 1877. In a horse with hepatization at the base of one lung, where bronchial breathing was heard, the trachea was incised below the glottis, and the wound held widely open. The bronchial breathing immediately disappeared over the hepatized area. It will be seen that the patient, while breathing through the tracheal tube, presented physical conditions analogous to those in the animal in the above experiment. In both the glottis was eliminated, so far as any participation in breathing was concerned. Contrary to expectation, however, Dr. Coats found that there was a loud expiratory sound heard at some distance from the patient's body, and it was propagated down the trachea and the bronchi. In the suprasternal notch and over the trachea there was a loud, blowing expiratory murmur, and a feeble inspiratory murmur. At the root of the lung, behind, the difference in intensity between expiration and inspiration was much less marked. The former was nearly as loud as the latter. The former was blowing, the latter vesicular. The equalization in intensity was probably due to inspiration, being reinforced by the normal vesicular murmur. This would indicate, says Dr. Coats, that the vesicular murmur arose in the pulmonary parenchyma. This conclusion was confirmed by auscultation of areas where we normally get a good respiratory sound. In the supra-axillary region, for instance, inspiration was distinct and prolonged, but expiration was scarcely audible. The expiratory sound, although freely conducted to those portions of the chest-wall in contact with the root of the lung, was dampened by the pulmonary parenchyma. Hence it was inaudible at the pulmonary periphery.

When the tracheal tube was plugged, and the patient breathed through the pharyngeal tube alone, the sounds were nearly natural. Inspiration was loud, with expiration nearly equal in intensity and duration. Vesicular breathing was heard all over the chest, except at the root of the lung behind, where bronchial breathing was heard as is natural.

In the third case, where the tracheal tube was partially closed by a stopper carrying a smaller tube, the condition for a fluid vein was present at the internal orifice during inspiration, and at the external during expiration. Over the trachea inspiration was much louder than expiration. The sound from the inner orifice was better carried than that from the outer. Here the result was the converse of the first case, where the tracheal tube was wide open.

Dr. Coats' conclusions are as follows: First, sounds produced at the glottis and larynx are freely conducted by the dense tissues comprising the trachea and the bronchi. They are thus audible whenever these structures are so placed as to carry sounds to the surface of the chest. They may thus be conveyed in a direction contrary to the current of air. Second, the vesicular murmur is generated in the periphery of the lungs. In all the above experiments its character remained unchanged. Even while a loud expiratory sound was heard at the base of the lungs behind, it was not communicated over them generally. The presence at the anatomical site of the glottis of any arrangement causing a fluid vein seems to have no agency in the production of the vesicular murmur.

THE UTILITY OF LIME PHOSPHATES.

The person who shows that a particular drug is of no value in therapeutics does a service to science, much more, perhaps, than by introducing a new remedy. M. E. Logeais, in the *Bulletin de Thérapeutique*, aims to prove that the phosphates, and particularly the lime salts, are useless drugs. This seems at first very much like flying in the face of a wise Providence, established pharmaceutical interests, and sound therapeutical principles. The use of the phosphates in rachitis, defective bone nutrition, and all forms of functional nerve troubles is very common, and has received the support of eminent authorities.

M. Logeais, however, quotes the experiments of Lehmann, Heiden, and Veiske, who claim to have demonstrated that the phosphates of lime added to the food are not absorbed, but are excreted in their entirety in the dejections. Dujardin-Beaumetz is quoted as saying that this salt has no action whatever, while Destage states, as a result of careful analyses of urine, that neither the phosphates of lime nor phosphoric acid is absorbed.

To this may be added the statement of Nothnagel and Rossbach: "Never, as far as we know, has a case of rickets been cured by the administration of lime." "Everywhere there is a lack of trustworthy and extensive observations," as to its utility.

All the forms of lime salts used in practice are, according to M. Logeais, precipitated and made insoluble as soon as they pass the stomach. They are, therefore, taken up, if at all, in the stomach alone, and the amount absorbed here is very small.

The practical conclusion that lime salts of all kinds are therapeutically useless, is one which deserves the attention of the many physicians who are constantly prescribing them in various conditions.

THE TREATMENT OF RHUS POISONING.

A timely article upon the treatment of rhus-poisoning appears in a recent issue of the *Journal of Cutaneous and Venereal Diseases*. The poisonous principle of *Rhus toxicodendron* (poison-oak) and of *Rhus venenata* (poison-ivy) resides in a volatile acid known as toxicodendric acid. The disease resulting is known technically as

dermatitis venenata. It is a curious fact that this poison is utterly inert with many persons, and, consequently, for the production of the dermatitis there must be some individual predisposition. So far as we can learn, dermatologists have not yet learned what makes up this curious and unfortunate predisposition. The plant is more active apparently in the spring and fall, and according to some authorities California is particularly rich in it. Even in standard works, there is a singular confusion as to the two plants which give rise to the toxicodendric acid. The poison-oak, or *Rhus toxicodendron*, is a rare plant, while the poison-ivy, or *Rhus venenata*, is comparatively common. Webster's Dictionary is incorrect on this point.

The disease which the poison produces is a dermatitis which runs a natural course of from one to six weeks, averaging perhaps two weeks. Its occasional very mild and brief course has led to the announcement of many specifics for rhus-poisoning. Specifics, however, do not in reality exist, and the most that can be done is to palliate the symptoms, and perhaps shorten the period of the inflammation.

The remedies most highly recommended by the editor of the *Journal* are the following solutions: ℞. Sodii hyposulphitis, ʒ j.; glycerinæ, ʒ ss.; aq., ad ʒ viij. M. Apply with compresses frequently renewed. When lotions cannot be continuously used the following powder is freely applied: ℞. Pulv. zinci oxid., ʒ ij.; bismuth subnitrat., ʒ j.; amyli, ʒ v. M. In later stages the following ointment may be given: ℞. Pulv. zinci oxid., amyli, āā ʒ ij.; vaseline, ʒ iv. M.

Another treatment highly recommended is the frequent application of black wash, followed at night by the following ointment: ℞. Acid. carbolic., gr. x–xx.; ung. aq. rosæ, ʒ j.; hydrarg. chlorid. mite, gr. x. M.

Both Dr. Hardaway, of St. Louis, and Dr. Van Harlingen, of Philadelphia, recommend highly a solution of sulphate of zinc, gr. ij. to O j. A mixture of fluid extract of grindelia robusta, ʒ ij. to ʒ j. of water is said to be very effective. Cloths are to be wetted with this, and then kept on the parts until they are nearly dry. Grindelia is generally believed to be the most efficient of the vegetable remedies, although Dr. Hyde, of Chicago, speaks enthusiastically of an ointment made by incorporating a decoction of the inner back of the American spice-bush (*Benzoin odoriferus*) with cold cream.

A writer in the *Philadelphia Medical Times* has recently recommended a saturated solution of oxalic acid painted on the part. No internal treatment seems to be indicated, unless it be a laxative.

It has been shown that if two persons are poisoned by the same plant, and treated in the same way, the inflammation in one case may subside rapidly, while in the other it may run a long course. This is a sufficient comment on all ordinary claims for specifics.

THE GEOGRAPHY OF THE TONGUE.

In a recent number of *The Medical World* is given a map of the tongue, which is to guide the practitioner in his explorations into the various parts of the economy of his patient. Say, for instance, that he wishes to know how it fares with the "right lung from the epiglottis to the ends of the bronchioles." Let him look into the northwest corner of the tongue (the root is to the [illegible], and the right side is to the west), and there, occupying a large territory, he will find how is the lay of this land. South of this are "the alveoli and lung tissue." In the extreme southwest, and about as small as the State of Rhode Island in comparison with the other States, is the pleura, occupying a little triangle to the right of the tip. The left side of the tongue is platted out with the respiratory passages of the left side in a corresponding manner. The alimentary canal occupies the central belt, with the exception of the tip of the tongue, which is given to the kidneys. The regions mapped out follow each other from north to south in this order: "Alimentary region from pharynx to pylorus of stomach," a very large section; then comes the duodenum, next the liver, a regular little New Jersey joining a small Delaware of pancreas, after which comes respectively the small and large intestine.

The projector of this remarkable scheme, Dr. C. C. Benton, of Baltimore, states that "this map of the tongue, with its localized seats of relationship to the various organs of the body, places before the observer at a glance the derangements, if any, which affect any of these organs." He also states that he gives us but the outline of a more elaborate system which he has developed. He recommends this to the youthful members of the profession as a stimulating scheme, which will lead them to construct for themselves a complete and reliable method of diagnosis by means of the tongue.

News of the Week.

Trouble between a Board of Managers and the Medical Board.—The daily papers have given some attention to the troubles which have arisen in connection with the Riverside Hospital at Yonkers. It seems that Dr. E. M. Hermance, after serving for six years as Visiting Physician to the Hospital, resigned. In accordance with custom and precedent, the Medical Board sent his name to the Board of Managers for appointment as Consulting Physician. The Managers accepted the resignation, but refused to make the appointment requested, because one of the Managers had made charges against him. After much delay the Medical Board succeeded in getting the charges investigated, and Dr. Hermance was fully exonerated. Still he was denied the appointment; so the whole Medical Board, consisting of Drs. Reinfelder, Upham, Swift, Benedict, Browne, Moffat, Harrington, and Seabury, resigned. Dr. Hermance has brought a suit for $20,000 damages against one of the Board of Managers. Public opinion seems to be entirely on the side of the physicians, and deservedly so. The whole amount of the affair appears to be that some of the Managers desired to show their personal feeling against one of the doctors and their authority over all of them.

The Rag Question Settled.—Acting Secretary Fairchild has issued the following instructions to customs officers in regard to the importation of old rags: "All old rags imported into the United States in vessels which have passed local quarantine at the port of importation, will be admitted to entry in the same manner as

other imported commodities, that is to say, without requiring special permits from the health officers as to their landing. The fact that the vessel has passed quarantine will be considered as sufficient evidence that her entire cargo is free from infection."

THE CHOLERA IN JAPAN.—Since the first appearance of the cholera in Japan this year, and up to June 20th, there have been 10,276 cases of the disease, 7,803 of which have been fatal. The average death-rate per 100 has been 75.93. The total number of cholera cases which occurred throughout the country, from August 23d to November 30th, last year, was 11,927, of which 7,152 proved fatal, the death-rate being 59.96.—*San Francisco Chronicle.*

A LONDON SURGEON'S FAMILY INOCULATED FOR HYDROPHOBIA.—I have seen many frivolous cases at the Rue d'Ulm. Pasteur was right to treat them seriously, since rabies on the brain may, and often does, cause death. The whole family of an eminent London surgeon went through a course of inoculations because they had been licked on the hands and faces by a dog of which ugly suspicions were entertained. They comprised a grown-up young lady, two young men and their wives, and a couple of misses in their early teens. I could not help hoping, when I saw them, that the starchy-looking stuff which Dr. Grancher injected into their flesh was of the bread-pill nature.—*Fortnightly Review.*

FANCY-BRED RABIES.—An English writer, Crawford, is authority for the statement that an American named Stephens, to test his theory that hydrophobia is fancy-bred in man, never loses a chance of getting bitten by a mad dog. He has been wounded by canine teeth forty-seven times, and a German named Fischer, who is his disciple, nineteen times. As there is certainly such a disease as simulated rabies, I should advise some society for the diffusion of useful knowledge to scatter broadcast the small volume on "Le préjugé de la Rage," by Fangère Dubourg, and what was written on this subject by such lights of science as Bouley, Brechet, Tardieu, Majendie, Bondin, Vernois, Sausen, Renault, Donnat, Baron Portal, and Dupuy.

COMPULSORY INOCULATION FOR DOGS.—A serious danger underlies the run upon the laboratory of the Rue d'Ulm. It is compulsory inoculation for dogs. Such compulsion was mooted about a year ago by the opportunist section of the Paris press, and by M. Paul Bert in the lobby of the Chamber. He wanted to give the Van Amburg of the microbes the whilom imperial seat of Villeneuve l'Etang, near St. Cloud, for an experimenting place on dogs, and eventually for a central institute for obligatory canine inoculation. This scheme was actively put forward by M. Bert in a committee-room of the Chamber in the presence of a deputy, who repeated to me what was said, and who set his face against the proposal, which he foresaw speculators would take up. There are four millions of dogs in France. The inoculation fee on each, if rated at a franc, would be four millions of francs. My friend argued he could prove from Pasteur that all the evil potency of a wild virus is latent in a tame one. Measles tamed by frequency of occurrence in old countries will decimate red Indians and South Sea Islanders, to whose organizations they are new, and if taken from them by a European will act with intense virulence. The best preventive for rabies would be in the exclusion of dogs from cities, in carefully teaching them not to eat at waysides, and in keeping tainted meat out of their way. This view prevailed over M. Bert's, because the proprietors of villas near Villeneuve l'Etang got up a movement against the château being turned into a Pasteur Institute. It may be assumed that were rabies "laid" by inoculation, and dogs still kept in unhealthy conditions and allowed to feed on offal reeking with septic organisms, that nature would show resentment in some new disease as bad or worse than the known one.—*Fortnightly Review.*

THE SUPRA-PUBIC OPERATION FOR STONE.—Sir Henry Thompson says that he does not do lithotrity when the stone weighs over two ounces. In such cases he invariably does the supra-pubic lithotomy. He has given up almost entirely the perineal operation. In the supra-pubic operation he divides the skin, supra-superficial fascia, etc., with a knife, and all the remaining tissues, including the walls of the bladder, with his finger-nails, thus avoiding hemorrhage. He does not close the opening in the bladder after removing the stone, but introduces a drainage-tube for forty-eight hours, keeping the patient on his side. Sir Henry's chief reasons for preferring the supra-pubic operation to the perineal are the almost entire absence of hemorrhage and the greater facility of removing the stone. The supra-pubic is coming pretty generally into favor here. Mr. Buckstone Brown tells me that he quite frequently does lithotrity in children.—Cor. *Amer. Practitioner.*

OVARIOTOMY AND SPECIALISTS.—Mr. Knowsley Thornton is still a warm advocate of the spray. He tells me that, now that ovariotomy is becoming so very common as to be performed by all surgeons, the specialists do not get near so many cases, and so they are paying more attention to hysterectomy and oöphorectomy.—Cor. *Amer. Practitioner.*

PONDEROUS BREASTS.—A correspondent of *The Lancet* calls up the following delicate point in casuistry: "I have a patient who suffers from great pain round the waist, and in the breasts almost constantly, due to the size of her breasts, which are unusually large. She complains that they make her life a burden to her, and constantly entreats me to amputate them. Would this be justifiable? Their weight produces a constant dragging pain from the clavicle downward, and from the back and sides forward, relieved when the weight of the breast is supported. Is there any known means of causing the breasts to contract by the application of any drug? If their weight and size could be greatly reduced it would be a boon. If any of your readers can from experience of a similar case suggest a trustworthy line of treatment I shall be most grateful."

ORGANIZATION OF INDIA-RUBBER.—M. Professor Van Lair, of Liège, announces to the Académie de Médecine the curious fact that a tube of caoutchouc placed between the two ends of a cut nerve becomes vascularized, the nerve-fibres prolong themselves into it, and finally the two ends of the nerve units, the caoutchouc disappearing.

Obituary.

ALFRED S. PURDY, A.M., M.D.,

NEW YORK.

ANOTHER of New York's oldest and most esteemed physicians has gone, in the person of Dr. Alfred S. Purdy, who died suddenly of pneumonia on the 23d inst. Dr. Purdy had been in his ordinary health up to a short time before his illness.

He was born in 1808, in this city, of which he has been a constant resident, and in which he practised his profession for fifty-five years. He fitted for Columbia College, but did not enter upon a collegiate course, determining to study surgery. He entered the office of Dr. Alexander H. Stevens, and afterward studied at the College of Physicians and Surgeons, from which he graduated in 1834. He then opened an office, and moved up town, as the city spread its limits, to his home on Madison Avenue.

In the early days of his professional life Dr. Purdy was Assistant Surgeon at Bellevue Hospital, and was also connected with the New York Dispensary. Dr. Purdy's life has been one of steady attention to his profession. He was a general practitioner, though in the past few years he has paid much attention to the study of puerperal insanity. He received the degree of A.M. from Wesleyan University.

Dr. Purdy was one of the founders of St. Paul's Methodist Episcopal Church of New York, of which he was a trustee at the time of his death. He was also a member of the Medical Society of the County of New York, of the Academy of Medicine, and of the Pathological Society.

Reviews and Notices.

STUDIES IN PATHOLOGICAL ANATOMY. By FRANCIS DELAFIELD, M.D., Professor of Pathology and Practical Medicine, College Physicians and Surgeons. Vol. II. Part 2. New York: William Wood & Co., 56 & 58 Lafayette Place. June, 1886.

THIS part contains thirty-five pages of text, upon which are described the lesions of chronic phthisis and a special lesion of lobar pneumonia. These are illustrated with twenty-seven plates.

The author is one of the most concise and comprehensive writers in the medical profession. His language is simple, his style is laconic, and at no time does he become ornate; but there is a directness of expression which points to positive opinions based upon personal investigation.

It has already been said of former fasciculi of this work, and we are ready to repeat the statement, that "the fidelity of these illustrations is beyond praise, while their execution in the different methods makes them specimens of high art." Still further, in viewing the admirable presentation of microscopical appearances, we are privileged to sit, as it were, beside the master, and almost view the specimens with his eye.

In the light of the most recent advancements in pulmonary pathology, it is interesting to notice that Dr. Delafield makes the unqualified statement that "the one essential feature of chronic phthisis is the presence of tubercular inflammation; without this there is no phthisis. Such a tubercular inflammation is not only an essential, but also a primary, part of chronic phthisis; it exists from the very commencement of the disease." "The tubercle bacilli are regularly found associated with the lesions of chronic phthisis."

The pages on lobar pneumonia constitute an appendix in which the author describes pneumonia occurring in adults, and running an *acute* course, and yet after death the air-spaces were found to contain organized new connective tissue. The special interest in the lesions exists in the fact that the author has observed it in *acute* cases. In this respect the observation is new.

All students in pathology will be highly interested in the continuation of Dr. Delafield's great work, which exhibits the care and elegance uniformly displayed by his publishers.

DISEASES OF THE SPINAL CORD. By BYROM BRAMWELL, M.D., F.R.C.P. Edinburgh. Fifty-three Colored Plates and one hundred and two fine Wood Engravings. Second Edition. Pp. 298. Wood's Library of Standard Medical Authors. New York: William Wood & Co. 1886.

THE publishers have done no small service in making Bramwell's superb work accessible to the general practitioner. Its merits are already widely known. It has been translated into German, French, and Russian, and has received the highest encomiums from critics on every side. The book is thoroughly scientific in method, and represents the most recent knowledge in spinal cord pathology. The subject is handled also with great clearness and conciseness, and is enriched with a most lavish display of colored illustrations in normal and pathological histology.

The present edition contains some changes in arrangement—a chapter on concussion of the spinal cord (which is not very good), and an appendix on pseudo-hypertrophic paralysis.

The criticisms to be made on Bramwell's book are that he has presented the pathology in a more systematic and positive way than facts will justify.

There is not very much said with regard to the art of treating spinal diseases.

The publishers have very perfectly reproduced the cuts and colored illustrations of the original work.

INSANITY AND ITS TREATMENT. Lectures on the Treatment, Medical and Legal, of Insane Patients. By G. FIELDING BLANDFORD, M.D. Oxon. Third Edition. Together with Types of Insanity, an Illustrated Guide in the Phasical Diagnosis of Mental Disease. By ALLAN MCLANE HAMILTON, M.D. Pp. 379. Wood's Library of Standard Medical Authors. New York: William Wood & Co. 1886.

DR. BLANDFORD'S book consists of twenty lectures, originally delivered at St. George's Hospital some ten years ago. These were well received, and have been regarded as furnishing a standard and trustworthy treatise. The book before us is the third edition, which the author has revised in the light of recent contributions to mental science.

We regard Dr. Blandford's treatise as one that will prove eminently helpful to the general practitioner. It is not long, and it does not go extensively into minutiæ. The specialist will read it with interest to learn the author's views, but it will not instruct him greatly.

Dr. Hamilton's "Types" have already been commented upon and commended in these columns.

VORLESUNGEN ÜBER PHARMAKOLOGIE. Ausgearbeitet für Studirende. Von DR. C. BINZ. III. Abtheilung (Schluss). Verlag von AUGUST HIRSCHWALD. Berlin, 1886. Lectures on Pharmacology for Physicians and Students. Third (and final) volume.

THE present, concluding, volume of this valuable series begins with the forty-second lecture, and covers the subjects of bismuth, silver, mercury, the antiseptics, salicylic acid, the antipyretics, fermentative acids, free acids, evacuant drugs, emollients, and counter-irritants. One cannot praise too highly these lectures of Dr. Binz. Though, strictly speaking, pharmacological, they, in reality, give much in practical therapeutics, and, as a whole, will furnish the physician a solid basis for using drugs intelligently in practice.

URINARY AND RENAL DISEASES. Illustrated by numerous Cases and Engravings. By WILLIAM ROBERTS, M.D., F.R.S., F.R.C.P., Professor of Medicine at the Victoria University; assisted by ROBERT MAGUIRE, M.D., M.R.C.P., Physician to Out-patients, St. Mary's Hospital, London. Fourth edition. Philadelphia: Lea Brothers & Co. 1885.

A PRACTICAL TREATISE ON DISEASES OF THE KIDNEYS AND URINARY DERANGEMENTS. By CHARLES H. RALFE, M.A., M.D., F.R.C.P., etc. Philadelphia: P. Blakiston, Son & Co. 1885.

THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. By SIR HENRY THOMPSON, F.R.C.S., M.B. Lond., etc. Fourth edition. Philadelphia: P. Blakiston, Son & Co. 1885.

HARN-ANALYSE FÜR PRAKTISCHE AERZTE. Von DR. S. LAACHE. Leipzig: F. C. W. Vogel. 1885.

NEW works on diseases of the genito-urinary apparatus, or at least new editions of old ones, are cropping up with such numerical vigor as to suggest one of two possibilities—either the afflictions of which they treat are on the increase, or else there is a growing demand, on the part of the profession, to know all that is knowable up to the most recent results of elaborate research pertaining to a topic that is as complicated as it is interesting. We are inclined to believe that the latter possibility represents the true state of affairs. Probably the view is gaining ground that many hitherto obscure derangements in some way depend upon morbid conditions of the genito-urinary organs. Furthermore, there exists already a widespread belief, and a very just one it is, too, that more may be learned from a systematic examination of the urine than has yet become the undisputed and common intellectual property of the medical profession.

The list of works given above by no means represents all that has found its way into the print of book-form on the subject of these disorders, even within the period of a twelvemonth. Nevertheless, it includes some of the most important publications, and we regret that it will be impossible to do more than quite briefly examine the four volumes before us. The design of Dr. Roberts' volume, of six hundred and twenty-eight pages, is to give an account of the organic diseases of the kidney, and of those diseases and disorders of which the chief characteristic is some alteration of the urine. The author has divided his work into three parts. The first is devoted to a consideration of the physical and chemical properties of the urine in health and disease, and includes two excellent chapters on urinary deposits. Part II. treats of those diseases which are chiefly characterized by some alteration in the composition of the urine, *i.e.*, diabetes, gravel, chyluria, and so forth. The organic diseases of the kidneys naturally come next, and receive in the third part that amount of painstaking attention to which their gravity and frequency so justly entitles them. Malpositions of the kidneys, cancer, tubercle, parasites, and other rare affections are treated analytically, but yet with sufficient fulness to include all the information which the practitioner is likely to desire concerning them. On the whole, it must be said that the value of this treatise as a guide-book to the physician in daily practice can hardly be overstated. That it is fully up to the level of our present knowledge is a fact reflecting great credit upon Dr. Roberts, who has a wide reputation as a busy practitioner.

Dr. Ralfe's treatise has for its object the presentation of a "clear, concise, and systematic account of urinary pathology and therapetics, based upon the latest ascertained facts, and supported by the best authorities." The work is a readable one, but, as compared with Dr. Roberts' volume, it is too evidently a careful compilation of the opinions of various authorities, rather than the result of wide personal experience, to make one wish to consult it by preference. Nevertheless the information contained in its pages is trustworthy, and there is no reason to doubt that the book will find favor with those who like a somewhat condensed style, and who prefer facts to theories.

Sir Henry Thompson's well-known monograph appears in its fourth edition, a somewhat reduced modification of the previous one. Illustrative cases are entirely removed from the present issue, since the author holds them no longer necessary to substantiate his personal views. The eminent writer's methods of treatment are familiar to the reading public, and we have merely to add that, barring some slight details, they are those universally practised both in England and our own country. Possibly, however, the American surgeon uses the conical steel sound rather more frequently than appears to be entirely prudent and advantageous. At least, Sir Henry favors the soft bougie, in many cases where we would not hesitate to employ the harder instrument.

Concerning Dr. Laache's work on urinary analysis there is nothing to say, except that it is a trustworthy guide to this important department of medical investigation. The English reader, being liberally supplied with equally good works, written in his own language, will scarcely care to provide himself with a work that does not differ materially from Tyson and similar practical manuals.

THE MEDICAL REGISTER FOR 1886. WILLIAM T. WHITE, M.D., editor. New York: Putnams.

THIS, the twenty-fourth volume of this publication, is a reproduction of its predecessors as to general appearance and scope of its contents. It contains the names of nearly seven thousand physicians, as follows: New York, 2,884; New Jersey, 824; Connecticut, 527. An increase over last year of 190.

In the New York City list 1,926 are registered; an increase of 24. Brooklyn has on its list 639; an increase of 41. Of the total number 154 are serving in the various hospitals and asylums.

The statistics in regard to the various societies and institutions are commendably accurate.

A PECULIAR ACCIDENT FOLLOWING AN OPERATION FOR HYDROCELE.—MM. Boursier and Loumeau relate the following case in the *Journal de Médecine de Bordeaux*, of June 20, 1886. A strong, healthy man, aged forty-four, of good antecedents and presenting no history, hereditary or personal, of nervous troubles, entered hospital on account of a hydrocele. There was nothing peculiar to note about the hydrocele, which occupied the right side of the scrotum, and upon which it was decided to operate by evacuation of the fluid and injection of dilute tincture of iodine. Immediately upon the injection of the first few drops the patient complained of pain in the cord and groin, and of cramps in the right forearm. The hand was seen to be slightly flexed toward the ulnar side, the little- and ring-fingers were completely flexed, while the middle-finger and index had their two terminal phalanges extended on the first, this one being flexed on the metacarpus; the thumb was flexed and drawn toward the other fingers. In a short time the same convulsive movement took place in the left hand. There were neither convulsions nor syncope, but the painful contractions persisted for some minutes and then gave way, the index and middle-finger becoming completely flexed, the hand also being flexed on the forearm. On a question being addressed to the patient it was found that he could not articulate, the muscles supplied by the hypoglossal being also contracted. The latter soon disappeared, but the contractions in the forearms and hands persisted for nearly an hour. The authors regarded the spasms as of reflex origin, but were unable to explain their localization to the muscles supplied by the median, ulnar, and hypoglossal nerves.

Reports of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

Twelfth Annual Meeting, held at Long Branch, July 21, 22, and 23, 1886.

WEDNESDAY, JULY 21ST—FIRST DAY—MORNING SESSION.

THE Association met at the Howland House, and was called to order, at 11 A.M., by the President, DR. BURT G. WILDER, of Ithaca, N. Y.

ADDRESS OF THE RETIRING PRESIDENT.

In view of the fact that he delivered a somewhat extended address upon a general subject last year, Professor Wilder confined his remarks to the brief discussion of what he believed to be a new fact, namely

THE ACCURATE COLLOCATION OF ANSIFORM AND FETAL CEREBRAL FISSURES IN THE HUMAN FŒTUS.

In three alcoholic fœtuses in the museum of Cornell University, estimated to be from three to seven months advanced, the lambdoidal suture directly overlies a short but deep fissure, which has seldom been noticed, has been hitherto misinterpreted, and may be called the *lambdoidal fissure*. A photograph and drawing of one case were submitted. The fissure is very distinct and deep, but has no ental correlative in the specimen examined. Bischoff and Huxley have regarded the fissure itself as temporary in man, though persistent in apes. Professor Wilder believed the fissure itself to persist in man also, but to lose its relation with the suture in the last two months of fœtal life. He mentioned the probability that the coronal suture is similarly related with the precentral fissure, and closed his remarks with an enumeration of several questions that arise in connection with the subject, and with suggestions as to making use of fœtal brains by careful exposure, preservation, photographing, etc.

DR. WILDER then introduced the President-elect, DR. CHARLES K. MILLS, of Philadelphia.

THE TREASURER'S REPORT

showed a balance in the treasury of $114.55.

ELECTION OF NEW MEMBERS.

The Council recommended the following candidates, who were elected by a ballot cast by the Secretary, DR. R. W. AMIDON, of New York: Drs. F. X. Dercum and James H. Lloyd, of Philadelphia; B. Sachs, J. Rudisch, and E. D. Fisher, of New York.

THE PRESIDENT'S INAUGURAL ADDRESS.

DR. MILLS then delivered his inaugural address, in which he made brief reference to the scientific work done by the members of the Association, and published in systems of medicine, encyclopædias, and medical journals. He made special reference to the organization of the Congress of American Physicians and Surgeons, and said that he was personally in favor of the Association becoming an integral part of the Congress, and that he hoped that the Association would take the steps necessary to effect such a consolidation.

Dr. Mills thought that some changes in the plan of the Congress would be advantageous; for example, that the Congress should meet every two years instead of annually; that some arrangement should be made by which the national organizations composing the Congress should in rotation receive the office of President; and that general sessions should be held mornings, and each society have its own sessions in the afternoon.

After these preliminary remarks the President proceeded to the subject proper of his paper, which consisted in a demonstration of the anatomical peculiarities of several brains, which he had collected. The first was the brain of a monomaniac; the second, that of Taylor, a criminal, the subject of delusional insanity; two others, the brains of murderers, and lastly the brain of a Chinaman and that of a feeble-minded person. His purpose was to call attention to aberrations in development, and in general terms they were such as allied them to the simian brain. The peculiarities related to bulk, simplicity of convolutions and fissures, atypical asymmetry, confluence of fissures, etc., and they indicated a low order of human beings. In only the specimen presented had he ever observed complete confluence of the fissures of Sylvius and Rolando.

The paper was discussed by Drs. B. G. Wilder, of Ithaca; L. C. Gray, of Brooklyn; F. X. Dercum, of Philadelphia; Joseph Jastrow, of Johns Hopkins (by invitation); W. R. Birdsall and B. Sachs, of New York, and the discussion was closed by Dr. Mills.

The Association then adjourned to meet at 3 P. M.

AFTERNOON SESSION.

The Association was called to order by THE PRESIDENT.

DR. L. C. GRAY, of Brooklyn, read a paper in which he gave the history of

A CASE OF LESION OF BOTH TEMPORAL LOBES, PRODUCING GENERAL LOSS OF MEMORY, ALMOST WORD DEAFNESS AND WITHOUT DEAFNESS.

The patient was a man forty-three years of age, single, and an American, who gave an indirect history of syphilis. The mental faculties, other than loss of memory, were intact. He had convulsions, remained comatose thirty-six hours, and then died. The autopsy showed a normal skull and normal dura mater, lepto-meningitis of both the right and the left temporal convolutions, extending around the fissure of Sylvius, involving the gyrus marginalis and the bases of the ascending frontal and parietal convolutions. Besides, there were minute hemorrhages and chronic endarteritis.

The case was in accord with one reported in 1884, by C. Westphal, the details of which Dr. Gray gave.

The paper was discussed by Dr. Philip Zenner, of Cincinnati.

DR. V. P. GIBNEY, of New York, then read the history of

A CASE OF PSEUDO-HYPERTROPHIC PARALYSIS,

from which microscopical sections had been prepared by DR. R. W. AMIDON, of New York, who demonstrated the changes that had taken place. This consisted in a marked paucity of motor-cells in the anterior horns, particularly in the lumbar and dorsal regions, and those which remained had only few processes and took the staining agents poorly.

Dr. Gibney raised the question as to whether there was any cord lesion distinctive of this affection, or was it simply an interstitial myelitis; also, whether the later stages of this disease were distinguishable by clinical features from each other or from progressive muscular atrophy.

The communication gave rise to discussion participated in by Drs. G. W. Jacoby and B. Sachs, of New York; Philip Zenner, of Cincinnati; L. C. Gray, of Brooklyn; F. X. Dercum, the President, and J. H. Lloyd, of Philadelphia; R. W. Amidon and G. M. Hammond, of New York; the general tenor of which was to doubt the existence of a spinal lesion, and that the two diseases were closely allied, if not identical.

DR. SARAH J. MCNUTT, of New York, then read a paper in which she reported

THE CASE OF AN INFANT WITH MULTIPLE TUMORS OF THE CEREBRUM, PROBABLY OF SPECIFIC ORIGIN.

The autopsy was made by Dr. T. E. Satterthwaite, and the microscopical examination was made by Dr. W. H. Porter and Dr. W. A. Shufeld, of New York.

Dr. G. Belton Massey, of Philadelphia, then read a paper

ON THE CAUSE OF ELECTROTONUS AND OF THE NORMAL FORMULA OF POLAR REACTIONS.

After referring to the greater action of the cathode in both electrotonus and electro-contraction, the reader drew preliminary attention to the laws of current distribution within large conductors, and exhibited drawings of the potential planes and lines of flow modelled from the results of actual measurements within tubs of salt-water by Professor W. G. Adams, of England. These measurements showed that the potential of either sign gradually lessened from the electrode toward the middle of the body, where it was zero. A nerve placed anywhere between an electrode and the middle of the body would, therefore, be bathed in the polarity of that electrode, with no other polarity in the immediate neighborhood, as held by Erb, De Watteville, and others. This theory of Erb—first advanced by Helmholtz—of a *peripolar* region of opposite polarity in the immediate neighborhood of each pole, is consequently opposed to the proven laws of physics.

In explaining the admitted fact of the greater action of the cathode some other theory must be adopted. The reader thought that the proper explanation lay in the correction of a misconception in physics: the direction of the current is probably the reverse of that now held, being from the cathode to the anode. Such an assumption would require a radical change of ideas as to which was the real positive pole, or pole of raised level, but would not interfere with the laws of electricity in any way. Its adoption would make both electrotonus and electro-contractility rational and comprehensible, for catelectrotonus would then be due to a raised potential in a nerve, and anelectrotonus to a depressed potential. Cathodic closure produces greatest contraction because it is the application of electric energy to the nerve, and anodic opening comes next because it is a backward rush of normal potential. Many facts in physics make it probable that this direction of currents is the true one, while it effectually disposes of the contradictory terms involved in still calling the pole most positive in its action on the body the "negative pole."

The paper gave rise to discussion, participated in by several members, after which the Association adjourned to meet at 10.30 A.M., Thursday.

Thursday, July 22d—Second Day—Morning Session.

The Association was called to order by The President, and the first paper was

THE REPORT OF THE COMMITTEE ON DOSAGE OF ELECTRICITY

appointed at the last annual meeting, and consisting of Drs. George W. Jacoby, W. R. Birdsall, and R. W. Amidon, of New York.

The Committee reported that special rules applicable to all cases for the use of the current strength, or for the length of time to be devoted to each application of electricity, did not exist, and, in the nature of things, could not be formulated; that all conclusions arrived at by any special investigator or series of investigators—no matter with what mathematical accuracy these conclusions be expressed—could only be arrived at empirically, and were dependent upon private experience and personal views. Therapeutic experience is too weak a foundation upon which to build an edifice of such magnitude as electrical dosage.

The Committee, however, recommended the employment of all possible accuracy, in concordance with present scientific knowledge, in the application of electricity. It advocated the use of the measures adopted by the International Electrical Congress of 1881; also the use of an accurate galvanometer divided according to the system. Furthermore, the Committee recommended the adopton of electrodes of certain diameters, with their square distinctly marked upon them in square centimetres (Erb's normal electrodes).

It was also recommended that a system of expressing the current used, in accordance with these facts, be adopted, and that a fraction be always used of which the numerator represented the number of milliampères employed, and the denominator the number of square centimetres contained in the electrodes.

The report was discussed by Drs. L. C. Gray, of Brooklyn; J. H. Lloyd, of Philadelphia; L. Weber, of New York; G. Belton Massey, of Philadelphia, and the discussion was closed by Dr. Jacoby.

Dr. R. W. Amidon, of New York, Secretary, presented a photograph of a

MICROCEPHALIC GIRL,

fifteen years of age, who had three sisters in the same condition, and which had been received from Professor A. Forel, of Zurich, Associate Member; the father and mother were normal.

The next paper was by Dr. Burt G. Wilder, of Ithaca, and entitled

NOTES ON THE BRAIN.

FIRST—ADDITIONAL CASE OF INDEPENDENCE OF THE PAROCCIPITAL FISSURE.

In his recent paper on the paroccipital fissure Professor Wilder stated that, among forty-three reliable specimens and figures accessible to him, the paroccipital is continuous with the parietal in twenty-one, and independent in twenty-two. The brain of a negro child at birth, lately prepared by him, had the two fissures wholly independent on the right, and barely united by a shallow junction on the left.

SECOND—AN ENTAL CORRELATIVE OF THE OCCIPITAL FISSURE IN THE EARLY FŒTUS.

In a fœtus, estimated to be about six or seven months old, as shown in an accompanying photograph and figure, opposite the occipital fissure there was a distinct ental ridge, so that the entire thickness of the wall was there folded. A similar ridge is figured by Tiedemann, but not named or described. Without further observations it cannot be determined whether it disappears in the adult, or persists as the more or less distinct elevation known as the *bulbus cornu posterioris* or *eminentia splenialis*. Even if transitory, it adds another to the list of "total fissures," including the calcarine, hippocampal, collateral, and sylvian.

THIRD—THE FŒTAL EXTENSION OF THE PROPLEXUS TO THE END OF THE POSTCORNU.

This is the case in a fœtus estimated to be seven months old. The postcornual extension is apparently in process of atrophy. There were indications of a like extension into the precornu. These extensions might be expected in view of the great volume of the plexus at a still earlier stage.

FOURTH—POINTS ILLUSTRATED BY THE TRANSECTION OF A FŒTAL BRAIN.

Six points of morphological interest were noted, most of them indicating that the thalami increase in width as development proceeds, so that in the adult human brain they form, or seem to form, part of the floor of the procœles or lateral ventricles, which is not the case in other mammals, excepting, perhaps, the primates.

The communication was discussed by Drs. Gray, Mills, and Wilder.

The President announced the reception of

THE BRAIN OF A NEW-BORN NEGRO CHILD

from Dr. Formad, of Philadelphia.

Dr. L. Weber, of New York, then read a paper

ON THE PSYCHO-NEUROTIC MELODY WHICH ACCOMPANY AND OFTEN MASK LATENT PULMONARY DISEASE.

It was a daily observation that there was a special condition of the mind associated with pulmonary tuberculosis. Frequently it consisted in a peculiar, cheerful hopeful condition, which seemed to be strongly out of harmony with the unmistakable signs of the advancing fatal disease by which it was accompanied.

But there was also a state of marked mental depression which had been noticed in intimate association with the disease.

The peculiar hopefulness was most frequently seen in the acute form of phthisis, and it was often so irrational and persistent as to amount to an insane delusion. In the last stage of such cases the emotional exaltation was often extreme, and actual delirium not unfrequent. The opposite mental condition was met with in chronic phthisis, more especially in that form which had been called latent. All through the course of the disease there was depression and distrustfulness, although the symptoms were neither so depressing nor so obvious as in the acute forms. The mental symptoms sometimes preceded the physical signs, and were such as languor and depression mingled with waywardness, rather characteristic of the initial stage, and usually accompanied by general functional debility. In many cases the physical signs of pulmonary phthisis were apt to be overlooked; in others they escaped observation for years, although repeated and careful examination may have been made by careful observers.

Again, when the mind was much affected the symptomatic cough and expectoration and dyspnœa were often absent; and that was the case sometimes when physical exploration revealed the existence of quite large excavations present in advanced phthisis. Occasionally fits of considerable excitability and excitement might vary the picture. There was a general disinclination to enter into any kind of amusement or continuous work, and even if it was overcome, there was no interest manifested in the employment. This condition might be called a mixture of subacute mania and dementia. If there was any single tendency that characterized the mental state in these cases it was *to be suspicious*.

Dr. Weber related illustrative cases occurring in women. The treatment should be very largely hygienic and dietetic.

The paper was discussed by Drs. L. C. Gray, of Brooklyn, R. L. Parsons, of Sing Sing, and J. Van Bibber, of Baltimore, who mentioned cases illustrating the phenomena described by the author of the paper, and the discussion was closed by Dr. Weber.

Dr. Philip Zenner, of Cincinnati, O., presented a patient who was the subject of

AUCTIONEER'S CRAMP.

It belonged to the group of cases which were termed professional neuroses, of which "writer's cramp" was the most common and the best type. The patient had worked in his occupation to an extreme degree, and all at once he discovered that something was the matter with his mouth as he cried a sale. The muscle chiefly affected was the orbicularis oris, and particularly the left part. The man was forty-five years of age, with good family history, and had always been in excellent health. There was no evidence of further disease of the nervous system. As he said, "Five, five, five," etc., as in crying a sale, for example, there was considerable muscular spasm about the mouth, accompanied by a sense of exhaustion.

Dr. Zenner said that the diagnosis of professional neurosis was based upon the fact of excessive use of affected muscles in the patient's occupation, and the fact of the spasm being excited by the direct exercise of those muscles, which were the basis of all professional neuroses. It was possible that there was a neuritis present, as had been found in various cases of writer's cramp, but the evidence of its presence in this case was not strong.

The case gave rise to considerable discussion, participated in by the President; Dr. Gray, of Brooklyn; Dr. Weber, of New York, and the discussion was closed by Dr. Zenner. The question of diagnosis was the chief point at issue.

The Secretary read a communication received from

acknowledging his high appreciation of the honor conferred upon him by being elected to Corresponding Membership at the last annual meeting. [It will be remembered that Professor Gudden lost his life at the time the mad King Ludwig committed suicide.]

The Association then adjourned, to meet at 3 P.M.

Dr. Burt G. Wilder, of Ithaca, exhibited

SEVEN MONTHS AGO.

The frog was in excellent health, could change his position, balance himself, execute the retrograde movement, wink with one eye, would not open his mouth voluntarily, but did not know any better than to attempt to do two things at the same time, the reverse of each other; for example, try to swallow one end of the minnow, and with his foot endeavor to scratch the other end of the fish out of his mouth.

Remarks were made by Drs. Gray, of Brooklyn; Sachs, of New York; Jastrow, of Baltimore, and Zenner, of Cincinnati.

Dr. C. L. Dana, of New York, then read a paper on

in which he reported two original cases. The object of his paper was to report these somewhat unique cases, presenting the symptoms of tabes dorsalis; next to show that arsenical paralysis, like those from diphtheritic poison and alcohol, presented two types: 1, What might be called the mixed or ordinary form; 2, the ataxic form; and finally, to show that the ordinary teachings that arsenical paralysis was due to a diffuse myelitis was incorrect, and that these paralyses were really the result of multiple neuritis. His conclusions were:

First.—That a disease resembling locomotor ataxia may be caused by arsenic given indiscriminately, absorbed from wall-papers, or taken in single large doses.

Second.—That arsenical paralysis of this type and arsenical paralysis of other types are not due to a diffuse myelitis, as has been taught, but to multiple neuritis.

Third.—The arsenical paralysis, like those from diphtheria, alcohol, and probably other infectious diseases and poisons, are of two types: (1) The ordinary mixed motor and sensory paralysis, the motor troubles and atrophy being marked; and (2) the pseudo-tabetic form, in which there is no pronounced motor paralysis, but marked sensory troubles, and especially ataxia.

The paper was discussed by the President, and Dr. Sinkler, of Philadelphia; Dr. Jacoby, of New York, and Dr. Sachs, of New York, and the discussion was closed by Dr. Dana.

The general result of the discussion seemed to be that various parts of the body might be involved by these poisons, and that it could not be safely accepted that the lesions produced were exclusively either a myelitis or a neuritis, but with the evidence rather in favor of neuritis as against myelitis.

Dr. Wharton Sinkler, of Philadelphia, then read a paper on

THE TREATMENT OF PAINLESS FACIAL SPASM.

The treatment of tic non-douloureux was unsatisfactory, and, according to Erb, one of the most thankless

problems of medical practice. All authorities agreed that therapeutic measures were of but little use in the treatment of this annoying affection. Various drugs had been spoken of favorably in its treatment, but he had not been able to find reports showing that any cases had been cured for a length of time by any single remedy. Surgical measures had, therefore, become necessary to afford relief. Dr. Sinkler then mentioned the various operations which had been resorted to, such as section and resection of nerves, etc. (In the case which he reported resection of the infraorbital nerve did not produce any permanent relief.)

The possibility of stretching the facial nerve naturally suggested itself, after other nerves had been stretched with good results, and the operation was first performed by Baum for the relief of facial spasm in 1878. The patient was cured for eight or nine months, and then had a slight relapse, but after two years she was comparatively free from the disorder. There have been since Baum's operation twenty others, the last being the case which Dr. Sinkler reported, and in which the patient, a woman forty-nine years of age, came under observation first in the summer of 1883. She received a great variety of treatment without much relief, until the facial nerve was stretched by his colleague, Dr. W. W. Keen, in April, 1886.

Dr. Sinkler then quoted from Dr. Keen's table, which showed that there had been 21 cases of tic convulsif in which the facial nerve has been stretched with the following results: complete relief in 5. In Dr. Sinkler's case there had been no return except the trifling twitching of the lower fibres of the orbicularis. In 14 cases complete relief, in 3 lasted only one week, and after that time in 1 of them the improvement lasted for two years, and in the other there was no improvement.

In 5 cases complete relief lasted from three weeks to four months; of these 4 continued improved, and 1 was finally not any better than before the operation.

In 6 cases there was absolute relief from four months to one year; of these, improvement continued in 3, and there was no improvement in 3.

Of the whole number (21) there were but 6 in which it was reported that there were no relapses and the condition as bad as before the operation. There was but 1 case in which there was not complete relief for a longer or shorter period. It was true that none of these cases were under observation long enough to make a thorough test of the value of the operation, but no one means had given relief in so large a proportion of cases.

Dr. Sinkler was inclined to believe that in his case the disease was of peripheral origin, from the fact that she had two attacks of chorea in early life, and also the influence which the menstrual periods exerted upon the facial spasm.

The paper was discussed by the President, Dr. Massey, of Philadelphia, and Dr. Dana, of New York, who regarded statistics as extremely fallacious.

Dr. E. D. Fisher, of New York, then read his inaugural thesis, which was entitled

REMARKS ON EPILEPSY.

The object of the paper was to show the central character of epilepsy, and to place it among organic diseases, rather than functional disorders—a chronic disease of the cortex, with progressive decline toward insanity, belonging to the class of cases called general paresis.

Dr. B. Sachs, of New York, then read his inaugural thesis, entitled

INTRACEREBRAL HEMORRHAGE IN THE YOUNG.

After referring to the increased attention neurologists were paying to the cerebral accidents of children, the writer recorded his conviction that intracerebral hemorrhage was more frequent than it was generally supposed to be, and that many cases of this sort were commonly classified under the head of meningeal hemorrhage.

Dr. Sachs then reported two cases of intracerebral hemorrhage, one in a boy two and a half years old, and the other in a young man of nineteen years. The history of the first case was given in full, in order to place the diagnosis on a firm basis. The child had typical right hemiplegia with aphasia, without coma or convulsions, at the time of onset. The onset was slow, aphasia setting in first, paralysis of the arm and leg some hours later. The recovery was typical of that which takes place in many cases of adult hemiplegia from apoplexy. The reasons were given why the writer held that in this case the apoplectic attack was due to hemorrhage rather than to embolism or thrombosis. As regards the differential diagnosis between meningeal and intracerebral hemorrhage the lack of convulsions seemed to be of unusual significance. In meningeal hemorrhage convulsions are invariably present, so their absence might argue, other things being equal, in favor of intracerebral hemorrhage. The second case was that of a young man who had had two apoplectic attacks exactly one year apart. The histories of these attacks were very similar to the one given in the first case. Using these cases as a basis, the author of the paper entered upon a discussion of the changes in the walls of cerebral arteries, permitting an effusion of blood into the brain substance. Autopsies on this condition in the young are very scarce, but there was good reason for supposing (reference was made to some recently reported cases of Dr. Osler) that miliary aneurisms occurred in young children, and that fatty degeneration of the cerebral arteries (permitting transudation of blood through the vessel-walls, Recklinghausen) was a not infrequent condition.

The paper was discussed by the President, Dr. Lloyd, of Philadelphia; Dr. Zenner, of Cincinnati; Dr. S. J. McNutt, and Dr. Amidon, of New York, and the discussion was closed by Dr. Sachs.

The Association then adjourned, to meet on Friday morning.

Friday, July 23d—Third Day.

The Association was called to order by The President.

Dr. Burt G. Wilder, of Ithaca, presented the first scientific subject, which consisted in

AN EXHIBITION OF THE MEDISECTED ALINJECTED HEAD OF A MURDERER.

The features of the brain, which was thus hardened and exposed *in situ*, are to be discussed at a future meeting in comparison with another murderer's brain; the specimen was shown in illustration of the value of the method of *continuous arterial alinjection*, which has been applied to other heads, to brains, and to entire bodies (children, a chimpanzee, etc.) in the anatomical laboratory of Cornell University. The main features of the method are: (*a*) the reception of the head within twenty-four hours; (*b*) preliminary washing out of the vessels with chloral (to which, perhaps, weak alcohol might be preferable); (*c*) continuous alinjection for a week; (*d*) continuity secured by a pressure of eighty millimetres of mercury, which was reduced to forty millimetres when the flow became somewhat free; (*e*) gradual increase of the alcohol from sixty-five to ninety-four per cent; (*f*) maintenance of a low temperate (8° to 11° C.); (*g*) accurate division of the head with a fine saw acting in a mitre-box; (*h*) the small cost. The injected alcohol represented 41.5 litres of ninety-five per cent., but about two-thirds was regained; so at $3 per gallon it would cost $11, and at 75 cents (free of tax) only $3.

Dr. James H. Lloyd, of Philadelphia, then read his inaugural thesis entitled

MORAL INSANITY: A PLEA FOR A MORE EXACT CEREBRAL PATHOLOGY.

It was substantially an argument against the use of the term or the existence *per se* of the condition now called *moral insanity*. He would not object to classification and believed that differences must be recognized, but

regarded "moral insanity," so-called, as a disease of the unit, the brain. Moral insanity proceeds upon an abstraction, just such as Locke warns his readers to avoid. It teaches that there is a moral "faculty" in the sense of a distinct agent, which has its own powers, and its own diseases, and which may remain undeveloped in a "mind" otherwise healthy, or may become diseased without at all affecting the health of the other "faculties." It is nearer the truth to say that the whole brain-act of an insane man is wrong—judgment, emotion, memory, and will. To say, for instance, that a man's intellect is sound, and his will diseased, is a sophism, which has more sound than reason.

The discussion was participated in by PROFESSOR JASTROW, of Johns Hopkins, the PRESIDENT, and DR. GRAY, of Brooklyn, all of whom thought it difficult to get rid of the term, and, furthermore, that there were cases to which no other term could be applied that would so well express the peculiar mental condition indicated.

DR. RALPH L. PARSONS, of Sing Sing, felt certain of the existence of moral insanity, but, at the same time, believed firmly that in *all* forms of insanity, with which he was acquainted, all the mental faculties were more or less involved.

The discussion was closed by Dr. Lloyd.

The inaugural thesis of DR. J. RUDISCH, of New York, was read by DR. GEORGE W. [illegible], of New York, and consisted in the description of

A NEW PORTABLE GALVANIC BATTERY,

accompanied by demonstrations of the efficiency of the apparatus. The essential practical features were, that it was essentially a dry battery, if desired; that the carbon and zinc were separated by a stout piece of asbestos paper, which increased the internal resistance of the cell, facilitated the escape of the hydrogen bubbles, and enabled the battery to be used without a trough. The exciting fluid was a solution of sal ammoniac (1 to 4).

The inaugural thesis of F. X. DERCUM, of Philadelphia, was read by title: "Facts and Deductions bearing on the Action of the Nervous System."

AMENDMENTS TO THE BY-LAWS AND CONSTITUTION.

By DR. R. W. AMIDON, of New York: "The officers shall enter upon their duties immediately after the adjournment of the annual meeting at which they are elected."

By DR. C. K. MILLS, of Philadelphia: "Two Vice-Presidents instead of one Vice-President."

By DR. G. W. JACOBY, of New York: "They (officers) shall be nominated by the Association on the *second* day of the annual meeting" (instead of the first day).

"There shall be two sorts of members, namely active members—not exceeding at any one time one hundred in number" (instead of fifty as at present).

RESOLUTIONS.

DR. L. C. GRAY, of Brooklyn, introduced a resolution endorsing the proposition of the proposed "Congress of American Physicians and Surgeons," and moved that a committee of conference of five be appointed by the president. The resolution and the motion were adopted.

THE PRESIDENT appointed Drs. L. C. Gray, of Brooklyn; J. Van Bibber, of Baltimore; W. Sinkler, of Philadelphia; E. C. Seguin, of New York, and Philip Zenner, of Cincinnati.

OFFICERS FOR THE ENSUING YEAR.

President—L. C. Gray, M.D., of Brooklyn.
Vice-President—John Van Bibber, M.D., of Baltimore.
Secretary and Treasurer—G. M. Hammond, M.D., of New York.
Councillors—B. Sachs, M.D., of New York, and Wharton Sinkler, M.D., of Philadelphia.

The Association adjourned to meet in June, 1887, on the date and at the place to be designated by the Council.

[illegible] THE [illegible]

Burt G. Wilder, of Ithaca; L. C. Gray, of Brooklyn; Philip Zenner, of Cincinnati; John Van Bibber, of Baltimore; R. L. Parsons, of Sing Sing; C. K. Mills, W. Sinkler, G. B. Massey, J. H. Lloyd, and F. X. Dercum, of Philadelphia; R. W. Amidon, G. M. Hammond, V. P. Gibney, G. W. Jacoby, S. J. McNutt, C. L. Dana, L. Weber, W. R. Birdsall, E. D. Fisher, and B. Sachs, of New York.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, March 9, 1886.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

DR. H. MARION SIMS presented, in behalf of a candidate, a specimen of

[illegible] TISSUE OF THE [illegible]

DR. T. MITCHELL PRUDDEN presented specimens which illustrated

TRAUMATIC PERINEPHRITIC ABSCESS, FOLLOWED BY [illegible] NEPHRITIS: NO CONSECUTIVE ABSCESSES OF KIDNEY, SPLEEN, AND LUNG.

A man about thirty years of age was kicked in the left side by a horse three years ago. A perinephritic abscess shortly afterward developed and was opened. A permanent fistula remained, which at times was uncared for, and continued to discharge more or less pus. Patient developed cough with purulent expectoration, and fancied that, after the wound was washed with carbolic acid, on coughing he could taste the latter. He was in hospital suffering from an uncontrollable diarrhœa, had considerable amount of pus in the urine, and finally died from exhaustion.

Autopsy.—Brain not examined. Omentum besprinkled with small gray tubercles. Heart normal. Lungs: Right emphysematous, congested, and œdematous, with few scattered gray tubercles. Left pleural cavity contained about one hundred cubic centimetres yellowish turbid serum and a considerable quantity of fresh fibrin; upper lobe contained a few scattered tubercles; the lower lobe was irregularly solidified, white and smooth in the denser areas. Microscopical examination of this lobe showed interstitial and intra-alveolar pneumonia, with commencing organization of the contents of the air-vesicles. At the base of the left lung was an abscess about three centimetres in diameter, communicating with a small subcutaneous abscess between the eleventh and twelfth ribs, and also through the diaphragm, with an abdominal abscess behind the spleen in the abdominal cavity. Right kidney large; capsule adherent; cortex thick, mottled gray and red, translucent; markings obscure; microscopical—chronic diffuse nephritis; waxy. Ureter slightly dilated. Left kidney: Capsule very thick and surrounded by a dense mass of connective tissue, binding it firmly to adjacent parts. A fistulous opening from the back led directly into a series of ramifying cavities which occupied about three-fourths of the entire organ. These cavities were partly filled with a purulent detritus, their sides were rough, and their walls composed of yellowish, friable, cheesy material. Between these cavities were irregular bands of translucent connective tissue. Microscopically, the walls of the cavities are seen to be composed of tubercle tissue, cheesy material, and connective tissue in a condition of suppurative inflammation. Very little kidney tissue remains. At the upper end of the organ these cavities were in direct communication with a post-peritoneal abscess cavity, which involved about one-fifth of the moderately

enlarged waxy spleen, and communicated, as above described, with the abscess of the lung. Ureter not dilated, and apparently normal. The liver was large and waxy. The villi of the small intestine were in a moderate degree waxy. The mesenteric glands, as well as the lymph glands about the left kidney, were very large and red. The mucous membrane of the bladder was thickened, and covered with a very thick, tenacious layer of mucopus.

Dr. Prudden remarked that the absence of any old cheesy or tubercular lesion than that in the kidney, and the fact that this had been exposed through the fistula to the external world for three years, would suggest the probability that this was primarily a case of local infection through the kidney, becoming general later, as evidenced by the fresh tubercles elsewhere.

Dr. Eugene Hodenpyl presented specimens from a case of

LEUCÆMIA

with the following history: The patient states that up to eight months ago he was in perfect health. At that time he received an injury to the left hand, which was followed by inflammation and abscess of the forearm, which, being opened, resulted in an indolent ulcer. Six months ago, without known cause, an abscess formed in the left thigh. It also resulted in an indolent ulcer. Three months ago patient noticed for the first time a change in the color of his skin, and that he was gradually losing his strength. His appetite began to fail, and he became troubled with frequent attacks of diarrhœa. Two months ago he noticed a swelling in the epigastrium, which was somewhat tender. At the same time anasarca of the feet and ankles developed, which gradually extended upward. For the past six weeks he has been greatly troubled with a cough and dyspnœa, which made it difficult for him to obtain sleep. On account of the dyspnœa he was able to take food only in small quantities. Patient says he has had no hemorrhages.

On admission patient was fairly well nourished. Skin of a peculiar dirty yellowish-white color. The mucous membranes are almost bloodless. The superficial glands throughout the body are enlarged and very hard. The tonsils were hypertrophied, and on the surface of the left one were three small cicatrices, and also one on the uvula. Lungs showed evidences of a chronic bronchitis. Area of heart-dulness increased. A systolic murmur at the apex and a loud anæmic bruit were heard with the first sound at the base. Liver enlarged and painful on pressure. Area of splenic dulness increased and pressure over it caused pain. No fluid was detected in the abdominal cavity. Blood examined two days before death was of acid reaction, and contained a very large increase in the number of white blood-cells. Pulse, 120, and feeble; respiration, 23; temperature, 101.6°, and while in the hospital it varied between 99° and 102°. The patient complained mostly of the dyspnœa. During the night of May 23d there was quite violent delirium, but in the morning patient was rational but very much exhausted, and in the afternoon of May 24th he died.

Autopsy, sixteen hours after death. Rigor mortis not at all marked. Body well nourished. Skin was of a peculiar dirty white color. Brain not examined. Small amount of clear serum in both pleural cavities, and there was fresh fibrin on both pulmonary pleuræ. Both lungs presented the lesions of chronic bronchitis and the pneumonia of heart disease. The pericardial sack contained eight ounces of clear serum. Heart was hypertrophied and dilated, and the cardiac muscle was paler than was normal; its cavities were distended by a large amount of decolorized blood-clots; the mitral valves were thickened. Liver enlarged and fatty. Spleen was enlarged to about three times its normal size. Its surface showed several points of an old perisplenitis. It was soft, and its cut surface, besides showing numerous spots of lighter color than the surrounding spleen tissue, also presented several large, somewhat irregular, masses of a light-red color. Kidneys were enlarged and very pale; on the surfaces were small hemorrhagic spots, and numerous masses of dense, almost white, tissue were scattered throughout the parenchyma. The lymphatic nodes throughout the body were enlarged and very hard. Cross-section through the sternum showed the marrow to be of a red color, and an apparent increase of the medullary space.

The specimen had been examined by Dr. T. Mitchell Prudden, who had made the following report: "Microscopical examination of the spleen shows a considerable degree of acute hyperplasia, chiefly involving the pulp. The kidney shows a moderate amount of chronic diffuse nephritis with circumscribed nodules, formed by an infiltration of the interstitial tissue with leucocytes. In some places the infiltration is moderate in amount, while in others it is so extensive as to have led to the nearly complete destruction of the enclosed tubules."

MULTIPLE STRICTURES OF THE ŒSOPHAGUS—GASTROSTOMY.

Dr. A. Jacobi presented specimens removed from the body of a man, forty-three years of age, a native of Ireland, and a laborer, who, in August, 1885, drank some spirits of ammonia by mistake. He vomited quickly, and for three days had great pain. Since then he has had gradually increasing difficulty of swallowing, especially solids, the dysphagia being more marked at some times than at others. A short time ago he was sounded with bougies, and he says that a small one was passed. For the past four months he has had pain in his right side about the region of the seventh rib, which has been especially severe when he has coughed, or has used his diaphragm forcibly. The patient has lost much flesh. He denies syphilis, gonorrhœa, and rheumatism, but has a well-marked alcohol habit.

On the day after admission to the hospital, May 5, 1886, numerous efforts were made to pass bougies, but they failed. The smallest bougie passed two or three strictures, but became fixed at another considerably nearer the stomach. On May 8th efforts were made to pass still smaller bougies, but they failed, and on May 10th Dr. Jacobi performed gastrostomy. The abdomen was opened with a rather long incision, but it was found necessary to prolong it downward on account of the relatively large size of the liver, until it was finally about three and a half inches in length. The stomach was not opened, but was stitched to the abdominal wall with a large number of stitches to facilitate adhesive inflammation. The proposition was to open the stomach when it had become completely adherent to the abdominal walls, and then treat the strictures of the œsophagus from below.

The shock of the operation was very profound, and lasted three hours. The patient died of exhaustion, May 13th, at 11.35 P.M.

The autopsy was made by Dr. T. Mitchell Prudden, who makes the following report:

Body much emaciated; slight rigor mortis. An incision in left abdominal wall, parallel with free border of ribs, about ten centimetres long, closed, except at its lower end, by sutures; no fluid peritoneal exudation; surface of small intestine presents scattered patches of dull lustre, and the same, with a very little fibrinous exudation on surface of stomach and abdominal parietes, near the incision; abdominal wall firmly and completely adherent to surface of stomach around opening; omentum dull lustre, with greatly congested blood-vessels; mesenteric glands moderately enlarged; blood vessels congested. Heart: About fifty cubic centimetres; slightly turbid, yellowish fluid in pericardial sac; moderate chronic thickening of the aortic and mitral valves, with general slight opacity of the endocardium; a small fibrinous clot, about two millimetres in diameter, adherent to one of the aortic cusps. Lungs: Pleural cavities empty; both lungs show the lesions of emphysema and chronic

bronchitis; both lower lobes contain numerous scattered areas of broncho-pneumonia, and both present irregular patches of fresh fibrinous exudation on pleural surfaces. Spleen: Small; trabeculæ unusually distinct. Kidneys: Small; capsule thick and adherent; cortex thin; markings obscure; cut surface slightly rough. Liver: Small; appears normal. Intestines: Considerable congestion of mucous membrane; otherwise normal. Stomach: Shows much tenacious mucus; irregular pigmentation of the mucous membrane; no evidence of inflammatory reaction about the opening internally. Tongue and epiglottis appear normal. Œsophagus has a normal diameter for 10 ctm. from the tip of the epiglottis. It then narrows for 1.5 ctm. to a circumference of 2.2 ctm., then gradually widens. Just below this first constriction are two small openings leading into a submucous pocket of about one centimetre in area. Below this point the whole œsophageal mucous membrane is irregularly thickened, and presents a very uneven surface.

At 20 ctm. from the tip of epiglottis is another dense constriction about one centimetre long, having a circumference of about 1.2 centimetre. The tube now again widens to a circumference of about three centimetres, the mucous membrane being beset with fibrous cords, patches, and longitudinal thickenings.

At about twenty five centimetres from the tip of the epiglottis are two openings leading sideways into a five centimetres long, irregular-walled, suppurating cavity, which harbors a couple of fragments of egg-shell.

At thirty centimetres below the tip of the epiglottis the œsophagus rather suddenly contracts, leaving an opening of about three millimetres in diameter. This constriction is about two millimetres long, and below it the œsophagus widens out into the stomach.

The above-mentioned submucous suppurating cavity passes behind the last constriction and opens into the stomach below it.

The anatomical diagnosis is, accordingly, chronic and excessive œsophageal stricture, gastrotomy, commencing acute peritonitis, chronic endocarditis, chronic bronchitis, emphysema, broncho-pneumonia, acute pleurisy, chronic diffuse nephritis, chronic interstitial splenitis, chronic gastritis.

The case illustrated the danger of using œsophageal bougies, however carefully they might be employed. A few years ago Dr. Jacobi presented to the Society a specimen removed from the body of a child, a few years of age, who had swallowed lye. The baby seemed to be doing fairly well, but all at once it died. A bougie had been introduced almost every day, and the child swallowed whiskey and milk quite well. One day pleurisy was diagnosticated.

The post-mortem revealed the fact that the bougie had broken through the mucous membrane, leaving an incomplete fistula which increased in size and finally perforated into the right pleural cavity, where, with the intense pleurisy, was found half a pint of the mixture of milk and whiskey.

Dr. H. Knapp presented

AN EYEBALL AFFECTED WITH CHOROIDO-CYCLITIS, PROBABLY CONGENITAL,

which he removed the day before from a woman thirty-seven years of age.

When she was six weeks old her parents noticed two black patches in the upper ciliary region. She could never see with that eye, but it gave her no trouble until three months ago, when the other eye became weak in sight and intolerant of light. This irritation having continued, the blind eye was removed. Before the operation it showed a dull and small cornea, two black elevations in the upper ciliary region, and an enlarged, irregular, and immovable pupil. Behind the transparent lens brownish masses projected into the vitreous, and were distinguishable from tumors only by their ill-defined superficies.

The globe was opened immediately after the enucleation. The vitreous was bloody and perfectly watery. The retina in the posterior half was so thin and firmly adherent to the highly atrophied choroid that only one blood-vessel betrayed its presence. The optic disk showed a marked glaucomatous excavation. The section of the optic nerve outside the eye was reddish. The subvaginal space was enlarged, and its soft trabecular tissue reddish and abundant. From the thickened and irregular ciliary region a thick pseudo-membrane stretched unbroken transversely through the globe. When it was incised serous liquid escaped. This condition is not rare in old degenerative processes of the eyeball.

The most remarkable feature of the case lies in the waking up of sympathetic irritations by a congenitally diseased eye after a quietude of thirty-seven years, during which time the morbid process, though steadily advancing, had caused no discomfort whatever.

Dr. Frank Ferguson presented fresh specimens which illustrated

[illegible]

They were removed from the body of a man, forty years of age, a native of Germany, who was admitted into the House of Relief, May 25, 1886.

According to the history obtained, for the last two days he had complained of rheumatism, and on the day of his admission, of pain in his stomach, for the relief of which he obtained medicine in a drug store. Soon afterward he was found unconscious and an ambulance was called. The patient was found in a comatose condition, the pupils finely contracted (nearly pin-point). Breathing full, very slow (fourteen per minute), and stertorous. Conjunctiva was insensitive, and it was impossible to arouse him. The patient was searched for the medicine, but it was not found. He was taken to the hospital as quickly as possible. Hypodermatic injection of tr. belladonna, ♏viij., was given, and cups applied to chest.

The patient was closely watched, but there was little improvement, and at 2.30 P.M., May 25th, he died.

He was three hours in the hospital. He had no elevation of temperature. He had no paralysis. His urine was not examined, and regarding him simply as a case of opium-poisoning his heart-sounds were not listened to. His pulse was forty to the minute.

Autopsy, twenty-four hours after death. The inspection of the body presented nothing unusual. The heart was large; there were long, thick, and broad vegetations attached to the cusps of the aortic valve. There was an ulcer one-eighth of an inch in diameter on the ventricular surface of the anterior segment of the mitral valve. The other valves were normal. There was no thickening or retraction of the affected cusps. The wall of the left ventricle was hypertrophied, the cavity dilated, muscular tissue soft and flabby, fibres granular, but no well-marked fatty degeneration. The lungs were intensely œdematous, and moderately congested. There was an infarction in the spleen, white in color, whose base was one and one-fourth inch in diameter; the apex of the infarction was directed toward the hilium of the organ. The kidneys showed signs of chronic diffuse nephritis; the cortices were thin, surfaces granular; there were cysts in cortices, and these organs were smaller than normal. The small blood-vessels showed marked thickening of their walls. There was increase in the fibrous tissue of the liver, with considerable fatty degeneration in the periphery of the lobules. Brain: The convolutions, especially those over the left parietal region, were markedly flattened. There was a large hemorrhage in the floor of the left lateral ventricle. There was recently coagulated blood in the lateral, third, and fourth ventricles. There was hemorrhage in the meshes of the pia-mater, and beneath this membrane, around the medulla, and on either side of the pons. The vessels at the base seemed normal.

The case was interesting to him, particularly, on account of the difficulty of diagnosis which arose between it and uræmic coma and alcoholism.

Dr. H. C. Coe said that the case reminded him of one of uræmic convulsions, in which he gave one-sixth of a grain of morphine hypodermatically, and about fifteen minutes afterward the patient became comatose, presented the appearance of one suffering from opium-poisoning, and died at the end of thirty-six hours. Before death, however, unmistakable signs of cerebral hemorrhage developed, and the autopsy revealed hemorrhage into the pons.

Dr. John C. Peters read a communication

ON GANGRENE,

received from Dr. Middleton Goldsmith, of Rutland, Vt., which was accepted and voted to be published with the proceedings, after which the Society went into executive session.

Correspondence.

ANTIPYRETICS IN FEVERS.

To the Editor of The Medical Record.

Sir: I am in the position of Dr. Fisher in last week's issue of The Record. *I* do not wish to "beard the lion in his den," but your denunciation, in the closing sentence of your editorial of May 22d, of antipyretics in continued fevers, should not pass without some protest against it. Clinical practical facts that will benefit our patients are what we are all after, and are much more convincing than any theoretical reasoning. And I believe careful bedside observation will prove to every practitioner that antipyretics are of the most undoubted benefit in continued fevers. A case of typhoid fever which I have just been attending will illustrate what I wish to say better than any argument that could be used. Therefore I wish to bring out one point in connection with the use of antipyretics, and at the same time urge upon the profession the use of, especially, antipyrin in controlling temperature. My patient (a man of extreme nervous temperament) ran a course of twenty-one days' duration. The evening temperature at the end of the first week was 103.5°. When the evening rise came he would commence tossing and turning in bed, constantly complaining because he could not sleep, and in this manner the nights would pass, and morning would find him completely exhausted. Sponging the surface and the list of hypnotics in full doses were all tried in vain. The thought came, reduce his temperature more thoroughly than can be done by sponging, and possibly he will sleep. Consequently, each evening, two fifteen-grain doses of antipyrin, at four-hour intervals, were given, reducing the temperature to 100.5°, and my patient obtaining from seven to eight hours' sleep, only waking to take his nourishment.

This was repeated each evening as long as necessary. From the time the antipyrin was commenced the case assumed a different aspect; the sleep seemed to rest and refresh my patient, and what promised in the outset to be a case difficult to manage seemed robbed of its severity and power to harm, it going on very pleasantly to a successful issue.

After reviewing my case carefully, I cannot help but feel that the antipyrin proved of inestimable benefit, and that your denunciation of antipyretics in continued fevers is a step in the wrong direction.

Very respectfully,

H. P. Chace, M.D.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 18 to July 24, 1886.

Perin, Colonel Glover, Assistant Surgeon-General. Leave of absence extended one month. S. O. 165, A. G. O., July 19, 1886.

Gardner, Major William H., Surgeon. Granted four months' leave, to take effect August 10th, or as soon thereafter as this services can be spared. S. O. 165, A. G. O., July 19, 1886.

De Witt, Major Calvin, Surgeon. Assigned to duty at Fort Sully, Dak. S. O. 66, Department of Dakota, July 14, 1886.

Dickson, Captain John M., Assistant Surgeon. Ordered from Alcatraz Island, Cal., to Fort Mason, Cal. S. O. 56, Department of California. July 8, 1886.

Cochran, Captain John J., Assistant Surgeon. Ordered from Fort Mason, Cal., to Presidio of San Francisco. S. O. 56, Department of California, July 8, 1886.

Gibson, Captain R. J., Assistant Surgeon. Ordered from Fort Winfield Scott, Cal., to Alcatraz Island, Cal., on return from leave of absence. S. O. 56, Department of California, July 8, 1886.

Kane, Captain J. J., Assistant Surgeon. Ordered from Fort Ringgold, Tex., to Fort Hancock, Tex. S. O. 85, Department of Texas, July 13, 1886.

Carter, Captain William F., Assistant Surgeon. Ordered from Fort Concho, Tex., to Fort Ringgold, Tex. S. O. 85, Department of Texas, July 13, 1886.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 24, 1886:

	Cases.	Deaths.
[illegible]	0	0
Typhoid fever	2	0
[illegible]	24	5
Cerebro-spinal menin[illegible]	2	2
[illegible]	35	13
[illegible]	80	45
[illegible]	1	0

Photographing the Womb.—A Swiss physician has described a method of dilating the uterus by means of tents, so that by means of a mirror a perfect view may be obtained of the interior of the organ. Not content, however, with a simple view, he is unselfish enough to desire to obtain photographs of the uterine interior in various diseases of the organ. *La Riforma Medica*, in commenting on this project, thinks the future of woman is sad indeed, if now her womb must not only be felt of, sounded, and measured, but photographed as well.

To Disguise the Taste of Quinine.—Honey is recommended by a writer in *The Lancet* as one of the best disguises of the taste of quinine, and especially valuable to this end when administering the drug to children. The dose should be placed in the centre of a teaspoonful of honey.

A Strange Tampon.—A writer in the *Deutsche Medicinal Zeitung* states that he was called to see a peasant woman in the country, who was suffering from hemorrhage from the genital organs. When he arrived he found her vagina filled with fresh horse manure, and the external genitals plastered over with the same material. The patient insisted that she wanted only some medicine, and would not permit the removal of the tampon. She shortly afterward had an attack of septicæmia.

THE TREATMENT OF HÆMORRHOIDS.

BY CHARLES B. KELSEY, M.D.,

NEW YORK.

THERE are, unfortunately, few diseases in which, as in hæmorrhoids, the surgeon is able to assure the patient in every case that he can positively be cured; and a definite and radical cure should always be the object of treatment, unless there is some very positive contraindication against anything approaching a surgical operation. There may be such serious and advanced organic disease in some other organ that even a comparatively trivial operation is not to be considered; but this is very rare. In such a case the patient must be content with palliative measures.

There seems to be a very wide-spread idea among the laity, for which they are generally prompt to give some medical authority, that when a patient has hæmorrhoids he had better bear the ills he has, lest, by being cured, he should incur worse ones. I have never been able to detect the slightest foundation of fact for this notion, and unless the patient is absolutely so far gone toward the grave that it is better to let him die in peace, unless so old and feeble that he cannot bear the least pain or shock, I always advise that he be radically cured of at least this one distressing and exhausting trouble.

The object of treatment is not only to cure, but accomplish this in the shortest time, and with the least suffering compatible with safety, and on this point the surgeon, and not the patient, must be the judge. There is, perhaps, no other disease on which the public consider themselves so well informed as this. They will not only diagnosticate their own condition, but, from newspaper advertisements, and the stories of their friends, they will decide upon their own method of treatment, and then give some chosen physician the opportunity to carry it out, if he is willing, according to their ideas.

Before undertaking any plan of treatment it will now generally have to be explained to the patient. So many "systems" have been advertised in this country; so much has been seen in the daily papers about cure "without knife, ligature, or caustic," and so much has actually been accomplished by the seemingly simple method of carbolic acid injections, that the practitioner will often find himself confronted with this ultimatum by his possible patient: "If you can cure me without an operation, all right; if not, I do not care to be treated." It may be possible and best to do as the patient desires, and cure him without what he considers an operation; but the relation between physician and patient should not be reversed by allowing the latter to dictate his own treatment.

That this is not a trifling matter the practitioners in our smaller cities and towns all know. Every few days they complain that they cannot treat their patients by operation on account of the competition of some quack who uses carbolic acid. For their benefit I have pretty thoroughly explained this method of treatment, and I shall speak of it again now. It is a good thing, but it is not always the best thing by any means, and the educated man, who has many ways at his control, will in the end get better results than the one who advertises his hypodermatic syringe and frequently does not know a hæmorrhoid from a cancer.

Before describing in detail some of the many methods of treating this affection, and discussing the relative merits of each, it will be necessary to distinguish with great clearness between the different varieties of the affection itself. There is no plan of treatment equally adapted to all cases, because hardly any two cases are alike; and the differences may be simple in degree or in kind.

The old division of hæmorrhoids into external and internal is useful, but is in many ways unsatisfactory. There are many varieties both of external and internal, and there is a distinct class which can scarcely be included in either, and which I have been in the habit of speaking of as intermediate.

Beginning with one form of the external trouble, the patient will give a history something like the following: He or she is in good health, and until a day or two past has never had any symptoms of rectal trouble. Quite suddenly, while about the usual occupations of the day, a sense of pain, just at the verge of the anus, is experienced, which steadily grows worse, until it becomes very troublesome. An examination is made by the sufferer, and a small, soft tumor is felt, which is very tender, and which disappears on pressure, but immediately reappears when the pressure is removed. It can be pushed within the sphincter, and the act gives relief, but it is down again in a moment.

After a few hours and some handling the patient is unable to sit with comfort; but the affair is so trivial that he does not care to go to bed, and so keeps around on his feet, and very likely applies Pond's Extract. After going to bed he feels better, and next morning imagines he is nearly well: but after an hour or two the pain is

worse than ever, and the tumor is larger, harder, and more sensitive than on the day before.

If an examination now be made an external hæmorrhoid of one variety will be found—such as is shown in Fig. 1.

The tumor will vary in size from a pea to a large grape, and is composed solely of blood clot. A small external hæmorrhoidal vein has ruptured, and blood has been extravasated in the delicate subcutaneous connective tissue. The blood shows black under the tightly stretched skin, and the pain is due to the tension.

There are two ways of treating such a tumor. The first and best is to lay it freely open and turn out the clot from its bed. The bistoury should be sharp-pointed and delicate, the tumor should be transfixed from the anal surface outward, and the incision should be in the line of the radiating folds. After such an incision the pain will almost instantly disappear. A little styptic cotton should be placed between the cut surfaces, a large towel folded into a pad applied to the part, and the patient told to sit upon a hard chair, with the compress under him, for fifteen minutes till there is no longer any oozing of blood. The subsequent treatment consists only in bathing with cold water two or three times a day, and the cut will be healed in three or four days.

This operation is so trivial and the relief so immediate that it is generally safe to perform it without any previous explanation to the sufferer; but should it not be permitted another plan must be followed. A cathartic containing podophyllin (pil. podophyllin co.) should be given at once, to secure two or three free actions of the bowels, the patient put upon his back on the bed or sofa, and a rubber ice-bag filled with finely powdered ice placed against the part, and kept there till the pain subsides. Cold usually gives great and immediate relief, but should it not, a poultice may be substituted. Under this plan of treatment the patient will probably be relieved in two or three days, so as to be able to get around with comfort, provided the clot is to be absorbed. In some cases, however, suppuration will occur, and in about a week from the time the swelling first appeared it will open spontaneously and discharge a few drops of pus, to the great relief of the patient. As soon as it becomes evident that this is to be the course of events, poultices should be applied and continued.

This form of hæmorrhoid is comparatively trivial, but it often causes great pain and confines the patient to the house for several days, and the suffering is often increased by improper attempts at treatment. Instead of being freely cut, they are often punctured with a needle by the patient. The result is the escape of a few drops of bloody serum, relief for an hour or more, and then renewed suffering, from the bruising and squeezing which usually attends this attempt at surgery. I have seen them leeched by physicians, with the result of starting a slight bleeding which continued for several days, without, however, giving any relief. They are not infrequently injected with carbolic acid by those who have heard of this method of treating hæmorrhoids, and it is only by great good luck that suppuration can be avoided after this has been done.

Those who have once been troubled with this form of hæmorrhoids are very liable to repeated attacks. The veins are delicate and feebly supported, and a little unusual strain upon them is sufficient to produce an extravasation. This may happen after a constipated passage, an interference with the perfect discharge of the hepatic functions, or from a cause too slight to attract the notice of the patient. The preventive treatment of this, and in fact of all other varieties, consists in the maintenance of as perfect a state of the general health as possible, perfect regularity in the action of the bowels, without straining, and the daily use of cold-water ablutions to the parts. Tobacco and alcohol must both be used in moderation if at all, over-eating must be avoided, and if a careful regulation of the diet will not suffice to produce a regular, daily, natural action of the bowels, a slight laxative must be taken daily. One who is in the habit of having a passage each morning may easily bring on an acute "attack of piles" in a few hours by going to business without taking time to attend to this function, and may be able to relieve it by an enema or a glass of mineral water almost as quickly.

All patients with any tendency toward hæmorrhoids should use cold water to the parts freely, at least once a day. In the morning before dressing, after the daily movement, or at night before retiring it is well to sit on the edge of the bath-tub, turn on the cold water, and with a large sponge apply it freely. The parts should not be rubbed either with the sponge or in drying with the towel; but the sponge full of water should be placed against the parts, and gently pressed out fifteen or twenty times. This is the best tonic, astringent, and anodyne of which I have any knowledge, and its habitual use would prevent a very considerable portion of all hæmorrhoidal difficulties.

The next variety of external hæmorrhoid differs in every respect from the last except in its position. This one contains few blood-vessels, and is composed almost entirely of skin and connective tissue. It is, in fact, a pendulous tag of skin attached to the margin of the anus as shown in Fig. 2.

Fig. 2.

Under ordinary circumstances it is not painful, and therefore the surgeon is not often consulted about it, except when it has begun to cause trouble. These tags of skin and connective tissue (often improperly called condylomata) assume many different shapes and sizes. They are often mere pendulous excrescences like the one shown in the bottom of the figure, nearly an inch long, and no larger than a crow-quill, and almost devoid of sensibility, having just sufficient blood-supply to support nutrition. Again, they are attached by a broad base, and two or three of them are joined at their bases, partly surrounding the circumference of the anus, but they still have little sensibility or vascularity. Sometimes one will be found which has become quite large and has an attachment nearly an inch long. Many of them are excoriated on the anal surface, and hence give rise to considerable serous discharge.

The origin of these tumors should be well understood. When found at the anus, in connection with a stricture of the rectum, they are supposed to indicate syphilis as the cause of the stricture. I have no faith in such a statement. To me they indicate nothing but a continued irritation of the outlet of the rectum. They are, according to my experience, as frequent in cancerous as in syphilitic stricture, and often as well developed when there is no serious rectal disease. The hæmorrhoid shown in the last figure, if allowed to run its own course, will make one of these tags. The blood-clot will gradually be absorbed, but not till it has caused a certain amount of inflammatory exudation and hypertrophy of the skin, which will ultimately show itself in the form of a cutaneous excrescence.

Again, this form of tumor is certainly indicative of

more serious disease within the rectum, and should always lead to careful examination. A prolonged sero-purulent discharge from the bowel is amply sufficient by its continued irritation to produce these tumors, but they will often be found without rectal disease, and with no history to account for their gradual formation.

It is safe to say that the surgeon will seldom be consulted for these tumors alone when they are quiescent—that is, when they are not acutely inflamed, and therefore cause no pain. But they are liable to become inflamed on very slight provocation. The same causes which will produce the last variety will cause acute inflammation and suppuration in this. Then the patient presents himself with much the same symptoms as in the last case, except that the pain has been more protracted, because the patient is more accustomed to the annoyance of the tumors and is slower to seek relief. The patient will come with the history that he has had piles for a long time, that they never go back, that generally they cause little annoyance, but for a week back he has had great pain, there has been considerable swelling, and he is unable to sit down with any comfort. An examination will reveal a hard, tender, somewhat œdematous mass of tissue just at the verge of the anus. Its attached base may surround nearly one-third of the anus and may be fully half an inch thick. It cannot be forced above the sphincter, or, at least, cannot be made to remain there. There may be two or three of these tumors. The outer surface is composed of skin, and the inner is smooth and shining, being composed in part of finer skin and in part of the mucous membrane in which the skin ends at the anus. It is plainly a connective-tissue tumor, having its attachment outside of the rectum, and not one composed of blood-vessels covered by the mucous membrane of the rectum.

It is necessary to be thus particular in the description of this form of hæmorrhoid because of the painful errors often seen in its treatment. It never, when uninflamed, belonged within the canal, and it naturally cannot be made to stay there by any amount of force when it is swollen to three times its usual size. It is not a vascular tumor to any extent, and therefore the leeching and scarifications often resorted to never give any relief, while the force used at attempted reductions, sometimes under ether, invariably makes matters worse. If allowed to take its own course it will seldom suppurate, but will gradually subside, and in a couple of weeks the pain will in great measure have disappeared, the tumor always, however, remaining somewhat larger than before the attack.

The treatment of this variety is essentially the same as last, although the cutting to be done is more considerable. It is particularly in this class of cases that cocaine may be used to the best advantage. If the base of the tumor be small, five drops of a four per cent. solution should be injected into it, and when it is no longer sensitive it may be seized with forceps and snipped off with strong scissors. There will be some bleeding, but generally only a little, and styptic cotton, with a compress and bandage, left on for a quarter of an hour will stop it. When the base is larger, say an inch or more in length, cocaine must be used at two or three points, and I prefer the clamp and cautery to the scissors. No after-dressing will then be necessary except cold water, or possibly a poultice to relieve pain. If the tumor be small, the patient will generally be free from pain and able to attend to his business on the following day. If it be larger, and the clamp has been used, it is better to keep him in bed for several days, with cold compresses or poultices to the wounds.

These operations are best performed when the tumors are quiescent and not acutely inflamed, as the pain will then be much less and the recovery much more speedy. But, unfortunately for the patient, he seldom wants anything done till he has had a good deal of suffering, and the doctor is seldom consulted, except during an attack of inflammation. Under such circumstances nothing is gained by waiting for the attack to subside, although the operator must allow for the infiltrated condition of the parts, and not remove enough skin to cause subsequent stricture.

One of the most extensive cases of this form of trouble I have ever seen is shown in Fig. 3. The patient was

under the care of Dr. Hemingway, of this city, with whom I operated in consultation. The man had had hæmorrhoids for years. About a week before I saw him he had been drinking hard, and had ended his spree with a heavy dose of cathartic pills. On waking in the morning he found his piles much worse than before, and entirely irreducible. On examination two hard, œdematous, intensely painful masses were found, forming a complete ridge around the anus, each about the size and shape of the thumb, and meeting in front and behind. They were covered externally by skin, and internally by the smooth, glistening mucous membrane of the verge of the anus. The finger introduced between them passed readily into the healthy rectum, but there was no sphincteric contraction appreciable.

On account of the extent of the disease the patient was treated for four days with absolute rest in bed, poultices, and anodyne applications, but without causing any decrease in the size of the tumors. He was then etherized, and the masses removed with the clamp and cautery. On account of their size, which was too great to permit of grasping the entire base in the clamp, each one was divided at the middle down to the margin of the anus, and clamped off in two sections—the cautery thus being used four times. After this the anus itself was burned through posteriorly and on each side, to cause future contraction of the orifice, for from the very dilated state of the anus and loss of power in the sphincter, there was reason to fear future prolapse after the hæmorrhoids were cured. The patient made a good recovery, with a tight sphincter.

I mention this case as an illustration of the proper method of treatment, though the condition was much more serious than will often be seen.

Supposing now that the patient declines operation, the case must be treated as follows: Absolute rest in bed, laxatives daily to keep the bowels free, an ointment of equal parts of extract of opium and extract of belladonna, with sufficient vaseline to render it soft kept constantly and freely smeared over the parts, and hot poultices constantly applied. By this means the inflammation will gradually subside, and in an ordinary case the patient will be around in a week or ten days. There is nothing else to be done. Attempts at reduction always do harm, and can by no possibility do good, and the same applies to leeching, scarification, and incision. Injections of carbolic acid will cause suppuration, and failing this, can only make the patient's condition more unendurable.

There is still another form of hæmorrhoid which is seldom or never described by writers, but which is still very frequent, and which generally puzzles the practitioner as

to its proper treatment. It may exist alone or in connection with other forms of the disease, and the surgeon, as a rule, will only be consulted about it by the better class of the community, who are in the habit of seeking advice early in the course of any trouble. It consists in a varicose condition of the veins just within and at the margin of the anus. Under ordinary conditions there is no tumor and no bleeding, but, when the patient strains, the veins in this locality swell up, are distinctly visible through the skin, and form a tumor of considerable size, but not well defined or limited, and having no pedicle. The tumor may be lateral or posterior, and there may be several of them. As soon as the straining stops the tumor subsides and disappears.

I have been called upon to treat this condition, existing without other disease, oftener, perhaps, in physicians and in very nervous patients than in any other class; though it is not infrequently united with other hæmorrhoidal tumors for which any patient may seek advice. As a rule, I think, when there is no other trouble it is better to treat it by cold applications and regulation of the bowels, as already described, than by a surgical operation. If, however, the patient be under ether for a more severe operation, it is generally easy to include enough of these tumors in the clamp or ligature to cure them at the same time. As there is no distinct mass to be removed, I never advise a cutting operation for these alone, and thus far have confined myself to one of two methods—the injection of carbolic acid and electrolysis. There seems to be little to choose between them; and yet, if preference is to be accorded to either, it is probably to the latter, on the ground that it is not likely to produce a slough.

If carbolic acid injections be used, the strength of the solution should not exceed ten per cent. of the pure acid. This will generally cause a smarting sensation for a few moments and no further trouble, while a thirty-three or fifty per cent. solution thrown into one of these veins, showing as a black line under the skin, will cause it to immediately change to a whitish hue, and a few days later the patient will appear with an ulcer of considerable size, which will take some weeks to heal. The idea is to produce induration without sloughing, and to be sure of doing this the injection must be weak and repeated several times at intervals.

Electrolysis is not generally very painful in its application, nor is the subsequent suffering very severe.

In the use of the electrolysis a current should be secured sufficient to cause coagulation in the white of an egg in a glass. The positive electrode should be a fine cambric needle, introduced into the centre of the tumor. A sponge over the buttock or sacrum answers for the negative. Cocaine may first be injected into the tumor with advantage, and the positive needle should be introduced and separated from surrounding parts before the negative is applied. The current should be passed for at least ten minutes, and after a short time the cautery action at the point where the needle pierces the tumor will be plainly visible. There will be some pain at the time of the operation, and perhaps considerable on the following day, but after this the tumor will be found considerably reduced in size.

Coming now to those hæmorrhoids which arise within the rectum, and not from the outer margin of the anus, we will first consider the capillary variety. In this there is often no appreciable tumor, but rather a strawberry-like surface, slightly raised above the surrounding level, about half an inch in diameter, and bleeding very freely, often *per saltum* on the slightest provocation.

The following case, seen by me with Dr. Watson, of Jersey City, will illustrate this form of disease and the appropriate treatment:

The patient, a lady, thirty-five years of age, had been married fifteen years, and ever since marriage had been troubled with occasional profuse rectal bleeding. As much as half a pint of arterial blood is said to have passed at a time. There had never been any protrusion, and the blood was passed, not with the stool, but some time after by itself. Frequent rectal examinations by the finger had failed to detect anything abnormal, and arrangements had been made for complete dilatation and examination under ether. Before doing this the usual inspection of the parts was made by gently pulling down and opening out the folds of the anus, and just within it was detected the bright red, slightly raised mass of blood-vessels, which, to my mind, was sufficient explanation of the history. Without making a complete examination of the whole rectum, it was decided first to cure this, and two thorough applications of strong nitric acid, Dr. Watson tells me, entirely stopped the hemorrhage.

This is the only form of hæmorrhoid in which applications of nitric acid will be likely to result in permanent cure, and in this it works so well that it is hardly worth while to try other things. If the application be made thoroughly to the whole surface, a single one will be all that is necessary, in most cases, to entirely cure the disease.

The only other cases in which I use nitric acid are those of well-marked internal hæmorrhoids which bleed freely at stool when protruded, and in which for any reason it is unadvisable to attempt a radical cure. By touching the surface of these tumors with strong acid the bleeding may cease entirely for a considerable time, and the tumors may even diminish in size.

There are cases of internal hæmorrhoids in which no cautious surgeon cares to operate, but they are not frequent. Operative treatment is almost invariably successful and the risks are very slight, while palliative treatment is exceedingly unsatisfactory in its results. Age alone seldom contraindicates an operation, but advanced organic disease of any sort may do so. It is not well, as a rule, to operate for hæmorrhoids which are due to pregnancy, until some weeks after delivery, when the uterus has returned to nearly its normal size. Again, I have grown a little cautious about submitting patients from the country to severe operations, involving protracted confinement to bed in New York during the hot months, and prefer to have the operation performed at some of the neighboring seaside hotels, where cool nights can be assured. With a strong patient in good condition this is not a matter of much importance, but with one, say seventy years of age, the operator must take every advantage if he wishes to avoid anxiety. In the vast majority of cases, however, it is safe to undertake a radical cure by one method or another, and in the few cases where this is not considered best the patient can generally be made more or less comfortable by palliative measures.

In my own practice ointments and suppositories have very little place in treating internal hæmorrhoids, and rectal supporters have none at all. The line of treatment has already been alluded to. Perfect daily regularity in the movement of the bowels and the free use of cold water applications are worthy of the greatest reliance. The latter will be found a much more effective astringent than either tannin or iron.

It is sometimes necessary to treat a patient with internal hæmorrhoids for the complication of strangulation when he is unwilling to submit to anything looking toward radical cure. His piles, owing to some accident, some nervous strain, or irregularity in living, are down, have been down a day or two, and no manipulation on his part will put them back. Examination shows them to be exquisitely sensitive, engorged, and possibly even gangrenous, and the sphincter grasps them with a power which cannot be overcome. This extremity may be the doctor's opportunity, and many a patient is willing to be radically cured after forty-eight hours of such suffering, who has always been too timid before. Under such circumstances nothing is to be feared from an operation, and nothing to be gained by delay. The patient should be etherized, and the tumors removed with the clamp and cautery. The cure will be as rapid as under ordinary circum-

stances. Should, however, the patient still object to radical treatment, the following is the best course of procedure. Place him on his face, with a hard pillow under the pelvis, smear the whole mass and the right hand freely with olive oil, cover the tumors completely with the fingers, and make gentle and firm pressure on the whole mass at once till a part of it slips up the bowel. If a single tumor will give place the others will soon follow.

This is not a matter of half an hour but of one minute. If it does not succeed at the first attempt, it probably will not at all; and the next step is to give ether to the point of primary anæsthesia and forcibly reduce the mass. With ether internal hæmorrhoids can always be reduced when strangulated by a tight sphincter. Should the patient object to this, there is nothing to do but leave him in bed with ice to the parts, and the ointment of opium and belladonna freely applied. The tumors may slough at one or two points even without the ice, and the ice must not be pushed too far on this account; but sloughing under these circumstances is one of nature's means toward a partial cure. Generally after a couple of days' rest in bed the patient will be able to reduce the tumors for himself.

We come now, naturally, to the question of the best way of radically curing internal hæmorrhoids. Of all the methods known to surgery it is unnecessary to deal with more than three—the ligature, the clamp and cautery, and the injection of carbolic acid. These are not enumerated in the order of merit, for no one method is equally adapted to all cases, and the operator will get the most satisfactory results who learns to choose wisely between them in each case as it presents itself.

The question resolves itself very readily to this, and the patient may choose. If he is willing to rest in his room for a few days and take ether, he may be entirely cured by a single operation, without more than a couple of hours' discomfort after coming out of the ether, and perhaps without even that. If, on the other hand, he prefers a treatment of indefinite duration, attended, probably, by a great deal more pain in the end, but for which it will not be necessary to take ether or be confined to the house (probably), he may be equally cured by that. The cure will be equally satisfactory to the patient for a time in either case, but more satisfactory to the operator in the former, because he is sure the disease cannot return, as it may, in a measure, after the treatment by injections.

Between the operation by ligature, and that by clamp and cautery, each practitioner must choose for himself. As far as safety goes, they are about on a par. There is no obvious reason why one should be more dangerous than the other, and an equal number of cases of each would probably prove that neither has much advantage in this regard. Either one may also be relied upon for a certain cure in every case when properly performed. But outside of these two points the operation with the clamp and cautery will give the greater satisfaction to the patient, and hence to the surgeon. Their relative advantages are to be judged from several standards. First, in the amount of pain the patient has to endure after the operation. In the ligature this is often protracted and severe. I have known it to be almost incessant, demanding the constant exhibition of morphine for a week, and the presence of the ligature surrounding more or less living tissue, and probably nerve-filaments, has been to me an all-sufficient explanation. It may be taken as a rule, that a ligature around any tissue within the grasp of the sphincter, no matter how thoroughly the skin may have been cut through before its application, or how tightly it may have been drawn, will give pain, and in this operation one or more ligatures almost always are within the grasp of the muscle. If they are fairly above the sphincters they will be less troublesome, but their presence has seemed to me to account for spasm of the levator, which is about as painful. No matter, however, to what the pain is due, its presence has been a very positive fact in many of my own cases; whereas with the clamp and cautery exactly the opposite has come to be the rule. In this there is no foreign body to act as a source of irritation and muscular spasm. The pedicle is first crushed and then cauterized to a dead and insensitive mass, and all that is left within the rectum is a charred stump. Patients tell me again and again that after the immediate effects of the operation have passed off, that is, in a couple of hours, they felt only a sense of soreness; that, in fact, they are more comfortable after the operation than they usually are after a movement of the bowels, and on the day following they are generally perfectly comfortable, so much so that they begin to want to know why they must stay in bed. Seldom with Smith's operation (that with the clamp) is it necessary to give any morphine except the suppository placed in the rectum immediately after the operation. I can only say that this has not been my own experience with Allingham's operation (that with the ligature), and I refer to exactly parallel cases as to the amount and situation of the tumors removed. The ligature is generally the means employed in New York, and the experience of nurses who have attended such cases and are called upon to care for a patient, after the clamp operation, is often amusing. In the former they will have plenty to do, in the latter nothing.

Again, after the ligature there is very apt to be retention of urine; with the clamp almost never; and this is in itself a great advantage. There is also much less constitutional disturbance after the latter than the former. Not infrequently a male patient will enjoy his cigar after breakfast on the day following the operation, which is a fair test of his general condition.

Another point of great importance to the patient is the length of time he is to be confined to his room and bed, and here again the advantage is in favor of the clamp. Very exceptionally does this method keep the patient confined after the tenth day, and in my last operation the man returned to his home in a distant city on the eighth, with perfect comfort, having then been down to his meals in the hotel for two days before, and about his room since the second day after. In the case preceding that, the lady sat up on the day following, amused herself with the dress-maker after the third day, and left for a pleasure trip on the tenth, assuring me that *at no time* since the operation had she suffered as much discomfort as she usually suffered every day before. In comparison with this it is only necessary to remember that the ligatures do not generally all come away before the tenth day, and that up to this time the patient usually manifests but little desire to be about.

These, in brief, are the advantages of the clamp. Now a few words as to the details of the two operations. Both may be done painlessly with cocaine, but where the operation is extensive, and much tissue is to be removed, it will not generally be found entirely satisfactory. The free nerve-supply of the anus and the difficulty of bringing all the nerves into contact with the solution are the probable explanations of the frequent disappointments attending the use of the drug in operations on this part. Where a single circumscribed tumor is to be removed, it will generally act with perfect satisfaction, because it can be placed exactly where it is needed. Where the whole circumference of the anus, and the rectum for a considerable extent, is implicated, and where it is necessary to dilate the sphincter thoroughly, I have more than once been disappointed in its use, some parts being insensitive, and others by no means so; and this after crowding a four per cent. solution injected hypodermatically at every point which was to be operated upon, to the extent of producing decided constitutional symptoms. In any extensive operation by either method, ether will be likely to be more satisfactory. In some cases, where the pedicle of the tumor is well above the sphincter, and no skin at the margin of the anus is involved, the operation may be done without any anæsthetic; but this applies rather to

cases where a single tumor only is to be removed; and does away with the chance to thoroughly stretch the sphincter, which is always to be recommended.

In both operations the bowels should be moved two or three times on the morning of the day of operation, by a laxative taken before going to bed the night before, and the rectum should be washed out by an enema an hour before operating.

After neither operation should the bowels be confined more than fifty-six hours, and the first movement should be rendered easy by a repetition of the laxative on the night before. This is contrary to the general practice and is a great improvement, as is easily proved by a few trials of the two plans. If the bowels are confined till the tenth day, great pain will be the invariable result of the first motion. The fæces have become hard and voluminous, and the parts are not yet healed. Great straining and suffering are the necessary consequences. Moreover, nothing is gained. The wounds heal no more quickly for the constipation, if as quickly, and the idea that the passages may in some way cause them harm is not founded in fact. By the other plan an easy, natural motion is secured on the third day, which is attended by little or no pain; the rectum is thoroughly cleansed, not only of fæces but of blood and discharges, in the most natural and effectual way; there is less danger of absorption of offensive matter, and the patient, if one of regular habits, feels much better in every way. After the first motion a gentle laxative should be given every night, for ten days longer, to secure one easy, natural passage daily.

After the operation the patient may usually consult his or her own appetite as regards diet. Nothing reasonable need be denied—another point gained by getting the bowels into regular working order.

It is not advisable to allow too much freedom of exercise till the wounds are entirely healed, lest granulation and cicatrization should be delayed. The difficulty with the clamp operation, however, will be to keep the patients from active motion. Ten days of rest will generally be all-sufficient, after which comparative quiet should be observed for another week.

Only a few words will be necessary regarding the details of the operations, so well are they generally understood. Everyone has his favorite instruments, and for my own work I have somewhat, though not to any great extent, modified those of Smith. The clamp which I use has no ivory guards, has a saw edge on both blades, and has handles which give much greater power than the scissor-like rings of his instrument.

Fig. 1.

With this handle the screw pressure is not necessary. The tumor is isolated with long-handled, tooth-sharp hook-forceps, the clamp is applied and held firmly in the left hand, the tissue to be removed is cut off with curved scissors, and Paquelin's cautery applied to the stump, all in this order and very rapidly. The pressure to the clamp being applied only by the hand, can easily be released to test the efficacy of the cauterization, without the use of the other hand to release the screw, and can as easily be renewed, if necessary, without laying down the cautery iron.

The most delicate point in the operation is to decide just how much tissue to include in the clamp, and this can only be learned by experience. If too little be removed the anus may be left surrounded by unsightly tags, which will be a source of future annoyance; and if too much, an undue amount of contraction may result. After the clamp is in place the part must not be cut off too close to it, but a good stump should be left for the action of the cautery. This should be thoroughly applied over the entire cut surface at a reddish-black heat. The clamp may then be loosened a little, and if any bleeding point appears on the charred surface it must be tightened again, and the cautery reapplied to the bleeding point till the clamp can be removed and the surface remain perfectly dry. The clamp while in place will stop all hemorrhage, but it does not crush the vessels, and they will bleed again as soon as it is removed, unless their mouths be thoroughly closed by the cautery. A grain of opium and half a grain of belladonna, in suppository, should be introduced after the operation, and no dressing will be necessary unless there be some oozing of blood from the points where the scissors have been used in the skin to make a groove for the clamp. Then a pad and bandage may be applied for a few hours, after which all that will be necessary is a little absorbent cotton smeared with vaseline.

The method of carbolic-acid injections can only accomplish by repeated operations what the clamp and cautery does by a single one. Each injection is a surgical operation, and may cause greater pain and longer confinement by its effect upon a single hæmorrhoid than the operation with the clamp will entail in effecting a radical cure of the disease. I do not mean to say that this will be the case, only it may be, and the operator must be prepared for it. This is in itself a great objection. It prevents the surgeon from giving any positive prognosis as to the time necessary for a cure, or as to the amount of trouble, pain, and confinement the patient will have to endure. All he can promise is a cure in the end, and one which, if things go well, will be very satisfactory, in that it involves nothing that the patient considers a surgical operation, and no confinement to the house. He cannot, however, promise that things will go well.

Perhaps this point may be illustrated more clearly by the report of three or four typical cases.

A maiden lady, aged forty, very nervous, and in feeble health, is suffering from four hæmorrhoids. They spring from above the sphincter, come down and bleed at stool, are easily replaced, are distinct each from the other, do not involve the margin of the anus, and are not larger than so many cherries. The case is favorable for injections, and one of fifteen per cent. carbolic acid is made, causing a smart pain at the moment, which soon passes away. Four days later she says she had considerable soreness for a couple of days after the first injection, but does not complain, and a fifty per cent. solution is placed in another tumor. On the next visit she gives the same story, but finds herself decidedly better as to the size of the protrusion and the bleeding, and is much encouraged. Another tumor is brought down and injected exactly as the last, but the immediate pain is more severe. At the next visit her physician tells me he had a good deal of trouble after the last operation; was sent for in the evening and had to give several opium suppositories during that night and the following day. The patient was in bed for three days, but is all right again now. She herself says that the pain has not yet entirely disappeared, and is anxious to know if she must have as much suffering during the remainder of the treatment. It is decided not to make an injection at that visit, but after a few days more it is done. The patient this time is nervous and timid, and a suppository is given at the time. There is pain for a day or two, not as bad as the last, and the case is cured. Ten days later she is entirely satisfied with the result; there is no longer any bleeding or protrusion, and she is so glad she "didn't have to undergo any surgical operation."

This is an average favorable case of a mild form of the trouble. The patient, family, and family physician are all delighted with carbolic acid, but a little thought brings out the following facts: She was under treatment

six weeks, and most of that time, though it might not perhaps have been necessary, she remained in the house. During this time she was in bed and suffering pain at least one week. She took considerable quantities of opium and bella-donna. On the whole, she gained nothing by this treatment over that with the clamp, except that she did not take ether and was spared what she greatly feared, a surgical operation. But this, in such a case, is an advantage not to be despised by the laity, no matter how it may appear to the surgeon. It is, in fact, exactly on this inborn dread of an operation that the whole treatment by injections has been built up and still flourishes; and it is often surprising how well satisfied a patient will be to endure a great deal of unnecessary suffering, if by it he or she can escape the knife.

I have given this case as an average successful one. Many will do better, and as many more will do worse. A strong man will have more pain and not lose a day from his business; another will complain only of pain for a couple of hours after the operation; but as far as my experience goes, all suffer in a greater or less degree at some time during the treatment.

Let us take now another case. A man of about sixty has had hæmorrhoids for twenty years. He is of sedentary habits and nervous, but with no other disease than the tumors. An examination shows a very advanced case of long-standing trouble. The tumors can be divided into four chief ones—one posterior, one anterior, and one on each side; but two of these are as large as hen's eggs, and the others only a trifle smaller. They spring from above the sphincter, and are entirely covered by mucous membrane; the sphincter is so relaxed that they protrude with the slightest exertion, and the patient has worn a rectal supporter for years.

It is a beautiful case for the clamp, and fit for that only; but at the outset I am met fairly by the not infrequent obstacle—"no operation." Argument is useless; he has heard of carbolic acid; in fact, his physician has sent him to me for that treatment, and it is that or nothing. Unwillingly I consent.

An injection of thirty-three per cent. is made posteriorly, and with the usual caution and instruction the patient goes home. Two days later he returns. He has had pain—yes, considerable; but he does not mind the pain as long as he can get well. Another injection of the same strength on the left side.

It is four days before he again appears, and they have been passed mostly in bed, and he has used several suppositories, but he is now better, and "if it is no worse than this he can stand it." The tumor injected last time is much smaller, but the posterior one, which was first attacked, is not much benefited, and five drops of pure acid are placed in its centre.

Three days later he reports that he is beginning to be better, that there is less protrusion at stool, and he has left off his supporter. The last injection has not caused a slough, but a hard inflammatory induration in the centre of the tumor. Another five drops of pure acid are injected into the same mass at a little distance from the hard spot, and he then tells me that ever since his last visit he has had considerable difficulty in passing water, which is high-colored and diminished in amount.

Four days later, says he had no very severe pain after the last application, and straining at stool fails to bring down either of the tumors which have been operated upon. Another injection of pure acid into the anterior tumor, the largest of them all. Three days later he reminds me that he is in a great hurry to go away on business, and is anxious to have treatment crowded more rapidly. Had no pain at all after last injection, and fears I did not get it in. The injection has again caused a hard lump of inflammatory induration, but no slough, and a decrease of about one-third in the size of the mass. There is still more work to be done on the first one, and another five drops of pure acid are injected into it, causing no pain at the time, or after, as he tells me two days later.

Thus far all had gone well, and three of the tumors had been treated without accident. An injection of pure acid was made into the last one, that on the right side. Three days later I am sent for to come to him. Before this he has come to me, but he has been in bed ever since the last injection; the urine has been very scanty and passed with difficulty; there is an enlarged and painful gland in the right groin; and a painful swelling at the verge of the anus on the right side, circumscribed, the size of an almond. Eleven days later, the patient being still confined in bed, the abscess at the margin of the anus was opened and a drachm or so of pus evacuated. A couple of days later it was found to have also opened spontaneously on the mucous side of the swelling, just within the sphincter. Ten days later this was healed. The patient had then been under treatment just forty days. He was much better; the tumors were all considerably reduced in size, they still protruded at stool, but went back spontaneously, and he promised to report again in a few days. He never did.

This may be put down as a bad case. The only other one I ever have had came to me, by a strange coincidence, on the same morning, and the two between them cost me a summer's vacation. It is only fair to the method to say, however, that while treating this last one, I was carrying another gentleman, two years older, through the same process, whose tumors were, if possible, even more voluminous, and who was entirely and satisfactorily cured by six injections during fourteen days. He was a man of hardier constitution and greater nerve.

In my other bad case an injection of the acid into a small tumor, just within the sphincter, was followed by a severe ischio-rectal abscess, lymphangitis running up the rectum, and enlarged glands in both groins. After the rather diffuse phlegmon had limited itself, the usual operation for large abscess in this region was performed; but the incision had to be carried into the bowel, and the patient only recovered after weeks of treatment.

Out of many hundred injections of carbolic acid this is my only really unfortunate case, the others have been satisfactory in doing what they were intended to do, and, perhaps, this is no greater a proportion than could fairly be counted on in any surgical procedure. The method can hardly be considered a dangerous one, or else it would more often be heard from in the hands of the ignorant pretenders who succeed in living by practising it. As to the details of its application, I have already said enough in former communications; we are now more especially interested in its comparative advantages and disadvantages.

In the first place, there is no doubt that by using it with sufficient thoroughness a cure can be obtained in every case. But, on the other hand, a hæmorrhoid which has simply been deprived of a part of its vascular supply, and, in consequence, has become so small and hard that it neither bleeds nor protrudes, is not as radically cured as one which has been entirely removed, nor has the surgeon the same confidence that it will never recur. Where ulceration and sloughing are produced by the injections the case is different, for then there is an actual loss of tissue, accomplishing the same end as the clamp or ligature.

When a slough is produced the patient will have more pain, and often will be confined in the house a longer time than after the clamp operation. A single slough will do this, and yet several may be produced in a single case before the cure is complete.

These ulcers heal spontaneously as a rule, but not as quickly as do the wounds made by the clamp and cautery or the ligature.

It is impossible to tell in any given case whether an ulcer will be produced or not; and as the amount of pain and the length of the treatment depend almost entirely upon this point, it is equally impossible to give the patient anything but an approximate guess as to these things. This will be found [illegible] of a great

practical objection, for the matter of time is often very important. With the clamp the patient may be safely assured that he need not remain in the city more than ten days or a fortnight at most; with injections no such assurance can be given. Sloughs are certainly, as far as my experience goes, almost entirely independent of the strength of the solution or the dissolving medium, and I have experimented with every strength from ten per cent. to pure acid, and with various media. Sperm oil is supposed to be less irritating than glycerine, but I have not found it so, and it is much less agreeable to handle. Neither does pure almond oil seem to possess any advantage. As seen in one of the cases reported in full, pure acid failed again and again to set up a slough, and yet a ten per cent. solution of the acid will do it not infrequently, and so will the pure. The stronger injections cause no more immediate pain than the weak, and the subsequent pain, when no slough is produced, is not generally very prolonged. The most frequent report is that it began two or three hours after the injection, and was pretty severe for a few hours, then passed away. Sometimes it does not come at all.

There is another complication that I dread more than sloughing, though the latter can hardly be called a complication, and that is small marginal abscesses, such as is described in the second case. This will appear within two or three days as a painful tumor just at the verge of the anus, distinctly circumscribed, not much larger than a large grape, projecting sharply from the surface; and it is really an external cutaneous hæmorrhoid caused by the irritation of the work going on in the rectum above, and it will almost invariably suppurate. This means about ten days of sharp pain, worse than that caused by the injection of internal tumors, even when they slough, and it requires a good deal of nerve for a patient to keep about under these circumstances. It should be poulticed and incised as soon as pus is formed. If allowed to discharge itself it will break frequently on both cutaneous and mucous surfaces, and a small bridge of tissue will be left between the two openings, which should be made into one with knife or scissors. This is not serious—nor is it pleasant. When the patient is well he forgets it and is satisfied; and yet it was the last straw that cost me my patient in the second case.

This form of trouble is due to irritation higher up, but if hæmorrhoids at the verge of the anus, covered with skin on the outer aspect, be injected, they will also suppurate in the same way.

There is one more objection to this method which I cannot but think is more theoretical than practical. It is claimed that starting an inflammatory process in a tumor still connected with the general circulation, and with no precautions to limit the process, is in itself dangerous and liable to set up phlebitis or cause embolus. This, of course, may happen, but as a matter of fact it does not, any more than it does in the somewhat analogous operation upon nævi of the scalp with the hot needle. An injection of pure carbolic acid, or even of fifty per cent., destroys whatever it touches in the animal tissues, and the extent of the process very quickly limits itself. Even fifteen per cent. placed in a large vein at the anus causes instant coagulation, entirely stopping the circulation, and a ligature around the vessel could hardly do more.

To sum up, now, with regard to this method. In many cases it will give perfect satisfaction, and the patient avoids the operation which he fears. It is best adapted to small or medium-sized tumors which are distinctly pedunculated and spring from the rectum above the sphincters. In cases involving the margin of the anus and implicating the skin it will greatly reduce the size of the tumors, but it does not give as perfect a result as an operation by which the redundant tissue is actually taken away. In cases of extensive disease it will effect a cure, but the process is liable to be attended by more suffering in the aggregate, and to take much more time than either the ligature or the clamp.

There is an exaggerated idea in the minds of many practitioners regarding the harmlessness and freedom from accident of this plan of treatment. One of them related to me, not long since, how by invitation he spent half a day in the office of a celebrated travelling rectal specialist, who received his medical training in the dry-goods business, and watched him inject hæmorrhoids with a secret remedy. The patients came in from all directions, and the story was invariably the same—no pain at any time, no complications or accidents, nothing but the most perfect satisfaction and cure. The explanation is probably that the dissatisfied ones did not return. At all events, surgeons of repute in this country and abroad cannot boast of such eminent success.

Since cocaine became known I have tried many experiments in treating hæmorrhoids by various methods. One has been to snare them off with a small écraseur and silk salmon line, which is strong enough to cut through any tissue except bone, taking them one at a time, and doing it in my office. Many times I have ligated large tumors without feeling it necessary to inform the patient. Unfortunately the clamp and cautery cannot be used without the patient's knowledge. Sometimes I have thrown around a temporary ligature, and after drawing it lightly have injected carbolic acid, and after several minutes have taken the ligature away. Once or twice I have crushed the tumors. But all these methods of treating hæmorrhoids piecemeal are more or less unsatisfactory, and can only be recommended as substitutes for the better operation with the clamp.

After all has been said, I can only add that the most satisfactory cases of hæmorrhoids, of moderate or great severity, which come to my notice, are those in which the patient says at the outset, "Cure me as you think best." In them I use the clamp and cautery. They seldom cause a moment's uneasiness, and the result is always very gratifying.

The Madison, 25 Madison Ave., Madison Square.

THE CLOSURE OF CLEFT OF THE HARD AND SOFT PALATE, AT A SINGLE OPERATION, WITH A BRIEF REPORT OF A RECENT CASE.

By W. R. WHITEHEAD, M.D. (University of Paris), Denver, Col.

Ex-Resident [illegible] Medical Society; late Demonstrator of Anatomy in the [illegible] Department of the University of Denver and of the [illegible] University [illegible], Ex-Resident [illegible].

It is in fact largely from a sense of duty that I write this article, as the defender of a very useful operation for cleft palate, which, in my opinion, has been neglected, and which should be better understood and more extensively known, and which in more skilful hands than my own, and with less experience, would produce equally as good results, if not better.

It is useless to deny that the operation for cleft palate is a most delicate, difficult, and complicated one; but, notwithstanding, its exact and successful performance is within the reach of any intelligent and painstaking surgeon, once that the proper method be adopted and thoroughly understood. If some eminent surgeons have not met with desirable success, it is, I believe, because they have not given that careful attention and time to its study that possibly has distinguished their efforts in other directions. It should never be lost sight of that there are some fundamental facts underlying success in this operation, as in others, which cannot be ignored or lightly passed over, and one of these is that the muscles should be completely cut, and herein is where I find Dr. George Arthur so radically in error, and who does not tell us that he has ever attempted on the living subject the operation which he proposes by such profuse illustration.[1]

[1] See Medical [illegible], [illegible] review.

He proposes to combine mechanical and surgical methods to obtain better articulation. The mechanical method I shall not discuss, because I have disposed of that elsewhere (see Am[illegible] Journal of Syphilis). This mechanical method is an expensive and most unsatisfactory makeshift, especially in a growing child, and which should be entirely superseded by the permanent obturation of the cleft with the patient's own flesh by the proper surgical method.

Dr. Arthur's operation appears to be utterly impracticable, and if the mechanical part of his treatment depends on his operation, it must completely fail. He says: "The first step in the treatment is to unite the two halves of the uvula and soft palate as completely as possible. This may be done," he observes, "by freshening their edges and securing them together with sutures, preferably the perforated-shot suture." Now, he says nothing about first cutting the palate muscles to keep them quiet, and thus prevent by their constant action the sutures from cutting out in twenty-four hours, or in less time, and which they will inevitably do. But, continues Dr. Arthur: "If the cleft is too wide for this to be done without undue tension of the parts, small portions of the posterior and internal borders of the free edges of the palatine processes, large enough only to furnish secure support for a silver wire to be passed through perforations drilled through their centres for the purpose, may be cut off with a fine, sharp chisel under the mucous membrane, which should be completely separated from their inferior surfaces with the periosteum, or fractured off after suitable guiding perforations have been made, as shown in Fig. 1" (see his article cited). "These fragments," he remarks, "should be brought close enough together with a strong wire to relieve the wound of tension." These little square pieces of bone, which the doctor proposes to detach and denude of the periosteum on their under surfaces, would be deprived of most, if not all, of their blood-supply, and inevitably necrose. Besides, what is this done for? Simply with the theoretical idea that these pieces of bone will give support to the muscles of the velum. He tells us further on that no attempt is made to close the hard palate, this being left to the dentist. In view of the successful and striking cases which I exhibited to large numbers of surgeons and physicians in New York City, some years ago, before the old New York Medical Library and Journal Association, it is somewhat surprising to me that my modification and improvement of Langenbeck's operation for muco-periosteal uranoplasty should be so little remembered and understood, and hence I feel that this paper is not without some value. Besides, while in common with most people I am mistrustful of too much self-assertion, for which surgeons, more than physicians, are somewhat noted; yet there are occasions when too much modesty ceases to be a virtue, and I certainly feel now that I am not too self-asserting when I claim, what facts fully support me in saying, notwithstanding my limited experience of only about one dozen cases of successful closure of the hard and soft palate at a single operation, this exceeds the recorded cases of anyone in the United States, and, indeed, I believe of any three surgeons in this country. Why this is the case for so valuable and useful an operation space will not permit me now to discuss.

Further on in his article Dr. Arthur goes on to say: "If the above proceeding fails to relieve all tension on the wound, incisions, partly or entirely severing the tensors and levators, as recommended by Langenbeck, may be made (Fig. 1, *a*, *a*)." See Dr. Arthur's article cited, and in his Fig. 1, at *a*, *a*, opposite the first two molar teeth, marks which show cuts for the *supposed* section of the tensors and levators of the palate. Certainly Langenbeck must have been badly misrepresented, or the drawings are very much wrong, or Dr. Arthur is considerably out of the way in his anatomy of the palate muscles. However, I cannot believe this last, because he discusses very intelligently the action of the superior constrictor of the pharynx. But the importance of this last muscle in its action, I believe, has been generally much exaggerated as regards its useful effects on the velum palati after an operation for cleft palate.

Below I give a very brief report of a case of cleft palate which I closed on the day that I read Dr. Arthur's article—that is, on the 24th of last February. The case was of a little boy, named Harry Ashton, of Denver, three years old, and the dimensions of the cleft are shown in the accompanying kaolatype, Fig. 1.

The cleft was completely closed at a single operation, and now, on the ninth day, Dr. Dougan being present, the union is complete throughout the entire length; but I shall not remove the soft silver-wire sutures, of perfectly pure silver, until about the fourteenth day, and then allow the side-cuts to heal up. Afterward I shall operate on the lip, which is also fissured. The same method that I have so fully described elsewhere was here repeated. I was assisted by Drs. Dougan, Carlin, and Durbin, of Denver, and also most ably aided by Dr. Norman, an excellent dentist, of Denver, who lent me a dental chair, and which I always prefer to use in this operation when possible. I used my gag, and during the entire period of the operation it was retained in the boy's mouth, who was fully etherized most of the time. (See woodcuts of my gag, at *a* and *b*, Fig. 3.)

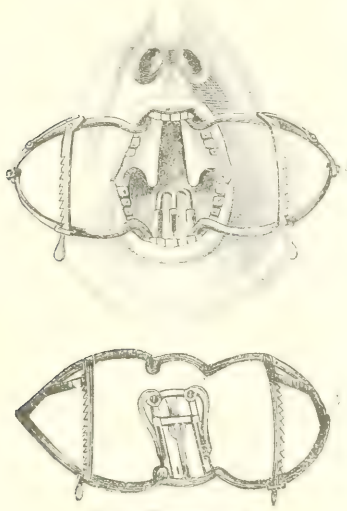
On the ninth day after this operation, and at which time this report was written, it was not thought necessary, as affecting the result of the operation, to notice a little mishap which occurred during the operation, and which was the accidental detachment, with the periosteal elevator, of the anterior part of one of the flaps. Perfect and firm union had already occurred the entire length of the sutured flaps; but subsequently retraction of the detached flap near the front part of the former cleft, and near the incisor teeth, left an opening at one of the side-cuts of the size represented at Fig. 2.

Fig. 2.

I attempted, some weeks afterward, when I operated on the harelip, to close this small opening; but the extreme friability of the thick, vascular, muco-periosteal tissue of the palatine vault at this young age, made the flap on one side tear or break across like wet blotting-paper, and I desisted from the operation. With the cleft nearly closed, and the lip now in natural shape, the result is good; besides, the speech is improved. This little mishap, while it prevented the operation on the palate from being a perfectly complete success, yet adds greatly to the interest of this operation as a part of its history, briefly summed up in the following practical experience: If the attempt is made to close by operation a hole in the palatine vault of a child, this can only be done under the same conditions as the closure of an extensive cleft; [illegible] *on the stitches*. Even in an adult, in whom the periosteum of the palatine vault is tough and resisting, the cutting of the palate muscles is one of the essential steps necessary to facilitate the approximation of the pared edges of the loosened tissues surrounding an acquired opening, or defect of the palatine vault, as the result of scrofula, syphilis, or gunshot wound. The limits of this article will not permit of a more elaborate explanation.

In regards to gags I shall digress a moment to say that in a work on operative surgery, by L. A. Stimson, M.D., my gag is represented as T. Smith's gag. As Smith's gag may under some circumstances, as when the front teeth are defective or absent, be preferably used to mine, I here give a representation of it, and more especially that mine may not be mistaken for Smith's,

which, indeed, it does not resemble in the least. Fig. 4 shows a kaolatype of Smith's gag. For general purposes, however, I much prefer my own gag.



In this last case, as in all I have operated on, the muscles were thoroughly divided, the side-cuts made, but not so far back as shown in the figure, the periosteum partially detached, the edges carefully pared, and sutures

Fig. 4.—T. Smith's Gag.

passed and twisted up as represented in Fig. 5, which I have had copied, one-half size, from my report on "Cleft Palate," read before the American Medical Association of 1869.

I confidently anticipate a reproduction of bone in the newly formed palatine vault of this little boy, as I have heretofore obtained in young subjects. Indeed it may not be amiss if I refer to the cases of Miss S——, aged fifteen, and of Maria D——, aged seven, cited in the above-mentioned report, and in which cases the evidence of new bone, as attested by Dr. Charles K. Briddon, of New York, and myself, was strikingly manifest. It is astonishing to me the incredulity and opposition with which this operation has met, from the time I presented my first successful case up to the last one, only the other day. The parents of the little boy, Harry Ashton, were told by a Denver physician that the operation was unsuitable before the fourteenth year, and that he ran a danger of his life, etc. Dr. Dougan, however, urged the mother to have me do the operation, and kindly aided me in its performance. If the readers of THE RECORD will refer to the January number of *The American Journal of the Medical Sciences* for 1872, they will see that of two cases reported at that time the first was of a little boy, not quite three years of age, sent to me by the late Professor Charles A. Budd, of New York, and that he bore the operation well, and reacted better than any of my older cases.

It is but justice to myself to say that in nearly all of my cases the success has been complete, as regards union of the parts the entire length of the previously fissured palate, and that in every case the speech has been improved. But I, as others, have been particularly struck with the tightness occasionally of the newly formed palate, and which permits of more or less nasal tone, while, however, rendering the articulation more distinct, which distinct articulation is of the greatest advantage. By referring to the July number of *The American Journal of the Medical Sciences* of 1871, there will be observed the report of the case of an adult, J. C——, aged thirty-five years, the exact dimensions of whose palate, on account of its size, I here show, preferably to others. (See Fig. 6.)

Fig. 6.

I closed this extensive cleft, and on the fourteenth day removed the sutures, the union being complete and firm throughout the entire length of the previous cleft. The late Dr. James L. Little, and Dr. Nathan Bozeman, of New York, with others, were present at this operation. I also cite this case because it was an adult of thirty-five years of age, in marked contrast as to age and the lessened chances as to improvement in speech, to the little boy of less than three years of age. This adult patient, to quote from the journal above cited, was shown to about forty medical gentlemen at the New York Medical Library and Journal Association rooms, and called forth considerable comment about his speech, which was generally admitted to be quite satisfactory, and was an improvement on what it was before. "He was requested to read aloud, to pronounce the letters of the alphabet, and to count. It was explained to the gentlemen present that an operation would be attempted to lengthen the palate." To quote this case briefly, I should say that the operation to lengthen the palate, and which was a purely dissecting-room procedure of my device, proved a failure, and came near compromising seriously the good result that I had already obtained. However, there was, I thought, one or two letters pronounced with less nasal tone after this operation.

AN ARTIFICIAL HEEL BY GRAFTING. At a meeting of the Academy, M. Berger presented a patient in whom he was able to make an artificial heel by means of a large lump taken from the opposite leg. The graft succeeded completely, and the heel is now perfectly restored, but sensation has not yet appeared.

Clinical Department.

CONGENITAL MALFORMATION OF THE EXTERNAL EAR.

Dr. T. R. Williams, of Beechtree, Pa., writes [illegible]ds. T——, of this place, gave birth a few days ago to a female child who had a deformity of the left external ear. The cartilaginous portion was entirely wanting, and the soft parts were in a very rudimentary condition, except the tragus, or what I took to be it, which seemed to have about its usual development. The external auditory meatus was completely obliterated, not even a trace of any opening showing. Whether this condition obtains throughout the entire canal I cannot say, as I made no operation to ascertain this. The child weighed about nine pounds, and was otherwise perfectly developed. I would add that not long since I delivered a member of this same family of a child with hare-lip. I closed the fissure by an operation, using the hydrochlorate of cocaine successfully as a local anæsthetic."

PERITYPHILITIC ABSCESS — INCISION AND DRAINAGE—RECOVERY.

Dr. F. J. Adams, Assistant Surgeon United States Army, of Fort Assinaboine, Mont. Terr., reports the following case: A private, twenty-four years of age, after some premonitory symptoms of general malaise, was taken with cramps in the abdomen, accompanied with slight fever. He received morphine for the pain, but the fever continued, ranging from 100° in the morning to 103° in the evening. On the tenth day there was considerable tympanites, with tenderness in the right side of the abdomen from Poupart's ligament to the false ribs; there was some doughy swelling, but no distinct tumor, and no signs of fluctuation could be detected. During the next four days the difference between morning and evening temperature was on the average 3°, and the general symptoms indicated the formation of pus, though no fluctuation could be detected. On the evening of this day the needle of a hypodermatic syringe was inserted above the crest of the ilium, but no pus was found. The following morning an aspirator needle was thrust into the right side a little above the crest of the ilium and about two and one-half inches posterior to the anterior superior spine, downward and backward deep into the iliac fossa, and through it some very offensive pus was withdrawn. The patient was then etherized and an incision was made about an inch above, and parallel to, the crest of the ilium.

The muscles of this region were healthy in appearance but the transversalis fascia was somewhat thickened, and upon being freely incised there escaped at least one pint of thin ichorous pus of strong fecal odor. The cavity was explored with the finger, but no foreign body could be detected. After the cavity of the abscess had been thoroughly washed out with a solution of carbolic acid, a drainage-tube was inserted and the wound dressed with iodoform and oakum. The following morning the temperature had fallen from 102⅗° F. to 98° F. The cavity was each day washed out with a carbolized solution and the patient did fairly well until the seventh day, when the temperature rose to 101⅗° F., and although there was free discharge from the tube, the symptoms for four days following indicated the retention of pus. Accordingly, he was again etherized, the opening was enlarged, and upon exploration with the finger a pocket of pus was discovered extending farther down into the iliac fossa. Free exit was given and a rubber tube of one-half inch calibre inserted into the cavity for drainage. Each day a soft catheter was introduced through this tube and the abscess-cavity well washed with carbolized solution. The progress of the case from this time was good, and at the end of a month the wound had entirely healed.

Dr. Adams continues: "In the treatment of this case, it is now evident that the exploration with the aspirator needle should have been made as early as the tenth day instead of the fourteenth, or when the great difference between morning and evening temperature occurred, which, with other obscure constitutional symptoms, indicated the probable formation of pus. It was found that the largest size drainage-tube furnished by the Medical Department of the Army was much too small for the purpose of thorough drainage, and a stiff rubber tube, one-half inch calibre, was used, and proved to be entirely unirritating and was extremely effective, the improvement of the patient being constant from the time it was first inserted. I am of the opinion that had such a one been introduced from the first the necessity for a second operation would not have occurred."

SOME ADDITIONAL STATISTICS OF INTUBATION OF THE LARYNX.

Dr. F. E. Waxham, of Chicago, read a paper on "Intubation of the Larynx as a Substitute for Tracheotomy in the Treatment of Diphtheritic Laryngitis, with a Report of 83 Cases," at a meeting of the Chicago Medical Society on June 21st. The author referred to the various modifications that had been made in the instruments during the past year. First, the enlargement of the heads of the tubes to prevent slipping into the trachea; second, the addition of a shoulder to prevent their expulsion; and third, the construction of the tubes with thinner walls, giving greater breathing space and a better opportunity for the expulsion of false membrane. After exhibiting a feeding-bottle and trachea-forceps, the author presented statistics of 306 cases of tracheotomy performed in Chicago, with 58 recoveries, or 18.95 per cent. In 138 cases the ages were given; the average being five years and one month. In contrast to these statistics he gave the result of 83 cases of intubation performed in Chicago, with 23 recoveries, or 27.71 per cent.; the average age being three years and seven months. Eleven cases with 3 recoveries were under two years of age, one being an infant of fourteen months, another of eighteen months, and the other twenty months. Twenty-eight cases with 8 recoveries were under three years; 14 cases with 3 recoveries between three and four years; 15 cases with 6 recoveries between four and five years; 9 cases with 4 recoveries between five and six years; and 10 cases with 2 recoveries between seven and eleven years. Many of these cases were young nursing infants, and many were referred to him because they were too young, or because the cases were too unfavorable to warrant tracheotomy.

A CURATIVE OF EPITHELIOMA.

Dr. D. Tod Gilliam, of Columbus, O., writes: "I desire to call attention to the use of salicylic acid and cocaine as a curative for epithelioma. It so happened, not long since, that I had a small epithelial growth to remove from the face, and resorted to a 20-grain solution of cocaine as a local anæsthetic. After the lapse of some minutes I was surprised to find the diseased parts not only exsanguined, as is usually the case after the use of cocaine, but extremely friable and crumbly. I saturated a good-sized pledget of absorbent cotton with the cocaine and reapplied it, leaving it on for about thirty minutes. At the expiration of that time the diseased mass fell away with the slightest touch of the curette, leaving a healthy-looking surface which has healed kindly. This, I dare say, was not an epithelioma in the sense of being malignant, but was undoubtedly epithelial in character, and has suggested to me the feasibility of using cocaine in the former class of cases. I was the more surprised at the change produced, inasmuch as the usual effect of cocaine is to produce a condensation of tissues, and the bloodless

condition may, for aught I know, depend largely on this condensation. But the fact remains and we cannot gainsay facts. I would suggest as a preliminary to the use of cocaine that the horny layer of epithelium on the surface be softened by the appication of salicylic acid, as we all know from experience that cocaine will not penetrate keratinic substance. In the absence of any case to demonstrate this treatment on, and as, unlike Bill Nye with the comet, I have not almost discovered one, I put this forward hoping that some one will give it a trial. I am not unmindful of the fact that Dr. Shrady and his *confrères* used cocaine in the case of General Grant, or that the drug has now for a long time been in daily use for similar cases, but possibly not of the strength, quantity, and for length of time here indicated."

RADICAL CURE OF HERNIA BY A BUBO.

Dr. F. B. Streeter, of Glens Falls, N. Y., reports the following case: "H——, aged thirty-five years, Irish-American, canal-boat captain by occupation, while loading his boat in the summer of 1882 sustained a severe strain which resulted in a direct inguinal hernia of the left side. It was easily reduced and retained by a truss. In the summer of 1883 he again consulted me, this time for a bubo on the same side. After a long period of extensive inflammation with suppuration, during which he was unable to wear a truss, he recovered from his bubo, and from his hernia as well. Up to the present time his hernia has not recurred, although he is engaged in the heaviest labor. A suitable case presenting itself, I propose to try the effect of vaccination, although I hardly expect to gain results equal to those obtained by the 'bubo' treatment."

A DEVICE INTENDED TO FACILITATE APPLICATION TO THE POSTERIOR NARES OR LARYNX.

Dr. Howard Smith, of the United States Army, writes: "In making applications to the posterior nares or larnyx with the hand-atomizer, a practical difficulty is the inability to control the velum, or tongue, or to use the mirror while both hands are employed in working the instrument. In order to free one hand, I employ a simple device which I have not seen mentioned. The rubber tubing of the atomizer is lengthened to about five feet, so that the bulk can lie on the floor under the foot of the operator, close to the patient's chair. The operator holds the bottle and directs the spray with one hand, employs the other with the palate-hook, tongue-depresser or mirror, while he presses the bulb firmly and rapidly with his foot, producing a finer and stronger spray than when the hand is used. The application of the same device to the various powder-blowers is equally advantageous."

Iodoform in Phthisis.—The administration of iodoform in phthisis and other diseases of the lungs is becoming the regular treatment of these affections. Two Italian professors have made it a special study, and the conclusions they have arrived at are very favorable to the employment of the agent. Professor Chiaramelli, during four years at the Hospital of the Incurables, tried iodoform on a large scale, and found that it lessened the fever, modified the expectoration in its chemical qualities, and thus hindered putrefaction. In cases of caseous pneumonia, the learned professor said he thought that, given at an early hour, it would have a happy influence on the disease. M. Verneuil, who has already used iodoform dissolved in ether, in injections for cold abscesses, has given it also in phthisis, at the dose of two grains twice a day, suspended in ether and enveloped in capsules. Dr. Huchard associates it with creosote (one grain of each).

Progress of Medical Science.

Treatment of Pruritus Ani.—M. Grellety recommends for the relief of simple, non-symptomatic pruritus ani, frequent sitz-baths, ano-perineal douches, or bathing of the parts several times a day with warm water containing boracic acid (one part per one hundred) in solution. During the night starch poultices may be applied, or an ointment, composed of one part of oxide of zinc to five parts of vaseline, may be used. If these means are ineffectual recourse must be had to tents, saturated first with belladonna ointment, and then with a five per cent. ointment of cocaine, introduced within the anus. The food should be simple and bland, and alcoholic beverages should be eschewed.—*Le Moniteur Thérapeutique*, June 7, 1886.

Potassium Nitrate in Acute Rheumatism.—Dr. Grinevitski writes in the *Russkaya Meditsina* of April 20, 1886, concerning a method of treatment of acute rheumatism which he has employed for more than twenty years, with great success. He gives two drachms of potassium nitrate every two hours in a tablespoonful of raspberry syrup. At the same time he applies, night and morning, an ointment composed of extract of aconite, one drachm; ointment of gray oxide of mercury, two drachms; oil of hyoscyamus, one ounce. He says that he was usually able to arrest the disease within one or two weeks, and when treatment was begun early enough he seldom saw the disease invade other articulations than the one originally attacked.

Treatment of Facial Neuralgia.—Dr. de Coninck recommends the application of a one per cent. solution of cocaine hydrochlorate to the deeper portion of the external auditory canal, by means of a camel's-hair pencil, or a dropper. It is not necessary to use a solution of greater strength than this. The writer affirms that the pain, however intense it may be, will disappear at once, and should it return, it may be again relieved by the same means.—*Le Moniteur Thérapeutique*, June 7, 1886.

Hereditary Malformations of the Hands and Feet.—Some curious cases of malformations of the hands and feet, transmitted through several generations, have recently been reported in the *British Medical Journal*. The first series was reported by Mr. Henry A. Fotherby, in the number for May 22, 1886. The patient, J. A——, had a deformity of the hands and feet. In the upper extremity the apparent abnormalities began below the carpus, where only four metacarpal bones could be traced, the fourth and fifth bearing the little and ring fingers; the fingers were closely webbed together, though each had the normal number of phalanges; the missing metacarpal bone was, as far as could be determined, the third. Muscular movements were considerable and permitted of firm apposition of the webbed digits to the fleshy nodule covering the head of the first metacarpal bone. In the feet was found an abnormality, the exact similitude of which had existed in almost every deformed member of the family for five generations. The deviation from the normal seemed to begin immediately below the tarsus, where the metatarsus on each foot bifurcated to form two truncated, cone-like masses; the outer mass, which was the more slender and tapering, supported at its apex the little toe; the inner, and more solid, the great toe. It was impossible to estimate the number of metatarsal bones entering into each cone, as they appeared to be blended together, especially toward their distal extremities. In the internal lay a large ovoid gap. An almost exactly similar condition of things existed in the patient's married sister, whose child was also greatly deformed. The deformities had existed through five generations. Of the first and second generations, as far as known, one individual in each was deformed; of the

third generation there were two; of the fourth, to which the patient belonged, nine out of twelve [illegible] were deformed; of the fifth, children belonging to [illegible] in the fifth generation, six presented the peculiar malformations. In the same journal, under date of June 12, 1886, Mr. William Anderson relates another remarkable series, the deformities having been transmitted through four generations, affecting twenty-four out of thirty-six members of the family, and showing a tendency to increase in the later scions. The children of the undeformed subjects were all normally developed. The typical deformity was a pincer-like shape of the hands and feet. This predominated throughout the first three generations, except in the last member of the third, who had no thumb; and in the fourth generation the great toe also disappeared in two cases. The error of development was always limited to the digits and metacarpal bones, except in the fourth generation, where there were indications that some elements of the distal row of carpal or tarsal bones were imperfectly formed. The lesion was usually symmetrical. The morbid features were not confined to a mere suppression of parts. Syndactylism, compensatory hypertrophy, distortion of articulations, and multiplication of parts were also present. The manipulative power retained in the deformed parts was surprising, considering the degree and nature of the mutilation. The selection of the subjects for attack or exemption seemed to be quite capricious; neither sex nor order of seniority appeared to influence the manifestation; males and females were affected alike, and the defect was handed down as readily by the latter as the former.

The Prevention of General Tuberculosis by Removal of Local Affections.—In an article on this subject in the *Archives Générales de Médecine* for April and May, 1886, Dr. A. Marfon broaches the theory that tuberculosis belongs to that class of infectious diseases—among which are syphilis, scarlatina, etc.—in which one attack confers immunity against others, as a rule, and he therefore argues that all accessible local tubercular affections should be removed as speedily as possible. He has collected a number of observations of individuals, presenting evidences of cured tubercular adenitis, living for many years as nurses in hospitals, and surrounded by phthisical patients, who never betrayed any symptoms of subsequent tubercular infection. He has also examined a number of persons who had been cured of lupus, and never found any symptoms of pulmonary disease. He believes that scrofulous adenitis occurring in childhood confers immunity against tuberculosis, while a similar affection, first appearing in adult life, is usually accompanied by tubercular disease in the lungs. He says it is very rare to find patients suffering from pulmonary phthisis who have any marks upon them pointing to a previous adenitis or lupus, and he regards the latter affections as caused by an attenuated form of tuberculous virus. Auto-inoculation he regards as very exceptionable, and is consequently in favor of removal by operation, wherever practicable, of local forms of the disease.

Tremulous Paresis of the Heart.—There is no symptom more commonly found in the subjects of chronic alcoholism than tremors in certain muscles, more especially those of the extremities, and, less frequently, of the lips or tongue. There is at the same time a certain diminution, though not abolition, of power. It is well known that alcohol exercises an injurious influence upon the heart, causing at times myositis and fatty degeneration; but the following case, occurring in the service of M. Peter in l'Hôpital de la Charité (*Gazette des Hôpitaux*, June 12, 1886), is interesting as showing that the heart may also be the seat of functional disturbances, excited by this cause, characterized by weakened contractions and tremor. The patient, a man, aged thirty-five, had always been engaged in occupations requiring a considerable exercise of muscular force, and had also been addicted for a long time to the abuse of alcoholic liquors. He had had several attacks of gonorrhœa and gonorrhœal rheumatism. He was received into hospital suffering from delirium tremens. After recovering from this attack he was seen to have tremor of the hands, and on auscultation the heart-sounds were found to be weak, poorly accentuated, and flabby (*un peu flou*). A sphygmographic tracing showed a very short ascending line, indicating a weak heart, and the descending line was wavy and broken throughout its whole extent by a series of minute oscillations. The same characteristics were observed in tracings taken some days later, after complete recovery from the acute attack, showing that the tremor was a permanent condition and not to be regarded as a mere symptom accompanying the delirium tremens.

[illegible] reports a case of herpes zoster affecting the parts supplied by the terminal filaments of the median nerve in each hand. The eruption was accompanied by hyperidrosis of the same parts, trophic disturbances of the skin and nails of the fingers supplied by the median nerve, and by thumb clonus. The latter consisted in a trembling of the thumb, caused by sharp palmar flexion, which lasted ordinarily for fifteen to twenty seconds, but which ceased upon extension of the member. The zoster reappeared at intervals.—*Centralblatt für klinische* [illegible]. May 15, 1886.

The Connection between Scarlet Fever and Heart Disease.—Dr. Henry Ashby has made a study of 900 cases of scarlet fever which have been treated at the Children's Hospital, Manchester, during the past five years (*The Lancet*). The question is raised as to the part played by the virus of scarlet fever in exciting or predisposing to an attack of rheumatism. The commonest form of joint-affection which complicates scarlet fever in children is of a form of synovitis, but it is very rarely accompanied by endocarditis. These attacks differ in many ways from acute or subacute rheumatism—they are more fugitive in character, rarely recurring or returning to a joint when once it has left, and exhibiting an especial tendency to attack the synovial membranes on the backs and palms of the hands, finger-joints, soles of the feet, and cervical vertebræ. The attacks mostly take place from the seventh to the ninth day of the fever. Apart from synovitis, attacks undistinguishable from true rheumatism are liable to occur at the end of the third or during the fourth week, much at the same time as nephritis is liable to supervene. This post-scarlatinal rheumatism is commoner in young adults than in children, and in these attacks endocarditis is by no means uncommon. Cases recovering from rheumatic fever, and then attacked with scarlet fever, often suffer from a relapse of the rheumatism; but in what way the poison of scarlet fever determines the relapse in these cases the author cannot say definitely. Nephritis following scarlet fever is a not infrequent cause of cardiac lesions. A certain amount of dilatation of the left ventricle, with more or less compensatory hypertrophy, occurs in most cases of scarlatinal nephritis of any severity. Both endocarditis and pericarditis may take place, and occasionally embolism occurs. Occasionally pyæmia complicates scarlet fever, and then periendocarditis often accompanies the attack, which is generally fatal. No doubt in some cases of scarlet fever there is some dilatation of the heart, but this does not amount to anything of consequence unless there be nephritis as well. In acute nephritis, however, dilatation may take place very quickly, and yet no murmur is detected; and, even when a murmur has been found, the author says he has seen no evidence at the post-mortem examination of endocarditis. This dilatation may be perfectly recovered from, but many cases end fatally.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, August 7, 1886.

ICE-CREAM POISONING.

IN our issue of July 17th, when commenting upon the numerous cases of ice-cream poisoning reported this season, we referred to the fact that Professor Vaughan claimed to have discovered the *fons et origo* of the poisonous principle in a new "ptomaine" which he terms tyrotoxicon.

It will be remembered that samples of the noxious cream which played such sad havoc with the festal Michiganders were submitted to Professor Vaughan for analysis, and we now have in the report of the proceedings of the Michigan State Board of Health, July 13th, a detailed report upon "Tyrotoxicon—its Presence in Poisonous Ice-cream, its Development in Milk, and its Probable Relation to Cholera Infantum and Kindred Diseases."

We cannot too highly commend the energetic zeal displayed by Professor Vaughan in the execution of his task, and the promptitude of the secretary of the board in presenting to the profession the results of the investigation. Everything relating to the adulteration of food and food-poisons cannot fail to be of the highest possible interest and importance, both to the public, who are so nearly concerned, and to the profession, who stand in the relation of guardians of the public health.

We regret that the want of space forbids the publication of the entire report in our columns; we can give only a brief synopsis of its contents.

Professor Vaughan first alludes to the fact that about one year ago, after two years of close investigation, he succeeded in isolating from samples of cheese which had produced alarming symptoms in many persons a highly poisonous ptomaine, to which the name tyrotoxicon (cheese-poison) was given.

He then made numerous analyses of milk with the view of detecting the same poison. These tests were followed by negative results until the milk had been kept from three to six months; he then succeeded in getting the poison from one of the bottles. Ten drops of an aqueous solution of this poison placed in the mouth of a dog three weeks old caused, within a few minutes, frothing of the mouth, retching, and vomiting of a frothy fluid, and, after some hours, watery stools.

The facts of the Michigan ice-cream poisoning, as gathered from the testimony presented in the report, are briefly these: Eighteen persons were seriously affected by eating the cream. "The milk of which the cream was made was fresh and sweet morning's milk, with the cream of the milk of the night before from the same cows. The milk was kept in a cool, clean milk-cellar. The custard was made about noon that day, and immediately afterward the process of freezing was begun. The vessels were all thoroughly clean. There was no possibility of anything adhering to them, for they were scalded, wiped, and dried before being used. The only ingredients used were the milk, cream, eggs, best granulated sugar, and the flavoring. The lemon-cream was frozen first, then taken out and packed solid with ice and salt. The vanilla-cream was frozen in the same manner. The best Jennings extract, about the usual quantity, was employed, but not in excess. The cream was eaten in the evening by many people in the village. All of those who ate of the vanilla-cream were made sick, and none of those who ate of the lemon-cream suffered any inconvenience. The milk was the same in both, milked from the same cows the same morning that the cream was made, so that there was no difference in the custard used in making the vanilla-cream and the lemon-cream; but it turned out the one made people sick and the other did not."

The symptoms of poisoning in these cases are thus graphically described by Dr. Moffitt, one of the sufferers:

"About two hours after eating the cream everyone was taken with severe vomiting, and after from one to six hours later with purging. The vomit was of a soapy character, and the stools watery and frothy. There was some griping of the stomach and abdomen, with severe occipital headache, excruciating backache and 'bone pains all over, especially marked in the extremities. The vomiting lasted from two to three hours, then gradually subsided, and everybody felt stretchy and yawned in spite of all resistance. The throats of all were œdematous. One or two were stupefied; others were cold and experienced some muscular spasms. A numb feeling, with dizziness and momentary loss of consciousness, was complained of by some. Temperature was normal, and pulse from 90 to 120. Tongue dry and chapped. All were thirsty after the vomiting subsided, and called for cold water, which was allowed in small quantities with no bad results. After getting out no one of the victims was able to be in the hot sun for several days, and even yet (about ten days after the poisoning) the heat affects myself. I attended twelve persons, besides being sick myself, and all were affected in pretty much the same way. Several complain yet of inability to retain food on the stomach without distressing them. The man who made the cream took a teaspoonful of it, and he vomited the same as those who ate a whole dish, but not so often nor for so long a time. All are affected with an irresistible desire to sleep, which can scarcely be overcome."

The poisoning occurred on June 9th, and four days later, June 13th, Professor Vaughan received a sample for analysis. An aqueous solution of the filtrate was given to a kitten, and produced retching, vomiting, and watery stools. Other experiments were made later, with the production of a similar train of symptoms. Professor Vaughan is of the opinion that the poison is not connected in any way with the ordinary decomposition of milk. He regards it as a chemical body produced by

fermentation. He has not, as yet, been able to obtain the poison in quantities sufficient to enable him to make an ultimate analysis of it.

While Professor Vaughan deserves credit for the industry and painstaking care with which he conducted his investigations, further proof is needed before his theory of the causation of ice-cream poisoning can be accepted as final.

It is a matter of regret that his toxic substance is so indefinite a compound; he does not acquaint us with its physical properties, its chemical formula, or the reagents by which it may be recognized. His theory of its development in that portion of the ice-cream flavored by vanilla seems somewhat improbable. He says: "While the lemon-cream was being frozen, that part of the custard which was to be made into vanilla-cream continued to ferment, and before the freezing process was begun enough of the poison was generated to seriously affect those eating of it."

Since the freezing of cream is usually accomplished in from fifteen to thirty minutes, it seems hardly conceivable that fermentation should advance at such a rapid rate as to convert what a few moments before was an innocuous fluid into a highly poisonous compound.

Again, his theory does not explain the occurrence of poisoning, with the production of identical symptoms, from the use of other alimentary preparations, as pastries, puddings, etc., in which only a minimum quantity of milk is used.

In concluding his report, Professor Vaughan calls attention to the probable relation of tyrotoxicon to cholera infantum and kindred diseases. From the similarity of the symptoms of ice-cream poisoning to those of summer complaints, he argues identity of cause. While this may be important, if true, yet we think much harm may be done by the implied influence of the possible danger of feeding infants with milk. No doubt this will be seized upon by the venders of artificial foods for infants and utilized as a boom for their business.

DIPHTHERIA AND CROUP.

ALTHOUGH the mind of the profession is still divided as to the question of the identity of diphtheritic and true croup, whether we have to deal with one or with two distinct diseases, the majority of the most recent writers on the subject would seem, following Bretonneau, to incline to the belief that there is no practical difference between the affections described under these two names.

The author of the articles on "Croup" and "Diphtheria," in Quain's "Dictionary of Medicine," the late Sir John Rose Cormack, says that "membranous exudation is never a result of simple acute inflammation, or, in other words, there is no such disease as the croup of Home, Cheyne, West, and Sansom." Dr. Thomas J. Walker, in the article on "Diseases of the Larynx" in the same work, takes the same ground, and speaks of "that form of inflammation which is characterized by the formation of a false membrane in the larynx, namely, croup or laryngeal diphtheria." The writer of the article on "Diphtheria," in Wood's "Reference Handbook," Dr. Harold C. Ernst, says that "the question of the identity of the two processes, croup and diphtheria, from a pathological standpoint, may be considered to be settled in the affirmative, so far as to justify the assertion that true croup—membranous laryngitis—is one form of diphtheria." Dr. A. Jacobi, although the author of two separate articles on "Pseudo-membranous Laryngitis" and on "Diphtheria," in Pepper's "System of Medicine," makes no clear distinction between the two affections, and seems to regard membranous laryngitis as but one variety of diphtheria. In describing the former disease, he says that "as a rule the membrane makes its appearance in the pharynx first, from there to descend into the larynx. In other cases, the membrane is found in the bronchi and trachea first, and invades the larynx from below." Professor Steiner, also, in the article on "Croup," in "Ziemssen's Cyclopædia," writes that "the attempt to distinguish croup and diphtheria as two entirely distinct diseases has been unsuccessful, both from an anatomical and a clinical standpoint," and he himself evidently regards the two processes as identical. Dr. Morell Mackenzie argues strongly against the duality theory, and, in his monograph on "Diseases of the Larynx, Pharynx, and Trachea," writes: "Most physicians in this country [England] who have had the opportunity of studying the disease in the wards and in the dead-house now regard croup as a form of diphtheria. At an early period Dr. George Johnson maintained the identity of croup and diphtheria; and later, our great clinical teacher, Sir William Jenner, gave in his adhesion to this doctrine. The renowned Traube, of Germany, had previously accepted the unity theory."

On the other hand, the non-identity of diphtheritic and pseudo-membranous laryngitis has been affirmed by many authorities. Dr. George W. Gay, the author of the article on "Croup" in "The Reference Handbook," affirms his belief in the existence of two distinct forms of the affection, one of which is "an acute, non-contagious and non-infectious disease of the larynx, local in its nature, confined to the upper air-passages, not epidemic, characterized by the formation of false membrane," while the other "is an acute, contagious, infectious, and often epidemic affection, presenting a membranous deposit in the fauces, larynx, and other localities, accompanied by symptoms of blood-poisoning." He states, however, that the first form, primary croup, is at the present time of comparatively rare occurrence. Mr. William Squire, the author of the articles on "Croup" and "Diphtheria" in Reynolds' "System of Medicine," is also a firm advocate of the duality theory, and this opinion is shared in by Fordyce Barker, Austin Flint, Niemeyer, J. Lewis Smith, and others.

The arguments of the dualists have been again very clearly and forcibly stated by Dr. J. M. Clemens, of Louisville, in a paper read before the Medico-Chirurgical Society of that city, and published in the first number of *Progress* for July, 1886. The author seems to think that what he regards as the error of the upholders of the unity theory is to be explained by the fact that they wholly ignore the existence of a non-specific, non-contagious, idiopathic membranous croup, and he maintains that such a disease does certainly exist, and that it is perfectly distinct, and distinguishable from diphtheritic laryngitis. In support of his view he enumerates the points of dif-

ference between the two affections, which we reproduce in parallel columns for facility of comparison.

A prodromal stage of two or more days without hoarseness or cough; more or less profound constitutional disturbance; elevated temperature, which often subsides after the first onset of the disease, sometimes becoming subnormal, to rise again with the invasion of the larynx and trachea.	A sudden onset, or following within a few hours on exposure to cold and wet; little or no constitutional disturbance; elevated temperature, continuing till amendment is established.
Mottled or irregularly reddened fauces, often more conspicuous on one side than the other.	Uniformly pale-red or bright-red—never mottled—appearance of the fauces, which are conspicuously free from loose secretion.
Enlarged and painful lymphatic glands, particularly the submaxillary at the angle of the jaws.	There is never enlargement of the submaxillary lymphatics.
Exudation on the tonsils in the fauces, sometimes in the nares, on the lips, etc.	There is no exudation on the tonsils in the nares or fauces, except, possibly, in rare instances the intense inflammatory action having extended by sympathy of continuity to the territory immediately contiguous to the entrance to the glottis; by strongly depressing the tongue the upper border of the membrane may be seen.
Early appearance of albumen in the urine as a rule.	Albumen is never found in the urine.
A fetid breath of a sweetish, musty odor, similar to that in scarlatina.	The peculiarly fetid breath is never present.

In addition to the signs above enumerated the author adds that diphtheritic croup is a general disease of markedly asthenic character, while true, or pseudo-membranous croup, is a local affection of sthenic type.

The importance of this question is most certainly one which can hardly be overestimated. For it has a bearing not only on the therapeutic management but upon the prognosis and the prophylaxis as well. But, while in the abstract an error is always wrong and to be avoided if possible, yet, unless the physician can persuade himself absolutely that he has to do only with a local, non-contagious, membranous laryngitis, he would do well, in the present state of our knowledge, to regard every case of membranous croup as diphtheritic in character, and to take his precautions accordingly. If err we must, it is better to err on the safer side.

THE PENDJEH ULCER.

At the time of the threatened difficulties between Russia and England, in Afghanistan, the Russian troops, who had been massed in great numbers on the borders of that country, suffered from a peculiar affection resembling, and which probably was one of the varieties of, what is known under the various names of Aleppo evil, Delhi boil, Biskra button, etc. Dr. N. Suski, of the Russian army, observed a number of cases of the disease among the members of a Cossack regiment stationed at Merv, and reports them in *Vratch* of February 27, 1886.

The affection, he says, may be described as passing through three stages. It appears as a small red spot, which gradually increases in size and becomes raised in the centre. It is at first indurated, but soon breaks down and forms a rounded ulcer with irregular borders and sloughing base. In the second stage the ulcer increases in size, and others form in the neighborhood, and soon unite with the primary sore. The suppuration is profuse. At this time the cutaneous lymphatic vessels become irregularly enlarged, giving rise to little kernels beneath the healthy skin at a distance from the ulcer. The larger lymphatic glands do not, however, become implicated. The third period is that of cicatrization. After a variable period the ulcer assumes a healthy aspect, granulations form, and healing occurs under a scab. The cicatrix so formed has a rough, uneven appearance, somewhat similar to that following a burn. The ulcers may appear on any portion of the body, but seem to select by preference the face, neck, abdomen, wrists, and ankles. When occurring on other parts they arise usually from auto-inoculation.

Dr. Heidenreich, also of the Russian army, who made a careful study of the disease, is said to have found a special microbe, which he regarded as the causative agent. The results of treatment would seem also to support this idea, as it was found that sublimate solutions were most effectual in shortening the course and preventing the spread of the ulcerative process. The report of these investigations has not yet been published, but when it is, it will doubtless prove to be an important addition to our knowledge concerning the oriental sore, or Aleppo evil, the nature of which seems at present to be so obscure.

SLEEPING WITH THE HEAD LOW.

Few persons, we suppose, sleep without a pillow or a rest of some sort to elevate the head a little above the level of the body, and very few, if any, would think of habitually going to rest with the feet raised higher than the head. Yet if we are to believe the writer of an article in Pflüger's *Archiv*, Nos. 7 and 8, 1886, the latter is the only rational and proper position during sleep. Dr. Meuli-Hilty is the advocate of this plan. He was engaged in studying the physiological effects of such a reversal of the normal position of the body, and found, among other results, that the circumference of the neck was increased nearly two inches, by reason, chiefly, of a swelling of the thyroid gland. He frequently fell asleep while in this position and occupied in his studies, and found that he always awoke earlier in the morning, felt greatly refreshed, and was capable of much better work during the day than after a night's rest taken in the usual way. He has now slept with his feet higher than his head for the past four years, and his experience leads him to commend the method most highly. He says in this way the brain receives a more plentiful blood-supply and is consequently better nourished, while there is no danger of so much blood passing to the cerebral structures as to cause congestion. This danger is obviated by the enlargement of the thyroid gland, which holds back a certain portion of the blood in its dilated vessels, and which also acts as a regulator of the cerebral circulation by exerting pressure upon the carotids, and thus diminishing their calibre. Another advantage which Dr. Meuli-Hilty claims for his method is that it is prophylactic against pulmonary phthisis. The apices of the lungs

being dependent, receive a more plentiful blood-supply, and are thus rendered stronger, and less liable to become the point of origin of tubercular disease. The writer's assertions may be correct, and his method may, as he claims, be the only rational one, but it is likely to be a long time before he can induce mankind to regard pillows as a useless and harmful part of the bed furniture.

News of the Week.

Ataxic Paraplegia has been given by Charcot as a form of chronic myelitis in which the lateral and posterior columns of the cord are both involved. The disease is characterized by ataxia and spastic paraplegia, and as the spastic symptoms often predominate, the name above given is not a very good one, and does not deserve adoption.

Lunacy in England.—The report of the Commissioners of Lunacy for 1885 shows that there are now 80,156 lunatics in Great Britain and Ireland, being a ratio to the population of 1 to 349. In the last year the number of lunatics has relatively decreased.

In Acute Suppuration the most important etiological factor, according to Dr. D. O. Krantsfield, is the presence of two forms of micro-organism—staphylococcus pyogenes and streptococcus pyogenes. These always exist when there is acute suppuration, but they may exist without causing suppuration.

Dr. Breisky has succeeded Professor Späth, of Vienna, who has retired from the chair of obstetrics.

A Public Disinfection Institute has been opened in Berlin under governmental direction. There are chambers capable of completely disinfecting the clothes of two hundred families daily. All conceivable apparatus for thorough disinfection are provided. Such an institution would find large opportunities for usefulness in this city.

Antipyrin as a Hæmostatic, in five per cent. solution, is said by Casati to be an efficient hæmostatic. It may be used both internally and externally.

In Defence of Homœopathy.—A London paper states that it is proposed to establish an association for the purpose of dispelling the ignorance that prevails regarding the homœopathic system. The title of the new organization will be the Homœopathic League, and its objects are, in the words of the prospectus, first, "to give a popular explanation of homœopathy, and to show that it is founded on reason, science, and experience; second, to defend homœopathy from the misrepresentations of its opponents, and to obtain fair treatment for it.

To Select a Site for a New Insane Asylum in Northern New York.—A commission—consisting of Hon. William P. Letchworth, Chairman, Buffalo; James Spencer, Esq., Secretary, Whitehall; Hon. C. C. B. Walker, Corning; Dr. Peter M. Wise, Willard; Dr. Joseph M. Cleaveland, Poughkeepsie—has been appointed by a recent act of the Legislature to locate an asylum for the insane in Northern New York, with "power to receive by gift or to contract for the purchase of such site for the location of said asylum, subject, however, to the approval of the next Legislature, to whom they shall report their action in the premises within ten days after the commencement of the session, together with plans and estimates for constructing buildings suitable to accommodate five hundred inmates. Such plans to admit of such further extension of the buildings as may be necessary to meet the future requirements of the State in providing for the insane." The commissioners present the following as essential points to be considered in the selection of a site for a hospital for the insane: A healthy locality; a tract of good land, embracing not less than five hundred to one thousand acres; easy access by railway, with facilities for side-track connections if desired; a bountiful and unlimited supply of pure, sweet water, the source, if practicable, to be sufficiently elevated to allow of distribution throughout the buildings by gravitation; the site should afford facilities for surface drainage, and for the easy and final disposal of sewage without danger of polluting waters that are used for drinking purposes; the ground about the buildings should be free from secret springs and submoisture. The commissioners purpose visiting the northern counties at an early day, due notice of which will be given beforehand. In the meantime, any inquiries, proposals, or communications in regard to sites may be addressed to James Spencer, Secretary, Whitehall, N. Y.

The Best Method of Measuring Albumen in urine, according to Dr. George Johnson, is by Esbach's tubes, as described in *The Lancet* of January 23, 1886. At present the tubes must be imported from London, or from MM. Brewer Frères, Paris.

The Poison-Ivy.—Dr. Fred. Sumner Smith, of West Hartford, Conn., says: "I wish to correct a statement in a recent issue of The Medical Record. You say, 'The poison-oak, or Rhus toxicodendron, is a rare plant, while the poison-ivy, or Rhus venenata, is comparatively common.' The poison-oak and poison-ivy are identical, and the botanical name is *Rhus toxicodendron*. The *Rhus venenata* is the poison-sumach, or dogwood. The poison-oak (or poison-ivy) is very common, while the poison-sumach is, fortunately, less common. I speak with confidence, from an abundant acquaintance, both personal and professional, with both of them." Dr. Edwin Barnes, of Pleasant Plains, N. Y., further says: "I cannot agree with the statement in a recent issue of The Medical Record, that there is no specific for rhus poisoning. Living as I do in a section of country where Rhus venenata and Rhus toxicodendron are very common, I have at least fifty cases a year, and have never known a case to last over five days when treated as follows. Internally I give the following: ℞. Sodæ sulphocarbolat., ℥ jss.; fl. ext. gelsem., ℥ j.; aquæ pur., ad f ℥ iv. M. Sig.: A teaspoonful every two hours. Locally, the patient bathes the eruption every two hours with a nearly saturated solution of hyposulphite of soda. This will cure any case of poisoning by Rhus venenata in three days; the Rhus toxicodendron is more virulent, but I have never, in twenty years, known it to last over five days when treated as above. The worst cases of rhus poisoning that I meet with are where, through care-

lessness, some sticks of Rhus toxicodendron get into the firewood and are burned, or where some one susceptible to the poison stands too near a brush-pile where Rhus toxicodendron is being burned. This susceptibility varies greatly. I have frequently chewed the leaves and bark of Rhus toxicodendron, have stripped the vines of Rhus venenata from the trees and fences, and yet members of my own family will be severely poisoned by simply standing too near to either of the poisonous woods."

Imprisoned for Malpractice.—A Berlin physician has been condemned to two months' imprisonment for malpractice. A woman had an abortion followed by menorrhagia. The physician chloroformed her, with the assistance of a midwife, scraped the uterus with a sharp spoon, and injected liq. ferri sesquichloride. The patient died of peritonitis, and on autopsy several holes in the uterus were found through which the injected fluid had passed into the abdominal cavity.

The So-called Revolution in the After-treatment of Cataract Extraction.—Dr. John B. Roberts, of Philadelphia, sends us the following: "I was interested a day or two ago in some remarks made in one of the current medical periodicals concerning the fear that French dentists have of the use of nitrous oxide as an anæsthetic. The irresistible conclusion was that the dental profession in that country did not know of, or did not heed, the teachings of the clinical experience of their American brothers. To-day I have in a similar way been forcibly struck by reading, in a recent issue of The Record, the notice of a revolution in the after-treatment of cataract extractions, which is called forth by my friend Dr. Chisolm, of Baltimore, having rejected the ordinary cotton and bandage for such cases. It is to me simply astonishing that none of those who heard the subject broached at the recent meeting of the American Medical Association were aware of the fact that here in Philadelphia a similar after-treatment has been adopted and earnestly advocated by Dr. R. J. Levis, for at least twelve years. I, of course, believe that they had forgotten or never heard of the fact As a pupil and assistant of Dr. Levis, at Wills Eye Hospital, Pennsylvania Hospital, and Jefferson Medical College, and in private practice, I know he has not used the cotton dressing since 1874. How long before that time he abandoned it I am unable to state. He simply stiffens the upper lid with two or three small superimposed semi-ellipses of rubber, adhesive plaster, or some similar tissue. Occasionally, though not often, he adds to this a narrow strip from the root of the nose to the malar bone. This dressing has been constantly taught by him to large clinical classes, and discussed years back, when he was connected with the Wills Eye Hospital, with the surgeons of that ophthalmic institution; but, so far as I know, no one follows his example here except Dr. H. Augustus Wilson, formerly eye-surgeon to St. Mary's Hospital, and myself. That it is far preferable to the cotton dressing I am fully convinced, and I never use any other after extraction of cataract or corneal operations. In a clinical lecture given by Dr. Levis in the winter of 1876–77, published in the *Medical and Surgical Reporter*, January 20, 1877, you will find this dressing accurately described. I send you a marked copy. It was described about the same time in the *New York Archives of Clinical Surgery*. As the article in the *Reporter* states, the case then subjected to operation was the five hundred and fourth done by Dr. Levis subsequent to the abandonment of the old flap operation; and, as he had previously recorded one hundred successive cases, with only two complete losses of vision, it may be presumed that his experience was sufficient to warrant his advocating a peculiar method of dressing. I am not able to say whether the hundred cases mentioned were all treated by the simple dressing. Many of his cases were formerly, and are still, treated in open wards, in which the patient is protected from light merely by a screen around the bed and closing of the shutters, or drawing down the curtain of the opposite window. In my little monograph on 'Surgical Delusions,' page 36, you will see 'the foolish practice of padding with cotton and tying up eyes that have been subjected to corneal operations and cataract extractions' described as a delusion needing frequent and loud-voiced condemnation. On page 179, 'Trans. Medical Society, State of Pennsylvania,' for 1884, the same topic is discussed. I call attention to these facts merely to show that new things are often older in principle than we think, and especially to emphasize and corroborate Dr. Chisolm's words, in the hope that the uncomfortable, irritating, and conjunctivitis-producing bandage may be discarded by every ophthalmic surgeon."

An Absurd Claim.—"Pittsburg is pre-eminently a homœopathic city, owing to the efforts of our distinguished Nashville friend, Dr. J. P. Dake, who, in 1856, treated three hundred cases of cholera without losing a single patient, while the 'old school' physicians were losing one half of theirs." So writes a correspondent of the *Physician's and Surgeon's Investigator*. But no one ever treated three hundred cases of genuine cholera without a death.

Compound Tincture of Capsicum.—A mixture which is compounded by M. Poulet has been much praised as a pain-killer. Its composition is: ℞. Tinct. capsici, 200.0; Liq. ammon, 100.5; Essentiæ thymi, Chloral hydrat, āā 10.5; Alcohol, sixty per cent., 1,000.0. M. The pepper, ammonia, and alcohol are digested together for a month, then chloral and thymol added. It is used externally as a liniment, either pure or diluted with oil; internally, in doses of ten to twenty drops. It is recommended for dysentery, enteritis, and rheumatism.

The Death of Dr. Moxon, of Guy's Hospital, London, is announced. He died suddenly of apoplexy or heart disease, on July 22d. The particulars have not yet reached us.

Cremation and the Catholic Church.—By a decree of the Roman Inquisition, dated May 19, 1886, and confirmed by the Pope, Catholics are forbidden to join cremation societies, or to order their own or the bodies of others to be cremated. His Holiness, in confirming the decree, condemns the "detestable abuse of cremating human bodies."

Professor Semmola, of Naples, has been raised to the dignity of Senator of Italy.

Thirteen Preventive Inoculations against Hydrophobia have been made in Vienna, by Dr. Chantemesse, assistant to Professor Albert.

The Daily Press and Medical Societies.—The Chicago Medical Society has a standing resolution under which reporters for the daily papers are excluded. The rule is practically inoperative, says *The Chicago Medical Examiner*, because the gist of the meetings get out when anything of note or interest to the public occurs. A motion to rescind the resolution, however, recently failed.

New Local Anæsthetic.—Dr. May claims that five to ten per cent. solution of brucine is an efficient local anæsthetic, especially useful in relieving pruritus. The same author has shown that hypodermatic injections of one to two or three grains of a solution of theine relieves the pains of neuralgia.

"Rectal Expression."—It has not been generally supposed that the rectum possesses any particular expression. If it had, we should say, in consideration of the average state of its contents, that it ought to make a very wry face. We learn from our exchanges, however, that the term "rectal expression," which has been widely used of late, refers to the process of insinuating two fingers into the rectum during the second stage of labor and pressing out the head.

Reviews and Notices.

Pocket Medical Formulary. Alphabetically Therapeutically. By Alexander Hazard, M.D., and Bernard M. Goldberg, M.D., revised and enlarged by Abraham S. Gerhard, M.D. Philadelphia: Published by Collins, Printer. 1886.

"The busy and hard-worked practitioner," to whom the "Pocket Medical Formulary" is dedicated, is expected to tuck away in his pocket this little book, which resembles a diary, and to look through its alphabetical list for a prescription to fit the case of which he has made a diagnosis and has not in mind the treatment he wishes to give. It has blank pages for the insertion of new formulæ which it is desirable to make a note of. Such an affair has the appearance of a cook-book and does not seem exactly a scientific method of practising medicine; nevertheless it is not without its use and value if only to find the varied compounded prescriptions of different authorities relative to a disease brought together in this compact form.

A Manual of the Diseases of the Skin. By Balmanno Squire, M.B. Lond. Pp. 194. Chicago: A. N. Marquis & Co. 1886.

Epitome of Diseases of the Skin. By Louis A. Duhring, M.D. Pp. 130. Philadelphia: J. B. Lippincott Co. 1886.

Both of these volumes are condensations of the knowledge of skin diseases into a very small compass, in order to supply pocket text-books for students. Dr. Squires follows the classification of Williams, that is according to the elementary lesion, as macules, vesicles, etc., while Dr. Duhring follows that of Hebra and Rokitansky, which, he explains, is based upon the anatomy of the skin, the pathology of the lesions, and, to a slight extent, upon their etiology.

Dr. Squires' book is rather more extensive, as its title of "Manual" would imply, than Dr. Duhring's "Epitome." Both are characterized by terseness of expression as well as clearness, and are valuable for the purpose for which they have been published.

Investigation into some Morbid Conditions. By William Russell, M.D., M.R.C.P. Edinburgh: Bell & Bradfute. 1886.

Dr. Russell has included in this volume his thesis which he presented for the degree of Doctor of Medicine in Edinburgh, for which he received the gold medal of the University, and the Cartwright prize essay entitled "The Heart in Debility." The whole forms an interesting and valuable contribution to the literature on the subject, and will be read and referred to with profit.

The Year-Book of Treatment for 1887. Published by Lea Brothers & Co. 1886.

To review a "year-book" is about as difficult a task for a reviewer as it would be to review a dictionary; nevertheless the reading furnished by such a work is of a most interesting nature. Here within small compass is given the net result, the practical outcome of the myriad medical writings of a year. The physician will find it useful to refer to in the same manner as he would use a dictionary.

The Medical Annual. By Dr. J. E. Taylor, F.L.S., F.G.S. London: Henry Kimpton. 1886.

The "Medical Annual" is a record and review of the year's progress in medicine, surgery, and science, more especially in Great Britain. To boil down the medical literature of the world for a year to two hundred and twenty-five pages of an ordinary volume bespeaks patient industry on the part of the editor, and meaty reading for him who peruses the work. The year, we are told, has not been fruitful in scientific discovery. The establishment of theory by the record of facts has characterized the research.

Space forbids entering into detail, even if one had the courage to undertake to still further compress what has already been compressed to well-nigh the uttermost limit, but the reader can judge how interesting a book must be which can give the latest scientific theory of how a Norwegian salmon can jump up waterfalls and the latest investigations of cerebral localization which will enable surgeons to trephine over the exact spot where the morbid process is situated in the brain.

How to Care for the Insane. A Manual for Attendants in Insane Asylums. By William D. Granger, M.D. Pp. 96. New York: G. P. Putnam's Sons. 1886.

Dr. Granger has written a clear, concise statement of the care of the insane, well calculated to inspire attendants to look properly after the condition, symptoms, and welfare of those under their charge.

The first three chapters of his book, entitled respectively "The Nervous System and Some of its Important Functions," "The Mind and Some of its Faculties," and "Insanity," illustrate the difficulty which one would encounter in preparing such strong meat to make it suitable pabulum for babes. A sentence or two will illustrate our meaning. "Many nerves are given off from the brain and cord and go practically everywhere." . . . "These nerves are white cords of different sizes. The one that goes to the leg, called the sciatic, is as large as the little finger." . . . "Our brains are very busy," etc. . . . "In common language we speak of the mind diseased. This is not strictly true, as it is the brain that is diseased, and, in consequence, we get disturbed mental action."

It is not until the doctor comes to giving practical directions, such as how to receive a patient, give him a bath, feed him, and make his bed, that he floats in smooth waters and becomes truly happy.

MANUAL OF DIFFERENTIAL MEDICAL DIAGNOSIS. By CONDICT W. CUTLER, M.D. New York: Published by G. P. Putnam's Sons. 1886.

LISTS of symptoms of the diseases which flesh is heir to, contrasted with each other, form at once the dryest and most interesting reading, if such a paradoxical statement is permissible, which can fall to the lot of a medical reader; but to the medical student who wishes to become conversant, and be prepared to pass the tribunal of an examination with them, these lists must be terrific. We cannot think that the student can compass the matter properly except by making his own tabulations; he will, however, find it greatly to his profit to study those of Dr. Cutler, which might serve him as a key to correct his own by, since they are models of thoroughness.

A MANUAL OF SURGERY. In Treatises by Various Authors. In 3 vols. Edited by FREDERICK TREVES, F.R.C.S., Surgeon to, and Lecturer on Anatomy at, London Hospital, etc. 12mo. Philadelphia: Lea Brothers & Co.

THESE compactly arranged volumes are intended to give a concise view of the principles and practice of modern surgery, and are composed of short, well-written articles by a large number of leading surgeons of Great Britain. The various subjects are handled with rare judgment, and present the essential facts of clinical practice in a nutshell. It is a successful compromise between the epitome and the more elaborate treatise, and will doubtless serve its purpose in enabling the general practitioner and surgeon in recognizing the leading landmarks of the science. The number of authors is large, and the assignments, judging from the results, have been very judicious. The different volumes are divided into the following subjects, respectively: Vol. I., General Surgical Affections, the Blood-vessels, Nerves, and Skin; Vol. II., The Organs of Locomotion and Special Sense, the Respiratory Passages, Head, and Spine; Vol. III., The Thorax, Organs of Digestion, and Genito-urinary Organs. The editor is a gentleman who has an enviable reputation as a clinical teacher and writer, which in itself is a guarantee of the excellence of his own articles and of those of his co-laborers.

A TREATISE ON DISEASES OF THE NERVOUS SYSTEM. By WILLIAM A. HAMMOND, M.D., Surgeon-General United States Army (retired list), Professor Diseases of the Mind and Nervous System New York Post-Graduate Medical School and Hospital, etc. Eighth edition, 8vo, pp. 945. New York: D. Appleton & Co. 1886.

THE eighth edition of this work speaks for itself in the fact of its existence. The talented author has carefully revised the previous editions, elaborating many portions which subsequent experience and observation have made necessary. A section has also been added on certain obscure diseases of the nervous system, comprising Tetany, Thomsen's Disease, Miryachit, and kindred affections. These subjects are treated, like others in the work, with a master-hand and with the pen of a ready and entertaining writer. The author made his reputation long ago, and that he is able to maintain it his last effort will abundantly prove.

DICTIONARY OF PRACTICAL SURGERY. By Various Hospital Surgeons. Edited by CHRISTOPHER HEATH, F.R.C.S., Holme Professor of Clinical Surgery in University College, London, etc. In two vols. 8vo, pp. 1,854. Philadelphia: J. B. Lippincott Co. 1886.

AS its title indicates, this is essentially a surgical dictionary. It follows out the traditional plan. The subjects are selected with a view to their importance, are arranged alphabetically with such elaboration of practical parts as is in keeping with the limits and scope of such a work. Each of the various authors is duly credited at the end of his article. As a rule the descriptions are short and very judiciously condensed, and when necessary cross references are made. All the subjects are well worked up, and are abreast of the advanced thought of the day. They are treated of, as far as practicable, in the following order: Cause, pathology, symptoms and diagnosis, treatment and prognosis. As a whole the work fulfils its mission, and will be duly appreciated by the working practitioner who wishes to add new volumes to his reference series.

BRIGHT'S DISEASE AND ALLIED AFFECTIONS OF THE KIDNEYS. By CHARLES W. PURDY, M.D., Queen's University, Professor of Genito-Urinary and Renal Diseases in the Chicago Polyclinic, etc. 8vo., 288 pages, with 18 illustrations. Philadelphia: Lea Brothers & Co. 1886.

DR. PURDY has written a book which will reflect a fair degree of credit upon himself. His views are well-expressed, and are quite generally accepted by those who have reached the enviable position of authorities in this class of diseases. The illustrations can be duplicated without special difficulty by examining kidneys the seat of acute and chronic changes, as they are met with at the post-mortem table of any large hospital. We regard this as no small degree of praise; for the larger percentage of illustrations of these lesions are of a very inferior order. As a matter of uniformity the author has, in common with most writers, mixed classifications and synonyms somewhat, but, it may be said, not to the special detriment of the original design of the book. One term, however, has been introduced which is fairly open to criticism. "Cyanotic Induration of the Kidney," is the name given to the condition more commonly known as "the kidney of heart disease," or "chronic congestion," or "passive hyperæmia of the kidney." The author's description of the kidneys that belong to this group is sufficiently clear, and includes many of the points which have been already described; but we had not heretofore been made aware that the condition exhibited a blue color. "It is, in fact, a condition of passive or venous congestion of the kidneys," is the language of the author, and the title of his chapter would be materially improved by making it include the idea thus expressed, rather than the condition of cyanosis. The book is divided into nine chapters: 1, Albuminuria; 2, Uræmia; 3, Acute Nephritis; 4, Chronic Nephritis; 5, Cirrhosis of the Kidney; 6, Scarlatinal Nephritis; 7, Puerperal Nephritis; 8, Lardaceous Degeneration of the Kidneys; 9, Cyanotic Induration of the Kidney. It is printed with large type upon heavy paper, and has a bibliography and an index. Dr. Purdy's well-written papers on testing the urine for albumen have already made for him a good impression, which will not be erased by the present volume, that contains so many practical points concisely expressed.

THE INTERNATIONAL MEDICAL CONGRESS.—The Vienna correspondent of the *Weekly Medical Review* writes: "At Hamburg, at Leipzig, and here, I have interviewed quite a number of the principal men in the profession, as to their intention to visit Washington and attend the World's Medical Congress next year. Gentlemen of the American Medical Association, who lately met at St. Louis, you thought you disinfected that wound produced in your ranks by the discussion of the Code question. At least you put a plaster over it, bandaged it up, and all went away smiling; but let me tell you that I find here, by talking with the leading men, that your last operation has produced very little impression on the medical mind here. The general impression is that the leading minds in our profession are at loggerheads, and that sufficient harmony cannot be attained to make the Congress a success. Then, again, you have no idea of the repugnance that many of these men have to a long sea-voyage."

Reports of Societies.

THE AMERICAN OPHTHALMOLOGICAL SOCIETY.

Twenty-second Annual Meeting; held at the Hotel Allyn, New London, Conn., July 21 and 22, 1886.

WEDNESDAY, JULY 21st—FIRST DAY—MORNING SESSION.

THE meeting was called to order by the President, DR. WILLIAM F. NORRIS, of Philadelphia.

DR. Peters, of New York; DR. Hubbel, of Buffalo, DR. E. Fridenberg, of New York; and Dr. Cutter, of New York, were invited to take part in the proceedings of the Society.

DR. H. KNAPP, of New York, read a paper entitled

PYOGENIC MICRO-ORGANISMS, WITH DEMONSTRATIONS AND EXPERIMENTS.

Dr. H. Knapp made some general remarks with reference to the dependence of suppuration on certain kinds of micro-organisms—the pyogenic bacteria. He exhibited these bacteria in numerous test-tube specimens on agar-agar and also under the microscope. He showed two rabbits which he had operated on the day before, for cataract, in the presence of members of the Society. Extraction had been made on the left eyes with clean instruments, and on the right eyes with instruments contaminated with staphylococcus pyogenes aureus. The left eyes were free from secretion. The wound of one eye was in a doubtful, the other in a good condition; whereas the right eyes discharged matter profusely, and were in a state of intense destructive inflammation. He then operated on two other rabbits in the same way. The four rabbits were examined the next day. The right eyes in all were suppurating, the wounds of the left eyes in three of the rabbits were in good condition. In one of the first two rabbits it was suppurating. This eye had become infected from the right eye of the other rabbit. They had been kept in the same box, and the operator had found them with their heads in contact.

In reply to a question as to the best method of cleaning instruments, Dr. Knapp said that the use of antiseptic solutions had the disadvantage of dulling the edge of cutting instruments. His experiments had shown him that simple washing with water in the case of smooth instruments, followed by friction with a clean towel, renders them bacteriologically clean. Where an instrument has a groove, or is at all rough, it is much more difficult to clean. Instruments like forceps may be put in the antiseptic solution. It must be remembered that in the majority of operations a certain quantity of infecting material is required to produce any effect. Where there is a free escape of liquid from the wound the material is washed off, but where there is a sucking-in process the danger is much greater.

DR. HUBBEL, of Buffalo, asked Dr. Knapp if there were not certain conditions of the eye which would favor infection of the wound after operation.

DR. H. KNAPP, in reply, said that a lachrymal discharge, with a certain amount of conjunctivitis, furnishes a favorable soil for the growth of bacteria. In operating in such cases, the discharge should be completely removed. A certain quantity of the pathogenic bacteria is required to produce infection. He had pricked the cornea and covered the wound with an emulsion of the bacteria. In only one out of every four or five did abscess develop.

DR. J. A. ANDREWS, of New York, said that mere contact of the microbe with the wound is not always sufficient to produce suppuration, especially in the case of the cornea, where the discharge is liable to be washed off. Where the material has been introduced into the wound and kept there for a short time he had never seen a failure.

In the cleaning of instruments he uses simply clean water, which has been boiled for some time.

DR. C. S. BULL, of New York, gave

AN ANALYSIS OF [illegible] RETINITIS [illegible] DISEASE.

He included only those cases which he had examined and followed to their termination. All cases due to scarlatina or pregnancy were excluded. Out of 500 cases examined only 108 fulfilled these conditions. The ophthalmoscopic examinations were made by the author, and the urine was always examined.

The prognosis with reference to the duration of life is very unfavorable. Of the 113 cases, 86 have died—57 during the first year and 12 during the second; 17 were still living, but 14 of these were seen within the last six months.

DR. E. GRUENING, of New York, remarked that none of his cases have lived over two years after the diagnosis of retinitis albuminurica had been made out. In this class of cases, he included only those in which the typical stellate changes were seen in the maculæ of both eyes.

DR. B. E. FRYER, of Kansas City, stated that albumen is occasionally absent from the urine for a short time in these cases. In two such cases he had found albuminose during the time that albumen was wanting.

DR. DAVID WEBSTER, of New York, was confident that in rare instances these patients do recover their general health and may live indefinitely. Some years ago he examined the eyes of a clergyman and found the typical appearances of retinitis Brightii. He had been examined fifteen years previously by a competent observer, who found the same condition, and also found albumen and casts in the urine. I had the urine examined and found a slight trace of albumen.

DR. O. F. WADSWORTH, of Boston, said that where the retinitis albuminurica comes on during or immediately after pregnancy, he had seen the stellate spots in the maculæ entirely disappear. He had also seen typical stellate deposits in cerebral tumor, and in what was supposed to be meningitis, but in which there was no albuminuria.

DR. GEORGE C. HARLAN, of Philadelphia, read a paper on

THROMBOSIS AND [illegible] OF THE RETINAL VESSELS.

The patient was first seen June 5, 1886. There had been no trouble with the eyes until May 7th, when she noticed dimness of vision in the left eye. This increased during the day, and the following morning there was only light perception in this eye. She was examined two weeks later by a surgeon who pronounced the condition one of embolism. There was no suspicion of specific disease. There was no uterine trouble, and the heart-sounds were normal. The urine had a specific gravity of 1.009, contained some albumen, but no tube-casts were found. Examination of the eyes showed no light-perception in the left eye. The media were clear. There were hemorrhages scattered through the retina. Some were striated, extending in long streaks along the vessels. With one exception all the vessels of the retina were converted into white bands. The exception was a small artery having an independent origin. The vessels were of nearly normal size. Five or six weeks later the hemorrhages had been absorbed, but there were no other changes. In July she had a slight attack of paralysis on the left side, and examination of the urine showed some albumen and hyaline tube-casts. The rapid onset and the occurrence of blindness within a few hours seemed to exclude the possibility of disease of the vessels. Embolism would not account for the condition. The speaker suggested that the partial blindness for the first few hours was due to hemorrhage, and that the complete blindness coming on later was due to thrombosis. Thrombosis

of a whole series of vessels is, however, rare. Another possible explanation is that there had been for some time disease progressing in the outer walls of the vessels without giving rise to sufficient disturbance of vision to attract attention.

Dr. William S. Dennett, of New York, called attention to

A NEW TEST-TYPE.

A card was presented which was designed for the use of educational institutions. It contained one set of letters, and a statement of the exact distance at which these letters should be seen. The desire was expressed that this or some similar card should be placed on the wall of every school-room, in a conspicuous place, so that it should become of necessity a familiar object and a standard of measurement that would be remembered through life.

Dr. H. Derby, of Boston, read a paper on

THE POSSIBLE RETARDATION OF RETINITIS PIGMENTOSA.

In America the disease is exceedingly infrequent, and is as a rule considered incurable. In 1881 a boy, three years of age, was brought to him from Western Virginia. It was observed that toward night vision diminished. There was no history of blindness in the family. Five years later he came again, accompanied by his sister, seven years of age. Both children were night-blind and presented the evidences of retinitis pigmentosa. Under the use of the constant current there was improvement. A similar case of improvement under the use of the constant current, under the care of Dr. Standish, was reported.

The object of the paper was to invite discussion as to the use or non-use of such eyes for educational purposes, and as to the possibility of adopting measures for delaying the progress of the organic change.

A third case, that of G. W——, aged fourteen years, was described. He presented the typical appearances of retinitis pigmentosa. Non-use of the eyes and the application of the constant current was recommended. He was subsequently advised by others to use the eyes freely. In five years vision diminished from three-tenths to one-tenth. This rapid progress of the disease, it was thought, might have been aided by the use to which the eyes had been subjected.

Dr. William S. Little, of Philadelphia, had seen in one case of retinitis pigmentosa, occurring in a deaf-mute, decided improvement in vision under the use of the faradic current. The improvement continued.

Dr. L. Webster Fox, of Philadelphia, had employed the constant current with success. He had found that it was the negative pole that produces the good results, and that if there were no enlargement of the field after three applications, no improvement was to be expected.

Dr. George Strawbridge, of Philadelphia, remarked that he had tried the use of electricity in this affection thoroughly some ten years ago. He did not obtain benefit in a single instance. He recommended the occasional use of alteratives, as bichloride of mercury and iodide of potassium, looking on these cases as probably of syphilitic origin.

Dr. Samuel Theobald, of Baltimore, had seen temporary improvement from the use of phosphate of iron, quinia, and strychnia.

Dr. S. D. Risley, of Philadelphia, stated that by the hypodermatic use of strychnia he had secured improvement in the central sharpness of vision. As far as he knew, the benefit has never been permanent.

He related the case of a young man who consulted him with retinitis pigmentosa, with marked contraction of the field and asthenopia, principally due to hypermetropic astigmatism. To relieve the asthenopia a weak solution of eserine was ordered. Under its use vision decidedly improved.

Dr. O. F. Wadsworth, of Boston, referred to the case of a young man, twenty-four years of age, a divinity student, who was seen in 1873, presenting typical retinitis pigmentosa so far as the ophthalmoscopic appearances. He continued his work, and, eight years later, vision was about the same, but the visual field seemed to have decreased to a slight extent.

Dr. Edward Jackson, of Philadelphia, read a paper on

THE EQUIVALENCE OF CYLINDRICAL AND SPHERO CYLINDRICAL LENSES.

The committee to whom was referred the consideration of the proposition with reference to the organization of a congress of American physicians and surgeons reported the following resolutions, and recommended their adoption :

Resolved, That a committee of five be appointed by this Society, and be authorized to confer with committees from other medical societies with regard to the organization of a convention or congress of such societies, and report at the next meeting of this Society.

Resolved, That it is the sense of this Society that its welfare would be put in peril by any alliance or co-operation which would interfere with its autonomy or independent meeting.

These resolutions were adopted and the following committee subsequently appointed :

Drs. O. F. Wadsworth, of Boston ; C. B. Bull, of New York ; George C. Harlan, of Philadelphia ; Samuel Theobald, of Baltimore, and B. E. Fryer, of Kansas City.

Adjourned.

AFTERNOON SESSION.

The first paper of the afternoon session was

A REPORT OF 263 CASES OF CATARACT EXTRACTION, WITH PARTICULAR REFERENCE TO THE AFTER-TREATMENT,

by Dr. George Strawbridge, of Philadelphia.

The results had been as follows : Successful cases, 85.2 per cent. ; partial successes, 8.1 per cent., and failures, 6.7 per cent. Those cases were classed as failures in which fingers could not be counted at a distance of one or two feet. In twelve cases absolute loss of the eye occurred.

After the operation the eye was thoroughly cleansed, and for the past two years a solution of boracic acid (two per cent.) had been employed. The speaker's former plan had been, after applying a bandage, to put the patients to bed in a darkened room, keeping them in bed for four to six days. Two-thirds of the cases had been treated in this way. He had found this plan exceedingly debilitating in elderly individuals, and had gradually given up this plan, so that during the past six months the patients were, practically speaking, kept in bed only twenty-four hours. The room is as light as any ordinary room. If at the end of twenty-four hours everything is doing well, the patient is allowed to move about the room. No unsatisfactory result had followed this plan.

The speaker had employed in some cases cocaine. In one case in which a four per cent. solution was used, a violent inflammation began within twenty-four hours and resulted in total loss of the eye. Subsequently he had employed it without unpleasant results. His plan is to use a two per cent. solution, drop in one drop, wait a minute and drop in a second drop, and use only two drops.

He attaches much importance to stimulation after the operation. In elderly people the use of whiskey is begun a few hours after the operation.

Dr. H. Knapp, of New York, read a paper on

CATARACT EXTRACTION WITHOUT IRIDECTOMY.

He had performed this operation six times. Three of these had made ideal recoveries, with clear, central, movable pupil. The other three had more or less posterior synechia. Vision was fair, and could be rendered excellent by a simple needling if remaining insufficient.

He follows Panas in the performance of the operation : Large section along the upper margin of the cornea ; free laceration of the capsule ; expulsion of the cataract and

its remnants; reduction of the iris with a probe, if it did not occur spontaneously. Before the operation the eye is fully cocainized. After the expulsion of the lens, a small quantity of an antiseptic is injected into the anterior chamber, and eserine instilled into the conjunctival sac. The speaker believed that the chief advantage of this operation lies in the possibility of keeping the wound perfectly free from foreign substances, including portions of the lens, capsule, and iris.

Dr. David Webster, of New York, read a paper on

REPORT OF FIFTY CASES OF CATARACT EXTRACTION.

The results obtained were: Successes, 82 per cent.; partial successes, 12 per cent.; failures, 6 per cent.

Aseptic precautions were used in all the operations. The best vision obtained in any case was $\frac{20}{20}$. Dr. Webster advocated the extraction of both lenses at the same sitting in judiciously selected cases.

Dr. Webster also related the history of a case in which he had relieved the pain in a glaucoma absolutum by lacerating the infra-trochlear nerve (Badol's operation).

Dr. Henry D. Noyes, of New York, read a paper on

DEATH OF A PATIENT ON THE FIFTH DAY AFTER THE EXTRACTION OF A HARD CATARACT.

On Sunday morning the operation, which was perfectly satisfactory, was performed, and the patient suddenly died the following Friday morning. The only lesions found at the autopsy were dilatation of the heart and insufficiency of the valves of the left side. The death seems to have been due to heart-failure. Ten sections of the eyeball were exhibited. Inspection of the eye before death showed that the union was smooth and apparently perfect. What was particularly interesting was that the union appears to have taken place exclusively through the medium of the epithelial layer.

Dr. B. Joy Jeffries, of Boston, recommended that in cataract extractions cocaine be instilled into both eyes. This renders the eye quiet, and the patient can keep it open.

Dr. W. F. Mittendorf, of New York, thought that one reason bad results are obtained, was because the eye is left exposed to the air after the introduction of the cocaine solution. Recent observations show that the injurious action of cocaine is especially upon the epithelial layer, and in shutting off the supply of lymph fluid. The epithelium suffers very rapidly from lack of moisture, especially if the eye is kept open. It has been recommended to close the eye immediately after the introduction of cocaine. He employed a solution of the strength of one or two grains of cocaine to half an ounce of water.

Dr. Emil Greuning, of New York, had performed extraction without iridectomy in two cases. One was entirely successful, but in the other prolapse of the iris occurred.

Dr. H. D. Noyes, of New York, had performed extraction without iridectomy in six cases. In three of the six cases there was perfect union with a central circular pupil, and accurate vision. In one case intra-ocular hemorrhage came on twelve hours after operation. In two cases prolapse of the iris occurred. The prolapsed iris was excised, and in one case the result was entirely satisfactory. In the second case no satisfactory vision was obtained.

The speaker thought that the cases for this operation must be carefully selected. If the patient had but one eye he thought that he should operate on it with a preceding iridectomy, and not without. His belief was that a satisfactory result could be more certainly secured with iridectomy.

Dr. B. E. Fryer, of Kansas City, suggested the use of cocaine by inserting one drop every half hour until four or five drops have been used. In this way the iris becomes completely anæsthetized, and where we wish to perform iridectomy this is important.

The next paper was entitled

SOME MEDICO-LEGAL CASES,

by S. Joy Jeffries, M.D., of Boston.

Dr. Charles A. Oliver, of Philadelphia, exhibited and read a description of a new series of loose wools for the scientific detection of subnormal color-perception (color-blindness).

The following advantages are claimed for the series: That there are five tests; that the wools are loose and all of the colors of the same relative intensity; that each skein has its value expressed so that they can be employed by any intelligent layman; that accurate notings of color-changes can be made for future comparison, and proper verbal and written expression can be given; that by reason of the wools all being made of the same grade of manufacture, and all the colorings obtained from vegetable dies, no results can be gotten from the supplemental use of touch; and, finally, that a black surface is employed and no definite order of testing need be pursued.

Dr. William S. Dennett, of New York, exhibited a set of Holmgreen's worsteds, which had been made into spheres.

Adjourned until evening.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 1, 1886.

T. Mitchell Prudden, M.D., Vice-President, in the Chair.

Dr. W. Gill Wylie presented, on behalf of a candidate, a specimen of *chronic salpingitis with dilatation of the tubes and cystic ovaries.*

Dr. F. Ferguson presented mounted specimens of

FAT EMBOLI

removed from the lungs and organs of a man thirty-seven years of age, a native of Sweden and a sailor by occupation. On the 8th inst. he fell into the hold of a ship, a distance of twenty feet. He sustained a comminuted fracture of the lower third of his right thigh (not compound) and a compound comminuted fracture of the lower end of the right humerus. There were comminuted fractures of the rami of the pubes and ischium on the right side. There were no special injuries to the organs within the thorax and abdomen. There was a large quantity of blood beneath the pelvic peritoneum. The skull and brain were not injured.

He fell at 6.30 of the above date, and was admitted into New York Hospital shortly after the accident, where he died eight hours subsequently.

His pulse was irregular at times, and 75 to 80 a minute. His breathing was shallow and frequent and he suffered intense pain, especially from the injury of his right arm.

He was drowsy most of the time while in the hospital, but would readily arouse in answer to questions.

The lungs were anæmic; numerous sections of organs showed areas of capillaries filled with fat.

One of the sections was stained with osmic acid, the fat was seen colored black; the other section was mounted in three-fourths of one per cent. chloride of sodium solution.

[illegible]

Dr. W. Gill Wylie presented a series of specimens. One year ago he had reported to the Society twenty-five cases, in which he had operated for the removal of diseased tubes and ovaries. Since that time he had operated in twenty-eight cases, and in all except two recovery took place. The two fatal cases were complicated, one by acute abscess at the end of the tube and in the tissues around it, and the other by hæmatoma of the ovary, the contents of which were similar to retained menstrual

fluid, and so tarry in consistence that it was impossible to wash it away from the peritoneum, the sac having ruptured while being removed. Just how much this had to do with the fatal septicæmia which followed the operation Dr. Wylie was unable to say.

In more than one-half of the cases there was distinct pyo-salpinx; in the others the tubes contained a coffee-colored fluid; the ends of the tubes were closed and the ovaries were cystic, the cysts varying in size from that of a pea to that of an orange. Occasionally cystic degeneration of the ovaries was found without closure of the tubes, but usually in those cases it was associated with small imperfectly developed organs of generation. There was one specimen of *hæmato-salpinx*, a rare occurrence. Nearly all the cases gave a history of gonorrhœa. One specimen illustrated *fibroid degeneration of the ovary*, an exceedingly rare condition.

Dr. Amidon asked concerning the result of the operation in the cases of hystero-epilepsy.

Dr. Wylie said he had seen some of the cases operated upon a year ago, and in one patient no benefit had been afforded; but with that exception the results had been very satisfactory, more so, certainly, than he had expected. He recalled one case in which at the end of eight or nine months the patient regarded herself as entirely cured. In two cases the progress toward a cure was slow, until he dilated the uterus thoroughly, when the symptoms were removed entirely. Although some of the patients had had nervous symptoms for a few months after the operation, he had yet to see the patient, when the operation had been performed early, who had not been cured. In those cases in which the reflex attacks were associated more or less with menstruation or disorders of the internal generative organs the patients certainly were curable.

Dr. Putnam-Jacobi asked Dr. Wylie if he would remove the ovaries when there was no objective sign of disease of those organs.

Dr. Wylie said that he would not do so in very many cases. But if a young girl, who had to work for her living, was so afflicted that it became necessary for her to either be in her bed or to enter a hospital a certain portion of every month, he would not hesitate to open the abdomen and look at the ovaries, but if they were of normal size and showed no abnormal cyst, he would not remove them.

Dr. Putnam-Jacobi thought it worthy of mention, that in Charcot's latest work on hystero-epilepsy there was an entire absence of reference to uterine, ovarian, or any pelvic disease as causes of this nervous affection.

Dr. E. M. Cushier presented specimens of

MULTIPLE CARCINOMA

removed from the body of a woman twenty-six years of age, married, and the mother of three children, the youngest being one year of age. Her menses appeared at the age of fifteen; had always been irregular, painless, and she had menstruated irregularly since the birth of the last child. Three months ago the patient noticed a lump in the left side of her abdomen, which occasioned much pain. On entering the infirmary she was pale, cachectic, and feeble, and the abdominal tumor reached three fingers' breadth above the pubis, and to the left side. The enlargement was very sensitive, both to external pressure and pelvic examination. The position of the uterus could not be made out on account of the pain given by manipulation. Dr. Cushier decided that an exploratory incision was not admissible. The patient remained in the infirmary, failed gradually, complained of pain in the abdomen, and occasionally of stitching pains in the chest.

On May 10th she had a violent convulsion, which lasted fifteen minutes, and from which she passed into a half-unconscious condition. No further convulsion occurred, and the patient was merely apathetic.

On May 15th external strabismus of the left eye was noticed, and on the following day the pupil of the left eye was widely dilated, while that of the right eye was normal.

At no time was there any paralysis of either the face or the body. The patient remained semi-comatose, passed urine involuntarily, and died on May 17th.

The autopsy revealed a tumor closely adherent to the peritoneum and all the pelvic tissues, dark in color, parts of it soft, and the softened portions contained hemorrhagic spots. The uterus could be felt below and in front. The right fallopian tube remained intact, but the right ovary had undergone degeneration, and the mass had projected over to the left side, causing it to appear as if it was an enlargement of the left ovary. The left ovary was normal. A large nodule was found in the lower border of the liver. The kidneys contained two small nodules. The lungs were studded with nodules, varying in size, the largest being nearly three-fourths of an inch in diameter. The bronchial glands were enlarged, and these during life gave rise to marked hoarseness. The heart was normal. The brain was examined by Dr. Putnam-Jacobi, who would present the specimen.

Microscopical examination of the new growth in the ovary, the liver, the kidneys, and the lungs had been made, and the diagnosis was *medullary carcinoma*.

Dr. Putnam-Jacobi presented the brain, which contained a tumor that in its fresh state presented the appearance of carcinoma. It was situated in the posterior part of the second and third temporal convolutions of the left hemisphere, occupying nearly one-half of the second and about one-third of the third. The surrounding tissue was considerably œdematous. There was also a small nodule situated in the cuneus of the same hemisphere, in very nearly the locality which has recently been demonstrated to be the visual centre. There was another nodule at the posterior limit of the occipital gyrus.

Dr. Putnam-Jacobi regarded it as peculiar that the patient presented no cerebral symptoms until a few days before death, and that the convulsion was apparently not due to the tumor, but to another lesion occupying the opposite hemisphere, and consisting of a hemorrhage into the posterior gyrus, and encroaching upon the caudate nucleus of the right side of the brain.

The tumor occupied the region which has been said to give rise to blindness, and yet nothing of that kind was present during life. A remarkable circumstance was its latency, although the temporal lobe was where such tumors were most frequently found.

The meninges were normal.

Dr. Amidon asked if the cerebral tumor was vascular at the time the autopsy was made?

Dr. Putnam-Jacobi replied that it was excessively so.

Dr. Amidon remarked that a vascular tumor in this locality, one which might during life exert pressure, could have given rise to word-deafness, and he would ask if any hesitancy in speech or in answering questions was noticed, or any incoherence?

Dr. Cushier said that nothing of this kind was noticed. The patient merely was stupid, but answered readily.

Dr. Amidon said his faith in localization was so great that he should be inclined to think that something of the stupidity was word-deafness.

Dr. Ferguson asked how frequently secondary carcinomatous deposits were found in the brain.

Dr. Putnam-Jacobi thought that primary carcinoma of the brain was more frequent than secondary.

Dr. Ferguson said that he had seen only one case of primary carcinoma of the brain, and in that instance there were about a dozen small tumors, varying in size from a pin's head to a small pea, and they presented the ordinary features of the primary growth.

The specimen was referred to the Committee on Microscopy.

Dr. E. N. Liell presented a

DERMOID CYST OF THE OVARY

taken from a woman, sixty-nine years of age, [illegible] the mother of three children, and whose menopause occurred twenty years ago. She was perfectly well up to last March. At that time she noticed a gradual enlargement of her abdomen, with more or less of pain, increasing in severity in proportion to the increase in the size of abdomen, but thinking that it was nothing except tympanites, she did not consult a physician until one month ago, by whom she was referred to Dr. H. Marion Sims. At that time there was some œdema of the lower extremities. There was also more or less nausea and dyspnœa, produced by pressure of the tumor. All these symptoms gradually increased in severity up to the date of the operation, June 9th, which was performed by Dr. Sims, Dr. Liell assisting. The diagnosis was ovarian cyst, either dermoid or multilocular. The operation demonstrated it to be a dermoid tumor, weighing nearly seventy pounds, consisting of a gelatinous bloody fluid and a solid mass, with more or less of sloughing tissue and several large pieces of bone. The operation having been performed only three hours previously, the specimen had not been examined thoroughly for hair and teeth.

The pedicle was ligated with rubber, and according to the extra-peritoneal method. The specimen was interesting, especially with reference to its contents and the rapidity of its growth.

At seven o'clock the patient had rallied very well, her temperature being normal, and pulse 94.

The specimen was referred to the Committee on Microscopy.

The Society then went into executive session.

Correspondence.

OUR LONDON LETTER.

[illegible]

ABSCESS IN THE URETHRO-VAGINAL SEPTUM—THE UTERINE BRUIT—THE JUBILEE FESTIVAL OF THE BRITISH MEDICAL BENEVOLENT FUND—HOSPITAL SUNDAY AND SATURDAY—THE MEDICAL MANAGEMENT OF [illegible] SCHOOLS—THE POSTAL MICROSCOPICAL SOCIETY.

[illegible]

At the last meeting of the Obstetrical Society Dr. Herman, Obstetric Physician to the London Hospital, narrated the particulars of a case of chronic abscess of the female urethra which had come under his observation. The patient was forty-seven years of age and had suffered from dysuria, dyspareunia, and irritability of the bladder, the symptoms gradually increasing in severity. There was a tender swelling between the urethra and the vagina which burst and discharged pus into the urethra. The cavity was found to be about half the size of a walnut, and it soon contracted and healed after cauterization of its interior with nitrate of silver. Dr. Herman remarked that such an abscess might be either due to chronic congestion of the urethra or to suppuration of a cyst. He did not think his case was an example of the latter. The rarity of the affection was remarked on, Dr. Herman stating that he had only been able to find three cases on record. Dr. Matthews Duncan said he had seen many abscesses in the recto-vaginal septum, but remembered none in the urethro-vaginal septum. Dr. Gervis said he could only recall one case, and Mr. Knowsley Thornton said he had only seen a few cases of the kind.

Dr. Champneys, Obstetric Physician to St. George's Hospital, then read a paper embodying the results of a series of observations made by himself on the uterine, or, as it is sometimes termed, the placental *bruit* or *souffle*. He had heard it on the left side in thirty-three cases; on the right side in one. In five cases he had heard it after the expulsion of the placenta, but in these cases its point of greatest intensity had sunk down after delivery. A pulsating artery was felt in the vagina in five cases, but pressure on it affected the *bruit* in one case only. The author considered that the preponderance of left- over right-sided *bruits* confirmed the view that the *bruit* was produced in the arteries as they reached the uterus, or soon after, as, owing to the twisting of the uterus so that its anterior surface looked toward the right side, the left cornu was anterior to the right cornu.

Dr. Herman remarked that the variations in loudness of the murmur were of much importance in its identification. There was no kind of abdominal enlargement in which a murmur, having rhythmical variations in loudness, was heard, except that produced by uterine tumors. The presence of such a murmur, therefore, showed that the tumor was uterine, but did not give any further information as to its nature.

Dr. Amand Routh, Assistant Obstetric Physician to Charing Cross Hospital, referred to a case in which, by means of vaginal stethoscopy, the uterine *souffle* was proved to exist two or three weeks after the presumed death of the fœtus, which (labor having been induced for uncontrollable vomiting) was found to be mummified. In this case the *souffle* was inaudible over the abdomen, and Dr. A. Routh remarked that he had frequently heard the *souffle* through the vagina, by vaginal stethoscopy over the cervix uteri, when it was inaudible over the abdomen.

The Hospital Sunday Fund has produced about thirty-five thousand pounds. The jubilee festival of the British Medical Benevolent Fund has produced £3,500. Yet the former appealed for contributions to the population at large, and the latter only to a profession of some twenty-five thousand members. The result shows the truth of the old adage, that it is safer to apply to anyone for a favor who has previously granted you one than to a person who is indebted to you for previous favors. The medical profession already do gratuitous medical work in hospitals, dispensaries, and private practice to the total value of many thousand pounds annually, and yet, when appealed to, they can raise a very handsome sum for distribution among unfortunate brother-practitioners.

It would be putting a very moderate estimate upon the value of professional services to suggest that every medical man gives his professional services gratuitously to the value of two pounds annually. Yet, if this be accepted as a fair estimate, the entire profession does work for nothing to the extent of fifty thousand pounds a year, a sum which I very much doubt will be exceeded by the Hospital Sunday and Saturday Funds of this year put together. Yet some medical men are called grasping!

An animated correspondence has been recently going on in *The Times* respecting an outbreak of infectious disease at a public school. Amidst the wordy strife which has been carried on, it is possible to pick out certain very unpleasant facts. A schoolboy having gone home for a few days' holiday, informed his father that there had been cases of diphtheria in the school. His father had been informed of the occurrence of cases of measles in the school, but on finding that diphtheria was also prevalent he naturally felt alarmed. On the return of the boy to school he found that a death from diphtheria had occurred, and his father, on learning this, removed him from the school, although warned that if he did so he could not again send him to the school. What defence the head-master may be able to make to the charge brought against him remains to be seen. It may be noted that the medical attendant to the school is the son of the head-master, and the latter was, therefore, presumably kept informed of medical matters affecting the school. This renders the more inexcusable the deplorable neglect which seems to have occurred.

A very unostentatious, but withal very useful, little society is the Postal Microscopical Society. This has now been in working order for some years, and its work-

ing is intimately known to me. Its members send slides round for mutual studies at fortnightly intervals. A notebook accompanies the box of slides, and very full notes are frequently made on good specimens. The book and slide-box travel by Parcel Post for the small sum of threepence. A medical section exists, in which only anatomical and pathological specimens are circulated. The extent of the operations of the Society may be gauged when I mention that it has members beyond the United Kingdom and, out of an annual subscription of only ten shillings, supports a quarterly journal.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE FORMATION OF CRYSTALS IN THE ANIMAL ORGANISM —THE ACTION OF PELLETIERINE ON THE MOTOR NERVES OF THE EYE—THE TREATMENT OF DISEASES BY OPERATIVE MEASURES—RADICAL PROCEDURES FOR TRIVIAL AFFECTIONS—ONE UTERUS AND ONE KIDNEY LESS, AND TWO LUCKY PATIENTS.

PARIS, [illegible]

DR. GALIPPE stated, at a recent meeting of the Biological Society of Paris, that the existing theories for explaining the formation of crystals in the animal organism are not satisfactory, though he believes that micro-organisms have some influence on the formation of these salts. From researches made with dental tartar, Dr. Galippe has discovered that it always contains micro-organisms which, when sown and cultivated, are constantly attended with identical results. He concludes that probably these micro-organisms are factors in the formation of salivary calculi. In the centre of these calculi there is always some foreign body, such as a hair or a fish-bone. He does not believe that the foreign body is a centre of crystallization, but that micro-organisms are carried along with it into the salivary canal; there, by chemical action, they become agents in the formation of a deposit of mineral salt; hence the necessity for rinsing the mouth frequently, and particularly after meals, with an alkaline solution. Dr. Galippe also met with micro-organisms in biliary and vesical calculi.

Dr. Galezowski lately read a paper before the Paris Academy of Medicine on the action of pelletierine on the motor nerves of the eye. His researches were based on the ocular disturbance which occurs in subjects who absorb this substance, and who are affected with diplopia. The observation of this fact has induced Dr. Galezowski to prescribe pelletierine in cases of paralysis of the third and sixth pairs of nerves. Iodide of potassium and blisters failed where pelletierine cured. The preparation used was the syrup of pelletierine, in the proportion of one gramme to one hundred and twenty grammes of syrup. From three to six doses of a tablespoonful each were administered daily. But this substance being excessively dear, Dr. Galezowski proposes to meet this difficulty by administering it in subcutaneous injections.

The growing tendency in the profession to treat all diseases by surgical or operative measures is becoming more and more evident. In some cases they are no doubt justifiable, but in others they are very questionable. At the meeting of the Academy of Medicine last week, Dr. Gustave Richelot, son of the celebrated physician of that name, made a communication on a case of vaginal hysterectomy which he had performed on a young woman for the cure of retroversion of the uterus. Dr. Richelot had already more than once performed this operation for the cure of primary cancer of the body and neck of the womb, but whether he is justified in resorting to such a severe or radical measure in the case under notice time alone will tell. The case was that of a young woman, aged twenty-six, who was admitted into the Saint-Antoine Hospital about the beginning of April last. She was extremely anæmiated and emaciated, and her face was bony and of a waxy complexion. She suffered intense and continual pain in the pelvic region, which was aggravated at each menstrual period and attended with great difficulty in walking. On examination the uterus, which was slightly increased in size, was found in retroflexion, the body occupying the posterior vaginal cul-de-sac. The neck was in its normal position, and presented no lesions of any importance. The organ, in its *ensemble*, was sufficiently mobile, and nothing indicated that it was fixed by adhesions. With the author, it is difficult to understand how a simple uterine displacement, without any notable hypertrophy, without fibroma, without evident compression of the pelvic organs, could bring about such functional troubles and a general state of health so lamentable. And yet, without further consideration, Dr. Richelot decided upon removing the entire uterus, which radical operation he thought was necessary for the safety of the patient's life, as every attempt at permanently reducing the retroflexion had failed. The operation was performed on April 28th, and on June 3d the patient was reported as completely cured. The operation was attended with little or no hemorrhage, and no complication followed. Dr. Richelot attributed this remarkable success of the operation to the employment of a solution of the bichloride of mercury (1 to 1,000), with which he irrigated the vagina before and after the operation, and to the employment of a special kind of forceps, eight in number, applying continual pressure, and which, being of sufficient length, he left suspended from the wounded arteries for forty-eight hours.

After Dr. Richelot, Dr. Polaillon mounted the tribune and read a paper on an operation he had performed which was equally as radical as the preceding one, and under almost similar circumstances—that is, as far as the justifiableness or otherwise of the operation was concerned. The operation was nephrectomy, for the removal of a floating and painful kidney in a young woman who had been the subject of this infirmity for two years. As the author stated, the indication for removing a floating kidney is extremely rare, as the mobility of the kidney has ordinarily no influence on the health. It merely constitutes an inconvenience or annoyance more or less great, which may be remedied by a belt or other appropriate apparatus; and if the patient leads a sedentary life, he or she might reach the term of a natural career without any suffering. This immunity is not always enjoyed by the subjects of floating kidneys, and sometimes they suffer so much pain that they are obliged to lay up. Surgical intervention is indicated only when the pains are violent and rebellious to medical and orthopedic measures, and if the health is much affected, as was the case with the patient above referred to. After five months' observation in his own ward at La Pitié Hospital, Dr. Polaillon, finding no amendment in the state of health of the patient, decided upon removing the offending organ, which he did about two months ago. It was the right kidney, which was so mobile that it could be felt in almost every part of the abdomen, and could be seized between the fingers. Believing that he had to do with a kidney with a long pedicle, the operator practised a laparotomy on the median line, when he discovered that the organ moved in the loose connective tissue in the retro-peritoneal space. It was then necessary, in order to bring the kidney to view, to draw aside a portion of the small intestine. No untoward symptom supervened, and the patient was cured in a fortnight.

ACUTE POISONING FROM SARDINES.

[illegible] Jan. 1886.

SIR: A family living near this city purchased a box of sardines. A young lady of the family ate one or two on Sunday evening, and all through that night suffered from violent nausea, vomiting, colic, and finally diarrhœa. The cause of the trouble was not suspected, and two days later seven members of the family, including two servants and a child two and one-half years of age, ate from the

same box. Two or three hours after this they began to suffer from nausea and vomiting, followed in some cases by profuse painless watery discharges. One of the servants, a woman aged forty, was brought into a condition of collapse, and for a time there were even fears of her life. The little child only took one very small taste. She suffered, nevertheless, from nausea and vomiting for a few hours only. The effect of the poisoning was very prostrating, it being nearly a week before all had recovered strength. Very little actual pain was felt.

The sardines tasted well, and showed no signs of decomposition. They were supposed to be of the best quality.

I have had no opportunity of having the remaining fish examined, and write in hopes that some of your readers can tell me what was the matter. Was it ptomaines or tin? Yours, M. C.

New York City, July [illegible], 1886.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 25 to July 31, 1886.

BROWN, JOSEPH B., Colonel and Surgeon. Retired from active service, July 26, 1886. S. O. 171, A. G. O., July 26, 1886.

GIBSON, J. R., Major and Surgeon. Ordered from Department of the East to Department of Missouri on expiration of leave of absence granted in S. O. 158 c. s., A. G. O. S. O. 168, A. G. O., July 22, 1886.

BENTLEY, EDWIN, Major and Surgeon. Ordered for duty as Post Surgeon at Fort Davis, Tex. S. O. 92, Department of Texas, July 22, 1886.

TAYLOR, M. K., Major and Surgeon. Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 77, Department of Missouri, July 24, 1886.

MIDDLETON, PASSMORE, Major and Surgeon. Ordered to Department of the East from Department of Missouri. S. O. 168, A. G. O., July 22, 1886.

GIRARD, JOSEPH B., Captain and Assistant Surgeon. Granted leave of absence for three months, with permission to go beyond sea. S. O. 170, A. G. O., July 24, 1886.

ROBINSON, SAMUEL Q., Captain and Assistant Surgeon. Ordered for duty as Post Surgeon at Fort Brown, Tex. S. O. 92, Department of Texas, July 22, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ended July 31, 1886.

LUMSDEN, G. P., Passed Assistant Surgeon. Ordered to duty at Marine Barracks, Washington, D. C., for the month of August.

CORDEIRO, F. J. B., Assistant Surgeon. Ordered to Receiving Ship Minnesota.

LAPAROTOMY FOR ACUTE SUPPURATIVE PERITONITIS.—At a meeting of the Zurich Medical Society, Professor Kroenlein reported three cases of laparotomy for acute diffuse purulent peritonitis. One of his patients, a lad aged seventeen, with perforation of the vermiform appendix, died from collapse two days after the operation. Another, a man aged sixty-one, with perforation of the small bowel and extreme collapse, survived only a few hours. But the third patient, aged eighteen, made a satisfactory recovery, though his state at the time of the operation was extremely grave.—*Brit. Med. Journ.*

Medical Items.

CONTAGIOUS DISEASES [illegible] WEEK [illegible]. The report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 31, 1886:

	Cases.	Deaths.
Typhus fever ..		
[illegible]		
Scarlet fever...		
[illegible]		
[illegible]		
Diphtheria		
Small-pox		

ICE-CREAM POISONING.—Dr. J. W. Kales, of Franklinville, N. Y., writes: "I have read with care your editorial and the letter of Dr. Morrow upon the above subject. Some four years ago I had considerable experience with the so-called victims of poisoned ice-cream and the lengthy legal investigation which followed. At that time I carefully searched all the available literature bearing upon the subject, and since have carefully watched the numerous reports of wholesale poisoning that have appeared in the press. The symptoms—acute gastro-intestinal irritation—are always the same. That there are in every hamlet men who will wilfully mingle poison in food I do not believe, nor do I believe that the extract is at fault. If vanillism is the cause, why do we not have cases caused by drinking soda-water? For vanilla is a popular flavor. Why do we not have cases at our fashionable hotels where cream is served? I do not wish to detract from any man's labors, but I do believe that the cause, or rather causes, of the poisoning can be attributed, not to poor gelatine, vanillism, coumarin, or tyrotoxcin, but to the manner in which the cream is partaken. Every law of digestion is violated at the so-called 'ice-cream' festival. Every fellow takes particular delight in gorging himself and his 'best girl,' not only with ice-cream, cake, candy, etc., but with every variety of indigestible substance. This process goes on for two or more hours, when outraged nature comes to the rescue and the indigestible matter is expelled with all the symptoms of acute gastro-intestinal irritation. It only excites the public because so large a company are sick, or poisoned if you wish, at the same time. Have we not seen isolated cases, presenting exactly the same symptoms, caused by eating oysters and other food and drinking ice-water? I have. What are the causes of cholera morbus, summer diarrhœa, etc.? Are they other than those of ice-cream poisoning? I say that they are the same. I have arrived at this conclusion after some experience and much study. If any person can convince me of error I trust that he will produce the proof. I am open to conviction."

A CURE FOR TOOTHACHE FROM DENTAL CARIES.—Dr. V. Gsell-Feltz, of St. Gallen, warmly recommends, in toothache from dental caries, the application of cotton-wool soaked in an oily fluid obtained by melting together five grammes of camphor, five grammes of chloral, and one gramme of cocaine. Relief is complete and lasting.

IN HÆMORRHOIDAL TUMORS five drops of a ten per cent. solution of phenic acid injected into the swelled veins almost immediately withers it up. Dr. Menière employs the following formula, which he esteems superior to the simple solution, as the pain, which otherwise is often severe, is greatly lessened: Glycerine, two drachms and a half; phenic acid, twenty drops; morphia, five grains.

WHAT can't be cured must be treated at the usual rates.

ANT VAGINITIS.—To the Obstetrical Society of New York, Dr. Gillette reported the case of a patient who applied to him complaining of irritation of the vulva and vagina, accompanied by profuse leucorrhœa. On examination the vulvo-vaginal mucous membrane was found to be much inflamed and bathed in pus. Vaginal injections were ordered, but the patient objected to them, saying that they always made her worse. A few days later she reported again, and said that she had discovered the cause of her trouble, viz.: Red ants had taken up their abode in her fountain-syringe, and every time she used the syringe the ants were poured into the vagina. Their bites undoubtedly caused the inflammation. He related the case merely to offer a new cause of vaginitis.

PAPER SPOONS FOR EYE-DROPS.—Dr. F. A. A. Smith writes to the *British Medical Journal:* "Most instruments used for placing drops on the eye have their disadvantages. They cost money; the hairs from brushes may be left behind, quills and glass-droppers are dangerous in inexperienced hands, bits of rag are dirty, etc. I have been for many years in the habit of directing patients to make their own droppers, by simply cutting a piece of clean paper in the form of a little spoon. These spoons are made in a few seconds, and are costless. A clean spoon may be used every time that drops are used. Being made of soft paper, no harm can be done to the eye."

COMPLIMENTARY TO WASHINGTON DOCTORS.—The Washington correspondent of a Western daily says: "Congressmen get queer letters sometimes. The other day a Western member showed me the following: 'Dear Sir: My children have been afflicted with the scabs all winter, and the medicine given them by the doctor here does not seem to do any good. I see by the papers that there are some very fine doctors in Washington connected with the Government, and if it does not cost too much I wish you would ask them what is good for the scabs and write me by return mail.'"

THE INTERNATIONAL MEDICAL CONGRESS.—A well-known American physician writes to us from Berlin, under date of June 30th, that he has lately come in contact with prominent members of the profession in that city, Bremen, Hamburg, Dresden, Munich, Vienna, and Breslau, and that everywhere the leading questions were: "What about the Congress of 1887? Will it be held? Will it be a success? Will you be there? How much reduction will there be in the passage rates? Is it to be managed by homœopaths? Have the dissensions which threatened to wreck the Congress been adjusted? Whom shall we meet whom we know?" etc. To these queries he felt it his duty to answer: "The Congress will surely be held. Whether it will be a success cannot now be foretold. I shall not be there. So far as I know there will be no reduction in fares to America. The homœopaths have nothing whatever to do with the Congress. The dissensions have not been adjusted in any sense whatever. You will be likely to meet chiefly men whom you do not know by name or fame, since the majority of the best-known men in the United States have withdrawn from the Congress because they do not approve of the way in which it is managed." "With but few exceptions," he adds, "I found very little inclination to incur the trouble and expense of a trip across under such discouraging auspices. My replies only corroborated previous impressions."—*New York Medical Journal.*

TRACHEOTOMY FOR HÆMOPTYSIS has, fortunately perhaps, never been performed but twice. The second and last case was that of a woman, thirty-four years of age, brought to Professor Wyss' clinic at Zurich with acute anæmia, caused by profuse hæmoptysis, and in whom, about four weeks later, within ten minutes after a fresh severe hemorrhage, tracheotomy was performed. About fifty cubic centimetres of arterial blood were then aspirated (with a catheter) through the wound. The procedure at once relieved the urgent inspiratory dyspnœa and deep cyanosis, and removed the unconscious state (all of which symptoms were ascribed solely to the presence of considerable quantities of blood in the bronchi and trachea). Four days later, however, the woman died from purulent mediastinitis, starting from the tracheal wound.

IODOL IN OCULAR DISEASES.—At the Société de Thérapeutique, M. Paul read a note on iodol in reference to ocular diseases. This body, which contains eighty-five per cent. of iodine, gave him great satisfaction in cases of chronic blepharitis and conjunctivitis. He uses the following formula, and considers it superior to yellow precipitate: Vaseline, iodol, āā 3 iij.

THE TREATMENT OF MASTITIS BY REST AND COMPRESSION.—We have received a letter addressed by Dr. Wm. H. Doughty, of Augusta, Ga., to Dr. J. A. Post, of Lansing, Mich., and sent by request of the latter gentleman to THE RECORD for publication. The writer, referring to Dr. Post's letter published in these columns under date of November 21, 1885, says: "I have just read your defence of the claim of Dr. Ranney, of your city, to priority and originality in the treatment of mastitis by rest and compression, and by the use of the many-tailed bandage. Allow me to throw a little light on the subject of this disputed claim. You trace Dr. Ranney's claim as far back as 1866. This practice has been taught and pursued in this locality for thirty or more years. In 1853 and 1854, when in attendance upon the lectures at the Medical College of Georgia, I was taught by the distinguished Professor of Surgery, the late L. A. Dugas, M.D., LL.D., to adopt and prefer this method of treatment, and, with few exceptions, have employed it ever since. I presume he was the originator of this simple and effective mode of managing this very serious trouble to lying-in women, and do not doubt that a careful examination of the files of the *Southern Medical and Surgical Journal*, then one of the most influential journals of the South, published in this city, and of which he was for many years one of its most distinguished editors, would reveal an editorial or communication on the subject. He not only recommended the many-tailed bandage as the best and simplest, but, almost in the words of Dr. Ranney, advised it 'for the treatment of congested and inflamed breasts, and for the prevention of the secretion of milk when, on account of a still-birth, or death of the child after delivery, or for any other reason, it became necessary to diminish the augmented activity of the circulation, the tendency to tumefaction, inflammation, and its results, or to arrest the secretion of milk in the mammæ.' More than this, he specified its negative advantages in retiring the inflamed organ from sight and officious manipulation and filthy applications of every kind by patient or nurse, as of no little importance. This mode of treatment is so familiar here as no longer to possess a feature of novelty; indeed, it is rather a matter of surprise that a claim to its discovery should be made in these latter years by any physician from any quarter of the country." . . .

A SIMPLE METHOD OF PRESERVING DEAD BODIES.—Dr. M. Kennedy, of Bartow, Fla., writes for information as to the best, simplest, and most ready method of preserving dead bodies. He says: "Many who die in this State are from remote sections of the country, and the relatives and friends are anxious that the bodies should be so prepared, embalmed, as to preserve them to be viewed at their former homes. In most instances the medical attendant is called on to perform this operation. The meagre information to be had on the subject, and the bungling manner in which I have seen the attempt made, has induced me to call on the profession, through THE RECORD, for more light concerning the matter." The writer also asks what might be considered a reasonable fee for such services.

MEDICINE IN THE UNITED STATES, AND ITS RELATIONS TO CO-OPERATIVE INVESTIGATION.[1]

BY JOHN S. BILLINGS, M.D., LL.D. [illegible].

MR. PRESIDENT, AND GENTLEMEN OF THE BRITISH MEDICAL ASSOCIATION: You all know that the representative of the American medical profession first selected by your Executive Committee to deliver the address in medicine to-day, was the late Dr. Austin Flint, Sr., of New York, whose death last March is, therefore, a great and direct loss to you as well as to America. Every English physician knows Dr. Flint by reputation and through his writings; but only those few of you who were so fortunate as to know him personally can fully appreciate the magnitude of the loss which the medical profession has sustained in his death.

This is not the time and place to attempt to pronounce a fitting eulogium upon him and his work, and I shall, therefore, only say that my deep personal sorrow for his removal is mingled with sympathy for the members of this Association, who have been thus deprived of the pleasure of hearing him state in person some of the results of his long and wide experience. The loss is not a total one, it is true, since he had, fortunately, completed his address on "The Medicine of the Future," which has been published, and has, no doubt, been read by all of you; but in this case the printed page is by no means a satisfactory substitute for the spoken word.

In accepting the request with which I have been honored by your Council, that I should attempt to take his vacant place on this occasion, it is with a full understanding of my inability to fill it that I stand before you. Nevertheless, when your President sent me this invitation, and urged its acceptance on the ground that I could thus at least show my appreciation of the brotherly feeling toward the American medical profession which prompted those who gave it, it was not proper or possible to decline or to make excuse, and I can, therefore, only return thanks for the honor, and ask that under the circumstances you will be lenient in judgment upon what I shall present to you.

The request came at a time when I was hard pressed by official duties, and had neither leisure nor opportunity to undertake any special research; hence, to avoid violating one of my favorite Scotch maxims, viz., "That which you do not know, tell that not to any one," it was necessary to select some subject to which I had already given consideration, and which at the same time would probably be of interest to English physicians.

Reflection on these restrictions soon brought the field of selection into narrow limits, almost into "a small intercept of space of one dimension," as a mathematician would say.

What is the significance of this invitation extended for the first time to a physician of another country, and that country the United States, to come to this annual gathering of the medical men of Great Britain and give the address in medicine?

Does it not mean recognition of the unity of medicine, of the utility of co-operation, of the fact that we have common interests, and that the time has come when it is desirable to hear from the outlying younger branch of the family with a view to mutual pleasure and profit in the future? So it seems to me; and I propose, therefore, to call your attention briefly to some points relating to the present condition and future prospects of medicine in the United States, and to the direction in which you may reasonably hope and expect from that country, in the future, the most useful co-operation in the improvement of medical science and art. I believe that these must be matters of interest you, and that I can perhaps make clear certain peculiarities which do not seem to be as generally understood on this side of the Atlantic as it is desirable that they should be to insure sound judgment upon some of the results observed.

In the first place, permit me to call your attention to the fact that it is hardly possible to make any statements with regard to medicine in, or the medical profession of, the United States as a whole, which shall be definite, and at the same time distinctive; that is, which will not apply almost equally well to medicine and the medical profession in other countries. This is due to the fact that there are great differences in the organization of the profession in different parts of America, so that what is true of one State would not be true of another; what is required as to fitness or qualification to practise in one place is not required in another; and the country covers so many parallels of latitude and meridians of longitude, making the conditions of life so diverse, and producing such differences in the prevailing diseases, that a man who is fairly qualified to practise in one section may be poorly fitted to treat the endemic diseases of another.

As in painting a picture it is best to locate and define the shadows first, and deal with the lights afterward, let us begin by considering some of the things that American physicians complain about; in other words, some of their supposed grievances. One of these is that the profession is overcrowded; that there are too many doctors, both *in esse* and *in posse*, and that this is due to too low a standard of education, and to the want of legal restrictions as to the qualifications which shall give a man the right to practise. The feelings of some of our physicians on this subject are in full accord with those of the good old New England deacon who told the village scapegrace seeking admission that "he thought the church was about full."

Now what is the number and distribution of medical men in America? Statistics gathered in 1883,[2] showed that in the United States and Canada there were 90,410 persons calling themselves physicians, being in the proportion of 1 to every 600 of population. In Canada alone there were 3,487 physicians, or 1 to 1,112 of population. If we take the figures of our last census, of 1880, the proportion of physicians reported is 1 to 589 of population, or 17 per 10,000. In England and Wales, by the census of 1881, the proportion of physicians is only 5.8 per 10,000, but these figures are not properly comparable with those of the United States, because they do not include unregistered persons. If the same classes were included that are counted in the United States report, I presume that the proportion would be about 9 per 10,000, or a little more [illegible] United States.

[1] The American Address in Medicine, delivered before the British Medical Association, Montreal, August [illegible], 1886.

In the United States the proportion to the population of those who call themselves physicians varies greatly in different localities; thus in Colorado there are 29.3; in Indiana, 25.2; in Oregon, 24.3; and in Arkansas, 23.5 per 10,000; while in New Mexico there are only 6.6; in South Carolina, 9.2; and in North Carolina, 9.7 per 10,000.[1]

It is not so easy to give satisfactory reasons for these differences; we can only say that they do not depend, to any great extent, upon local legislation. The proportion of physicians is generally lowest in the Southern States lying east of the Mississippi, and highest in those regions where immigration has recently been active. If we compare, by localities, the proportion of physicians to the population with that of clergymen and lawyers, we find some curious differences. It seems that the lawyers of the United States number 12.7, while in England and Wales they are 6.6 per 10,000, but that on the other hand the clergymen are 14.6 in England and 12.8 in the United States per 10,000 of population. In many instances it seems that where the lawyers are most numerous the supply of clergymen is smallest. I believe that a fair proportion of physicians to population is about 1 per 1,000, which is not far from the actual proportion in England, while the true proportion of practising physicians in the United States is about 1 in 750. We must admit, then, that there is at all events no scarcity of physicians in the United States, and, as we have over eighty medical schools at work, besides a fair proportion of medical immigrants, there is no immediate danger of any interruption to the supply.

Let us now consider the second head of the complaint, viz., that the standard of education is too low. There is ground for this, considered with reference to some localities, but not for others. I said a moment ago that a man might be fairly qualified for practice in one part of the country and yet find himself at a loss in another. This needs a little explanation, which I can, perhaps, give most easily in connection with a map of the United States, which I here show you. This map which was prepared for a very different purpose, indicates by different shades of color the relative proportion of deaths reported as due to malarial disease to the total number of deaths in different parts of the country for the census year 1879–80. You will note how comparatively light the tint is in the North and Northeast, and how dark the shades become in the South and in the Valley of the Mississippi, thus indicating the great differences which exist as to the prevalence and deadly effects of the malarial poison in different sections of the country. It is in some of these low bottom lands and swampy districts that we meet with cases of congestive chills and of malarial hæmaturia, cases in which the patient has been described as being "a mere appendage to a huge malarial entity, an incident of a miasmatic cataclysm." Furthermore, this strip of land bordering on the Gulf-coast is in the yellow fever zone, and has, heretofore, been repeatedly desolated by this pestilence.

Chart I.—Map of the United States, showing the [illegible] from malaria, [illegible] deaths in known causes, Census of 1880. [illegible]

As compared with the North and East, much of this malarious region is a thinly settled country, an almost purely agricultural country, and not a rich country. I need hardly tell you that the physician who has received his chief clinical instruction in the office of his preceptor in Vermont or New Hampshire, supplemented by distant glimpses of a few cases in hospital in Boston or New York, will find himself at a loss at first in dealing with the emergencies of daily practice in Arkansas and Mississippi. He will be subjected to influences which at times are dangerous to one who is not acclimated, and which tend to produce depression of spirits, want of energy, and bad health. He will not have free and constant access to scientific companionship, nor be stimulated by the influence of learned societies, and he cannot avail himself of the ordinary sources of amusement, education, and rest, such as art galleries, the drama,

[1] [illegible] which the proportion of persons calling themselves physicians to the population in the [illegible] indicated by different shades of color.

libraries, and museums, etc., which are found only in the cities. Moreover, the pecuniary reward which the practitioner in many of these places can reasonably hope for is comparatively small.

Taking all these things into consideration, it is clear that if a man after spending from six to eight years, and from £1,000 to £2,000 in acquiring such a general and professional education as it is now considered that a skilled physician should possess, then settles in such a region, with the prospect of an average income of from £150 to £200 per year, it is not from pecuniary motives alone. There are such men in such places, men who are not only highly educated and skilled practitioners, but who are also original investigators and thinkers. It was within the limits of this malarial shadow that the foundation of modern gynecology was laid by Marion Sims, of abdominal surgery by McDowell, Battey and Gross, of an important part of the physiology of the nervous system by Campbell. Nevertheless the rule holds good that malaria and science are antagonistic; the exceptions prove the rule.

Nor can the inducements for highly educated physicians to settle in thinly settled localities be made stronger by any form of penal or restrictive legislation. Any attempt to fix a standard of requirements or qualifications for practice which shall be the same for such rural districts and for the large cities and manufacturing towns, must result in the adoption of what competent judges would consider so low a standard as to be ridiculous and useless. The demands are widely different, and corresponding differences exist in the sources of supply, that is, in the medical schools.

There is a class of medical schools in the United States whose object is to give the minimum amount of instruction which will enable a man to commence the practice of medicine without much danger of making such serious and glaring blunders as will be readily detected by the public. There are other schools whose aim and object is to make fairly well trained practitioners; the general character of the instruction given in these being substantially the same as that given in your English hospital medical schools. The results of such a three years' graded course of instruction in medicine as these schools furnish depend upon the character of the material upon which they work; that is to say, upon the general preliminary education possessed by the student at the time of his matriculation. This is evidently too often defective, and only a few schools have thus far ventured to establish any standard of preliminary examination which at all approaches in its demands that which is required in England.

The proverb that it does not pay to give a $5,000 education to a $5 boy is clearly of American origin, and sums up a great deal of experience.

You have nineteen portals of entrance to the profession and have not found it easy to keep them all up to the standard. In America we have over eighty gates, a number of turnstiles, and a good deal of the ground is unenclosed common. Many of our physicians are more or less dissatisfied with this state of things and with the results thereof, and every year in some States efforts are made to secure legislation which it is supposed will protect the interests of the profession, though those who advocate such legislation are usually prudent enough to claim as their only motive a desire for the protection of the public.

Now, how does this free trade in medicine and the low standard of qualification, or no standard at all, required by law affect practitioners as individuals? To answer this we must divide the profession into several classes. In the first place, in all our cities, great and small, there is a large class of physicians who are as well educated and as thoroughly competent to practise their art as can be found in the world. They have studied both at home and abroad, have had extensive clinical training, are always supplied with the latest and best medical literature and the most improved instruments, and many of them are connected with hospitals and medical schools. Among them are found the majority of our writers and teachers, and the successful men are the survivors of a struggle in which there has been keen and incessant competition. These physicians, whose positions are fairly assured, and who, as a rule, have all the practice they desire, are not usually active leaders in movements to secure medical legislation, although they passively assent to such efforts, or at least do not oppose them; and their names may sometimes be found appended to memorials urging such legislation. They are clear-headed, shrewd, "practical" men, who know that their business interests are not specially injured by quacks and ignoramuses, rather the contrary in fact, for they are called on to repair the damage done by the quack to people who have more money than brains; and they are not inclined to risk the fate of the Mexican donkey who died of "*congojas agenas*," that is, "of other people's troubles."

Then there is another large class of honest, hard-working practitioners who rely more on what they call experience and common-sense than on book learning. Many of these have obtained assured positions of respectability and usefulness, and are comparatively indifferent to medical legislation so far as their own interests are concerned. Others, however, who are not so successful, feel the competition of the local herb doctor or of the travelling quack more keenly, and have more decided views about the importance of diplomas. Among these are the young men who have not yet acquired local fame, and who are apt to become very indignant over the doings of some charlatan in the neighborhood, or of some druggist who prescribes over his counter. These last are usually quite clear in their minds that the State ought to interfere and prevent injury to the health of the people.

I have known two unsuccessful physicians who finally abandoned practice, and who gave as a reason for their failure—one that "he did not know enough," and the other that "he had not the manners and tact which would inspire confidence in his patients;" but such frank-speaking men are rare.

Thus far, as a rule, the efforts which have been made to secure legislation upon medical matters in America have come from the profession itself, and have been chiefly urged and recommended by physicians. The general public, and even the educated public, has shown very little interest in the matter. It does not demand protection against ignorance, but intrusts the care of its health and the lives of those who are nearest and dearest to it to almost any one who announces himself as prepared to take charge of them. The number of those who profess to practise medicine in the United States and are not qualified to do so is undoubtedly large, though by no means so large as one might suppose after listening to the impassioned eloquence which is duly aired every year upon the subject. There are some advertising charlatans, and travelling quacks are occasionally to be met with, but they are rare.

The most rigid tests of qualification, in our profession, in the United States, are those required of candidates for admission into the medical departments of the army and navy. The standard established for these is about the same as that for the corresponding corps of the English army and navy; and of the candidates who apply from seventy to eighty per cent. are rejected.

Certainly we must admit that this percentage indicates an unsatisfactory state of things. But what evidence have we as to its results upon the health and life of the people? What shall we take as the measures of the difference of skill in physicians? The death-rate? If we compare the death-rate of the United States with those of other civilized countries, we find that it is as low as any with the exception of Sweden. Does a low death-rate mean better sanitary condition or more skill among

the doctors? For the last twenty years the death-rate has been diminishing in England; the average amount of life for each person here has been increased; but I observe that the sanitarians claim this as proof of the value and importance of their efforts, and that nothing is said about its being in any way due to increase in medical skill or to improvements in medical science. Evidently this test is not a convincing one. Almost the only matter in which figures seem to demonstrate the importance of superior medical education and skill is in the statistics of deaths due to childbirth and of the results of surgical operations.

The proportion of deaths from childbirth to the number of births is decidedly greater in the rural districts than in large cities, and among the colored than among the white population. If this difference were found only in the United States statistics it might be accounted for by the differences in the trustworthiness of the sources from which the data are derived; but we find similar differences in England, and we must admit that these are probably largely due to the fact that in cities labor cases receive more prompt and efficient professional care than they do in the country. I need hardly call your attention to the results of antiseptic surgery, or of modern abdominal surgery, as compared with those of twenty-five years ago. Here there can be no question as to the improvement. It is well to remember in this connection that whatever undue prolongation of disease or unnecessary mortality is due to want of skilled medical treatment occurs mainly among the wage-earners—the farmers, mechanics, salesmen, needlewomen, etc.—and not among the rich, nor yet among the very poor.

Now, seeing that really efficacious legislation with regard to medical education or to the practice of medicine must, like all efficacious legislation, be substantially in accord with public opinion, since it is impossible to continue to punish for any length of time that which public opinion does not condemn; and as the great mass of the people of the United States have not as yet had such evidence as they can understand, and which would thoroughly convince them that it is to their interest to suppress quackery, it follows that it is necessary to go slowly and to allow such evidence to accumulate.

To me it seems that the most important of the first steps to be taken in this direction is one which has already been taken in Great Britain—namely, the requirement that every death in the community shall be registered, and that in such registration satisfactory evidence shall be given as to the cause of death, sufficient at least to prove that such cause is what is known as a natural cause, that is, that it is not due to crime. When it is admitted that one of the duties of government is to provide for such registration, both in the interests of life and to secure the rights of property, it follows, necessarily, that those persons whose certificates as to the cause of death are to be accepted as satisfactory evidence that there has been no foul play, must present evidence that they are properly qualified to make such certificates. The principle is precisely the same as that which induces a government to provide for the examination of the medical men whom it employs in its army and navy.

So far as the art of medicine is concerned the demand has much, though by no means all, to do with regulating the quantity and quality of the supply; and there are few localities in the United States where the qualifications of the medical man are not fully up to the standard which the community is able to appreciate and is willing to pay for. In the natural order of things suffering and death are the remedies for ignorance, weakness, and vice, and the means of preventing the transmission of these characteristics to offspring. These remedies, though effectual, are drastic, and we do our best to avoid them, but perhaps it is well that the penalties cannot be done away with altogether.

The laws regulating the practice of medicine in the United States are all State laws. If we were to judge only from what may be found in the statute-books, assuming that all the laws contained therein are duly enforced, we should find that nearly two-thirds of the States have laws ostensibly regulating the practice of medicine within their borders. As a matter of fact, however, in over half the States which have laws on this subject no attempt is made to enforce them, and in almost all of them the possession of a diploma, no matter from what source derived, is all that is required.

Of the various methods which have been tried in different States to insure by law that physicians shall be properly qualified, I will call your attention to two which are of special interest.

The first is that of Alabama, the principle of which is to organize the whole medical profession of the State, and use it as the means of regulating the qualifications of practitioners and of caring for the public health. The Medical Society of the State of Alabama, with its branches the county medical societies, thus forms a part of the machinery of the government; it appoints boards of medical examiners, selects State and county sanitary officials, supervises the registration of vital statistics, the administration of quarantine, etc.—in short, it is the State Board of Health, and the county branches are the county boards of health.

In this State the possession of a diploma does not give the right to practise, it simply enables the owner to go before the examining board. The examinations before the County Board are partly in writing, and are subject to review by the State Board, which has in some instances publicly condemned the local examinations as not sufficient.

This system has now been in operation nine years, and has gradually been consolidated and improved by educating local boards, and getting all physicians interested in it, until it is now working fairly well. Much remains to be done, and it is too soon to predict results; at present the success of the system is largely due to the wisdom and energy of one man, who has given his whole time and labor to the work, and it remains to be seen whether the machine which he has built will work well without him.

The second system to which I will call your attention is that of the State of Illinois, which was commenced in 1877, or about the same time as that of Alabama.

In Illinois anyone who presents a diploma, or license to practise, from a legally chartered medical institution in good standing, is entitled to practise, and the State Board of Health is to decide as to what shall constitute "good standing." The Board of Health also examines all persons who do not possess satisfactory diplomas, and who nevertheless wish to practise in this State.

One of the greatest practical difficulties in the way of providing any system of State examinations in medicine in the United States is that public opinion will not support any law which can be supposed to condemn, or in any way to injure, homœopathic and eclectic practitioners or their schools, and hence any proposed law relating to medicine, or to the organization of State boards of health, which does not recognize the existence of these sects will, in many States, at all events, meet with enough opposition to defeat it. In Illinois this difficulty was surmounted by the arrangement that of the five physicians on the Board, one should be homœopathic and one eclectic. The Kansas law, passed last year, goes further in this direction, and provides that appointments must be so made that no school of medicine shall ever furnish a majority of the members of the Board. Much to the surprise of many, the Illinois plan has worked very well—there has been no quarrelling in the Board—and the homœopathic and eclectic members seem to have upheld quite as high a standard of qualification as their fellow-members. The results of the work in Illinois has been very good. A large number of ignorant charlatans were forced to leave the State.

The requirements of the Board as to what shall constitute a medical college in good standing have been raised, and it has thus caused improvement in the medical schools not only of Illinois but of other States. Moreover, the neighboring States have been stimulated to action, not only by the force of example, but because they received the men who had been driven out of Illinois, and found the accession an unpleasant one.

As in the case of Alabama, it is too soon to judge definitely of the results; and in Illinois, also, the satisfactory working of the system is largely due to one man, the Secretary and executive officer of the Board, who has given his entire time to the work. I do not, by any means, wish you to suppose, however, that I consider this as being a serious objection to this or any other plan, for in the building up of any organization, or the carrying out of any system, much must always depend upon some one man.

The relations of the United States Government to medical education and to the practice of medicine are indirect only, the regulation of these matters by law being part of the police power which, under the Constitution, is reserved exclusively to the individual States. The United States employs physicians in its Indian Department, in the Pension Department, in the Marine Hospital Service, and in the medical departments of the army and navy, and it has power to regulate the practice of medicine in those Territories which are not yet organized into States, and also in the District of Columbia; but thus far it has made no use of such power. The qualifications of physicians employed in the army and navy and in the Marine Hospital Service are determined by examinations made by boards of medical officers belonging to those services. The possession of a diploma from a respectable medical college is a prerequisite for such examination, but beyond this it does not count; that is to say, the examination is the same for the holders of all diplomas, and covers all branches of medicine. But while the relations of the general Government to medical education are thus indirect, they have of late years become of very considerable practical importance, and are now exerting much influence upon medical investigations and literature. This is being effected by the museums and libraries which are now being formed under the auspices of the Government at Washington, and also, to some extent, by certain special investigations undertaken by the Government in the interests of preventive medicine. Of these various agencies one of the most important is the library which has been formed at Washington, under the auspices of the Medical Department of the Army, in connection with the Army Medical Museum, both of these institutions being a part of the results of the late civil war. The museum was at first formed to illustrate military medicine and surgery, giving the results, primary and secondary, of injuries inflicted by modern weapons of warfare, and of the diseases of armies in the field; in which direction the collection is unrivalled in extent and completeness. Gradually its scope has been enlarged to include illustrations of anatomy, development, and all branches of pathology and therapeutics, so that it is fast becoming a museum covering the whole field of medical science. In like manner the library, which commenced in a collection of those books relating solely or especially to military medicine and surgery which were required in the compilation of the "Medical and Surgical History of the War," has expanded into a great medical library, which is now one of the best practical working collections of the kind in the world. These collections, then, no longer appertain exclusively, or chiefly, to the business of one department, but belong to the whole profession of the United States as a body; and the department which has charge of them is managing them from this point of view. The influence of the library in stimulating research, and upon the quality of medical literature, is already very perceptible, and is destined to increase with advancing years. I think I may also venture to claim that the utility of these collections, and especially of the library, is by no means confined to the medical profession of the United States, for the catalogues and indexes which are being issued in connection with them are of service to medical writers and teachers all over the world.

As regards investigations into the causes of disease, undertaken at the expense of the general Government, only a beginning has as yet been made; but it is sufficient to indicate future possibilities and probabilities. The main importance of the work of the National Board of Health, which was organized in 1879 under the stimulus of the great yellow fever epidemic of the previous year, was due to investigations upon the causes of yellow fever and diphtheria, the relations of soils and of water-supply to certain diseases, etc., investigations of the same general character as those which are being prosecuted under the auspices of the Local Government Board in this country, and of the Imperial Board of Health of Germany. It is true that, owing to circumstances which I cannot here explain, the work of the National Board of Health has been stopped; but there is every probability that it will be resumed, with perhaps some change of organization, at no distant day, and I need not dwell upon the vast importance to medical science of organized and systematic work in this direction. Similar investigations have been undertaken by State boards of health, and especially by the State Board of Health of Massachusetts, and the fact that governmental health departments are tending to work in this direction is significant as to future co-operation from such sources.

In this connection should be mentioned the National Museum of Hygiene, which has been formed under the direction of the Medical Department of the United States Navy, which is now one of the most instructive collections of the kind in the world, and has also connected with it an excellent library and a well-equipped laboratory.

Comparative and experimental pathology is also receiving attention from the Government, under the direction of the Department of Agriculture, which is doing some good work in the investigation of the diseases of our domestic animals. Our investigators are, fortunately, not hampered by antivivisection laws, and there is little danger that they ever will be, for though we have our due proportion of fanatics and seekers of notoriety who wish to emulate the British antis, their true motives are so well understood that they have little power to do mischief.

Of medical associations in the United States there are several classes. We have a few local societies, analogous to clubs in their organization, which own property in the form of buildings, libraries, etc., are somewhat conservative in their selection of members, and are only to be found in large cities. Of these the College of Physicians of Philadelphia is the oldest, and has the largest and best library and museum—it will celebrate the hundredth anniversary of its existence next year. In New York the Academy of Medicine, and in Boston the Medical Library Association, are of the same character, and, in general, each large city has a similar society, although as yet they have not become fully anchored and established by the acquisition of property. The second class includes local societies devoted to specialties, such as pathology, obstetrics, etc. These also are found only in large cities, and as yet are few in number. Four of them only have published "Transactions." Corresponding with these are national societies devoted to specialties, such as gynecology, ophthalmology, surgery, pathology, and clinical medicine, etc. These societies meet annually, elect their own members, exercising care in the selection, and publish valuable "Transactions."

Another class is composed of the county medical so-

cieties, which strive to include all regular practitioners residing in their precincts. From these are sent delegates who form the State medical societies and the American Medical Association. The mode of organization varies somewhat in the different States, but the representative principle prevails in all. Most of these societies publish "Transactions;" and the American Medical Association now has its "Journal," and with its work I know that you are all more or less familiar.

As to the condition of medical science and art in America, it partakes of the general progress, for the press now makes all discoveries the common property of the civilized world. The marked feature of the present epoch is the recent advance in knowledge as to the relations between micro-organisms and certain diseases, and the strong stimulus which this has given to preventive medicine. Sanitation is becoming fashionable, and if we may believe some of its votaries, it is a very simple matter to prolong the average lifetime to the scriptural "threescore years and ten." All that is necessary is that everything shall be clean, and every person virtuous.

Having learned to distinguish those diseases which can be prevented much more easily and certainly than they can be cured, we may turn them over to the sanitarian, who has his own battles to fight with ignorance and prejudice. If he succeeds, and so far as he succeeds, he will change, in certain respects, the work of the practitioner.

The lives which are saved from cholera and typhoid, from consumption and diphtheria, and from the acute specific diseases, will, at last, be weakened and destroyed in other ways. The work of the physician will not be lessened by preventive medicine, it will simply be required more for older persons and for another class of diseases. As sanitarians must depend upon practitioners for much of the information which is essential for their work, it follows that if preventive medicine is to become a working power it will bring the mass of the profession into closer relations with the State than its members have held heretofore. What these relations shall be is one of the most interesting, and, at the same time, one of the most difficult, of the many problems with which we, or our successors, must deal. I have referred to some experiments on this subject which are now being tried in America, where it is much easier to make such trials than it is in an older country hampered with vested interests.

Just at present, in this, as in a number of other things, our tendency is toward centralization, both in the several States and for the whole country, and it is not improbable that we may go far on this road in the future.

I come now to the consideration of the second part of my subject, namely, the direction or manner in which we have reason to hope that medicine will be developed in the United States, and the kind of co-operation which you may reasonably expect to receive from the medical profession of that country.

A marked feature of the present day, in medicine as in other things, is the tendency to specialization in study and in practice. But this very development of specialties, of increasing minuteness in the division of labor, increases the necessity for co-operation, and in fact tends to create what we may call the specialty of co-operation. Formerly a rifle, or a watch, was made by a single workman. No two instruments were exactly alike, each piece had its own individuality and was not interchangeable, and the cost of the whole was such as to put it beyond the reach of the multitude. Now, the work on these things is greatly subdivided, one man makes only one small wheel, or spring, or pinion, and another another, each doing his work according to a uniform pattern, rapidly, perfectly, and at comparatively small cost.

But, in addition to the workmen who make the individual parts, it is now necessary to have one person specially skilled in making drawings and preparing patterns, another to assemble the completed parts, and a third to test the whole after it has been put together. As the centrifugal force increases, the centripetal power must also increase.

In one sense medicine as we have it to-day, is the result of co-operation, not of deliberate, centrally planned and direct co-operation, but of natural selection from results produced by many men, often working at cross purposes and, therefore, wasting much energy, but nevertheless working, though blindly, to a common end. And it is safe to predict that in the future much of the best work will be done in the same way, by individual effort inspired by the love of science, by personal ambition, etc. But the results obtained in this way come slowly, and some things that we want can hardly be obtained by individual effort, even if we were willing to wait, hence we must look to organization for help.

This is an age of machinery, of exchanges, of corporations, for all these correspond to one and the same fundamental idea. Men make machines to do what the individual cannot do, and they make them not only of brass and iron, but of men, for such an obvious source of power to the man or men who can master the combination is not likely to be overlooked. One result of such organization is seen in our encyclopedic works on medicine, whether these be called dictionaries or handbooks; another in the great medical journals; another in associations which seek to wield political influence; another in the comparatively recent attempt at collective investigation of disease. With these may be classed also the attempts of government departments to make scientific investigations, to collect libraries and museums, to do things which require long continuity of effort on a definite plan in order to produce the best results.

And it is by the combination of all these, with the efforts of individual workers, that substantial advance and improvement are to be effected.

In this broader view of co-operation it is interesting to consider those fields of labor to which comparatively few physicians can devote themselves, because of want of time and opportunity, but whose proper working is, nevertheless, of the greatest importance to the practitioner.

One of these is experimental laboratory work, and in this direction the prospect of valuable contributions from America is now exceedingly good. Some of the wisest of our most wealthy men have shown their appreciation of the responsibilities which riches entail on their possessors by seeking new channels through which to benefit their fellow-men. While the old and well-known methods of endowing hospitals and charitable institutions are not neglected, there is apparent an increasing tendency to endeavor to promote the advancement of knowledge, and especially of such knowledge as tends to the mitigation of suffering and the improvement of the race, to furnish means for the investigation of disease, to provide laboratories, and to endow medical schools, and thus place them beyond the reach of the temptations and difficulties which must always exist when such schools are dependent upon the fees of students, and are, therefore, practically, commercial manufacturing establishments.

As illustrations of this tendency I may mention the bequest of £1,400,000 by Johns Hopkins to endow, in the city of Baltimore, a university and a hospital, of which the medical department is to be a special feature, to be provided with the best laboratory and other facilities for original investigation as well as for teaching; the gift of Mr. Carnegie to the Bellevue Hospital Medical School of New York, in the shape of a well-equipped pathological laboratory; the presentation by Mr. Vanderbilt, and members of his family, to the College of Physicians of New York, of £200,000, to provide for that school new buildings and clinics having the best means of teaching and research, and the endowment, by an unknown donor, of a laboratory for the University Medical College of New York with the sum of £20,000.

Last year, in his retiring address as President of the New York Academy of Medicine, Dr. Loomis referred to this tendency to regard wealth as a trust to be used for the benefit of humanity, and after sketching the requirements of the Academy on a scale which would require an endowment of at least a million of dollars, predicted that such an endowment would be furnished by wealthy citizens of the city. I believe that he was right, and that his prediction will become history.

As the class of men who have wealth, leisure, and knowledge becomes greater, there comes an ever-increasing demand, not only for the best medical skill, for the most expert practitioner, but also for exhaustive research in every direction which promises to furnish new means for the prevention or relief of suffering, and for warding off, as long as possible, the inevitable end; and hence there is little reason to doubt that the examples I have named will be followed by others in the near future. With such opportunities, and under such conditions and influences, the stimulus to the young and ambitious worker is strong; we have abundance of material of this kind upon which the process of natural selection can operate, and there is little reason to doubt that the result will be substantial and valuable contributions to physiology, pathology, and therapeutics.

I have already referred to some of the work which has been undertaken by the United States Government for the benefit of medicine and of the medical profession in the formation of a library and the providing of means of assistance in bibliographical research. There is another most important means of advancing medical and sanitary science which only a Government can furnish, and in which field of work England now stands pre-eminent—I refer to vital statistics. In this field the United States Government has thus far done but little, yet enough to show the great interest and value of what we have a right to hope will be done in the future by combining the work of the several States. This is one of the fields in which international co-operation is most desirable; it alone can furnish data sufficiently complete and reliable for a scientific consideration of the relations of disease to geographical and race distinctions.

Geographical pathology is a very old branch of medicine, as old, at least, as Hippocrates, whose treatise on airs, waters, and places is justly famous. Permit me to remind you of its opening clauses. "Whoever wishes to investigate medicine properly should proceed to consider the seasons of the year and what effects each of them produces, the winds, the qualities of the waters, the situation and exposure of the city, the character of the ground, and the mode of life of the inhabitants." Then, says the wise old Greek, "From these things he must proceed to investigate everything else."

There is a breadth of view in that last sentence which is particularly satisfactory. Since the days of Hippocrates there has accumulated a vast amount of literature relating to the supposed connection between the topographical peculiarities of different cities and countries, and the diseases which prevail in them; but when the books and essays which come under the heading of "Medical Topography" are examined it will be found that the topographical part is much more complete than the medical—which last is mainly confined to the consideration of malarial diseases, and is vague and indefinite with regard to their relative prevalence.

Much the larger part of our really valuable information on this subject has been obtained within the last twenty-five years, as Professor Hirsch points out in the preface to the recent edition of his very valuable "Handbook of Geographical and Historical Pathology," and while the contributions of the United States to this branch of medical science have been already important, I hope to be able to show you that they are probably destined to be of steadily increasing importance in the future. Considered as a body the opportunities of the medical profession of the United States for the study of the manifold influences which can cause, modify, or prevent disease,

are in some respects unequalled. As regards peculiarities of climate, soil, altitude, etc., the country is so large as to afford almost every variety of combination, so that nature may be said to be making a series of experiments, on a grand scale, upon the mass of humanity which is so rapidly increasing in the new world. Especially is this the case with regard to the problems of heredity as connected with the mysterious relations of certain forms of disease to race. America is at present the great mixing-bowl into which are pouring streams of human life from origins the most diverse, from regions the most remote. Black and white, red and yellow, long skulls and short skulls, Celt, Teuton, and Slav are being brought together under similar conditions of climate, food, and occupation, thus permitting of the comparison and study of the different effects, if such exist, which result from variations in parentage under conditions of exposure to the same causes of disease.

For a little time—a generation or two at least—the different streams remain pure, then there is more or less mingling, in some cases very little, in others very intimate, but always there is an opportunity for studying the races separately, as well as of investigating the results of their various mixtures.

To illustrate the possibilities in this direction I will call your attention to some peculiarities in the distribution of deaths from certain causes in different parts of the United States, and for this purpose I shall make use of the data from our last census, taken in 1880. We have no general and uniform system of registration of births and deaths. The larger cities and about half a dozen States have such a system; but for much the larger portion of the country the only means which we have for determining differences in amount or causes of mortality in different localities is through the census, which is taken once in ten years. The data thus obtained with regard to deaths are imperfect, because when these are collected, only at the end of the year, about thirty per cent. of the deaths are unrecorded; and they are inaccurate, because the reports of the causes of death are not furnished by persons competent to give reliable information with regard to them. Nevertheless, these data are the best that we have, and although for a large part of the country they do not give us the actual number of deaths from any cause or set of causes, they do furnish some interesting information with regard to the relative prevalence and importance of certain causes, and suggest questions and lines for future investigation, although they do not furnish definite and scientific answers.

Take, for instance, this map of the United States (Chart II.), upon which, by varying shades of color, is shown the proportion of deaths reported as due to cancer, as compared with the reported deaths from all causes. Cancer, using the term in its broadest sense, is a disease which seems to be gradually increasing in frequency among civilized nations, and, possibly, to have a tendency to increase with the advance of civilization.

In England and Wales the proportion of deaths from this cause seems to have nearly doubled within the last twenty-six years, and a similar rate of increase can be made out in certain parts of America. How far this increase is a real one, and how far it is due simply to improvement in diagnosis, is a question yet unanswered.

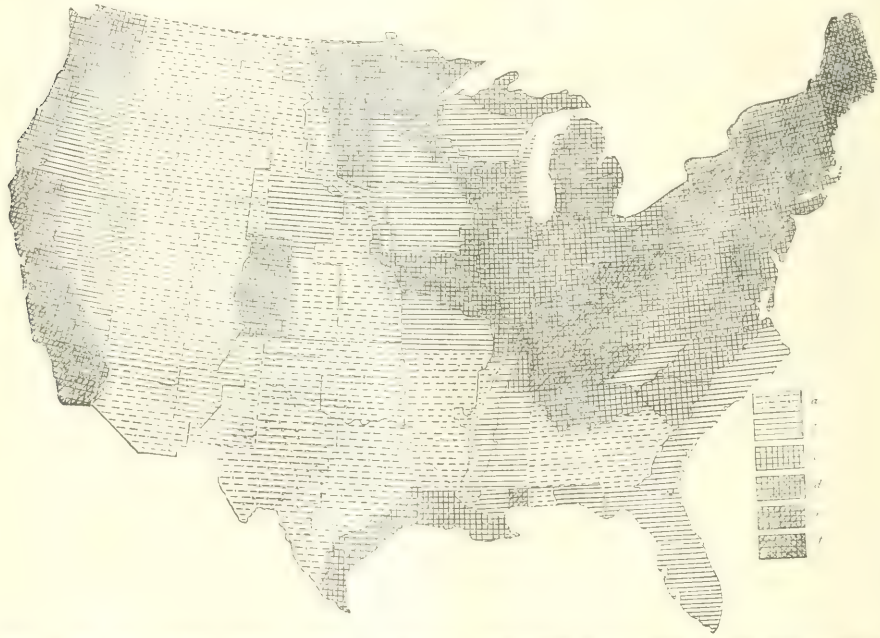

CHART III.—Map of the United States, showing the distribution [illegible] from consumption [illegible] compared with total deaths from known causes, Census of 1880.
a. Under [illegible] per 1,000. b. [illegible] per 1,000. c. [illegible] per 1,000. d. 12 and [illegible] per 1,000. e. [illegible] per 1,000. f. 17.5 and over per 1,000.

The mortality from cancer in the United States is proportionately greatest in the New England States, somewhat less so in New York and Pennsylvania, and it causes the least proportion of deaths in the Mississippi Valley and the South generally. The proportion of deaths from cancer in the United States is somewhat greater than it is in England; but it is not possible to make any accurate comparisons in this respect. Now why are the shades on this map so dark on the Northeast and so light in the South? In the first place, cancer is a disease the mortality from which steadily increases with advanced age, as you may see from this diagram. Hence, cancer causes a higher proportion of mortality in those localities which have the greatest proportion of population living at advanced ages, and in the United States

these localities are the New England States, as you will see by this map. One deduction from this, which may perhaps not have occurred to all of you, is that a large proportion of deaths from cancer indicates, to a certain extent, that the locality in which it occurs is a healthy and long-settled one, since it has probably a relatively large proportion of inhabitants, and especially females, of an advanced age. But another explanation of the peculiar shading of the cancer map is found in the relations of race to the tendency to death from this disease. The proportion of annual deaths from cancer per hundred thousand living population was, in round numbers, twenty-eight for the whites, and thirteen for the colored. That is to say, cancer is more than twice as prevalent among whites as it is among colored in the same localities, for these figures apply only to the South. On the other hand, cancer appears to cause a greater proportion of deaths in persons of Irish and German parentage than it does among the rest of the white population, the indications being that between the ages of fifteen and sixty-five the Germans are especially liable to cancer; more so than the Irish, and decidedly more so than the average white population. Now when we remember that the greater part of the colored population is in the South, and the greater part of the Irish and German population is in the North, we have another reason for the differences in mortality caused by this disease in the two sections.

Again, take this map, showing the distribution of the deaths from scarlet fever during the census year. You see that this also was most fatal in the North, and here again the influence of race comes in, because in the negro race the mortality from this disease appears to be very low. This disease has always been much rarer in the South than in the North, and the contrast was much stronger in former years than it is at present; but this cannot be explained solely, or even to any great extent, by difference of temperature, because scarlet fever has often been epidemic in the tropics, and, on the other hand, in many localities in temperate climates it is among the rarest of diseases.

Here is another map, showing the distribution of deaths reported as due to diphtheria during the year. Diphtheria is a disease which has been unusually prevalent in the northern portion of the United States for several years. During the census year it causes 2,374 deaths out of every 100,000 deaths from all causes, while in England, for the year 1880, the deaths from diphtheria were 532 per 100,000 deaths from all causes; that is to say, the comparative mortality from this disease in England was less than one-fourth that of the United States for the same period. Diphtheria, again, is essentially a disease of the North, but especially of the Northwest. It causes an excessive mortality in children of German parentage, sufficiently so to show that here again the influence of race comes into the problem, although, probably, only indirectly; that is to say, it is probable that it is the habits of a peculiar class of people which

Chart IV. Map of the United States [illegible]

favors the propagation of the disease rather than any physical peculiarities in the structure of their bodies.

Two more illustrations of the geographical distribution of disease in the United States may be of interest in this connection. The first is that of consumption, the second, of pneumonia.

Consumption is a vague term, and as used in the census no doubt includes many cases which were not true tubercular phthisis. It is reported as causing twelve per cent. of all the deaths, or more than any other single cause. In England and Wales, in 1880, it caused a little over nine per cent. of all the deaths. Such wholesale ratios are, however, of little interest or value. There are very great differences in the liability to this disease in different parts of the United States, as the map makes sufficiently evident, and it is from a study of the causes of these differences in the data derived from large masses of people, combined with clinical histories and experimental laboratory work, that we have good reason to hope to obtain knowledge, not only of the causes of

this disease, but of better methods of prevention and treatment than are now at our command. It causes a greater mortality among the Irish than in other white races, and, perhaps, a greater mortality among the colored than among the white.

Next to consumption, pneumonia is reported as causing the greatest number of deaths in the United States during the census year, giving a ratio of 8.3 per cent. of all deaths, as against 4.8 per cent. in England and Wales in 1880. Here, again, the local distribution of deaths is interesting, and the contrast between the map of consumption and that of pneumonia is very striking. Here, again, we find that race peculiarity is an important factor in the problem, the proportion of deaths from pneumonia among the colored being much greater than it is among the white.

I have elsewhere commented more fully than it is possible to do here upon these peculiarities of the distribution of certain causes of deaths in the United States.[1] In fact, my only object in calling your attention to the subject is to indicate the direction in which we may hope for good work hereafter, which indication is the chief, if not the only valuable result of the work already done. In the brief comments which I have made upon these maps you will have noticed the stress which I have laid upon race peculiarities. These race problems are simply problems of heredity taken in mass, and there is no need to urge upon an assemblage of medical practitioners the importance of considering family peculiarities in diagnosis, prognosis, and therapeutics. That the questions involved are difficult and complicated is true, but we are already possessed of more knowledge with regard to them than is commonly supposed.

In a lecture on "Life," delivered a few months ago, Professor Brookes, of the Johns Hopkins University, illustrated this as follows: "If I am placed, with my eyes bandaged, before a stone lying free on the surface and am told to kick it, and if I know at the same time the size, shape, and weight of the stone and the character of the surface, I can form a pretty accurate idea as to what the result upon the stone will be. While if the object to be kicked is a dog, and I am given precisely the same data, I cannot tell what will be the effect. But if I can see the dog, I can, in many cases, predict pretty accurately. If he is a bulldog, he will do one thing; if he is a Gordon setter, he will do another." And, in like manner, the old family doctor knows that when a particular disease appears in his neighborhood, he may expect to see it produce in one family convulsions, in another collapse, and, in a third, little or no danger or inconvenience.

This kind of knowledge is, however, at present mainly confined to individuals, it has not become a part of the world's knowledge; it is not defined; in other words, it is not scientific. To make it so is the work of the future, and in this work I hope that we shall be able to help you.

I have spoken to little purpose if I have failed to show you that there is a great deal of human nature in American physicians, and it is a kind of human nature with which you are tolerably familiar. It should be so, for we are of the same race—a race which, perhaps, as Emerson says, "sets a higher value on wealth, victory, and material superiority than other men, has less tranquillity, is less easily contented." Our ancestors were restless, fighters, freebooters, and from these ancestors we have the common inheritance of energy; of what *we* call "firmness," and our opponents unreasonable pigheaded stubbornness; of liking to manage our own affairs, and, at the same time, to exercise a little judicious supervision over those of our neighbors; of hatred of humbug and lying; and, in spite of our discontent, of a firm belief that our wives and children, habits, houses, modes of business, and of treating disease are, on the whole, better than those of any other people under the sun.

Privately, and between ourselves, we grumble and declare that the country and profession are going to the dogs—nay, we must do so, or we should not be of true English blood; but there is no need for me to tell you that these are only "growing pains," and not symptoms of progressive ataxy.

While we must consider the difficulties in the way of the improvement of the science and art of medicine, difficulties due to ignorance, to indolence, to conflict of interests, and to the eternal fitness of things, the existence of such difficulties is not a matter to be bemoaned and lamented over. These obstacles are the spice of life, the incentives to action, the source of some of the greatest pleasures which it is given to man to experience.

The child spending a happy hour with its new puzzle is a type of the scientific investigator. The naturalist who objected to the statement that this is a miserable world which it is well to be soon done with, on the ground that there are still many species of rhizopods which he had not examined and classified, is another type. On the ethical and sociological side the matter is summed up in Ruskin's aphorism, that "Fools were made that wise men may take care of them."

It is surely not without cause that there has been given to us this restless spirit of inquisitiveness, this desire to compass the heavens and the earth, this raging, infinite thirst for knowledge—it is the outcome of brain-training and natural selection for thousands and tens of thousands of years.

We are in a period of the world's history characterized by material prosperity, by increase of populations, by tendencies to uniformity, to the making of individuals of small account. According to the Swiss philosopher, Alphonse de Candolle, this is to last a thousand years or so, after which the pendulum will swing the other way, and there will follow a long period of diminution and separation of peoples, and of decadence.

Against that decay of nations we know of but one remedy, and that is increase of knowledge and of wisdom. And this increase must be in *our* knowledge, in the world's wisdom, and not merely in that of John, or Fritz, or Claude.

As each man has special opportunities and duties, if he can only recognize them, so it is with guilds, with professions, and with nations.

I have tried to indicate to you some of these opportunities which are presenting themselves to my colleagues, your brothers, in the lands beyond the sea, and I hope that I shall not be considered rash or vainglorious in saying that I believe they will so use those opportunities as to return compound interest for what they have received from the storehouse of our common inheritance. Force changes form and place, the stored energy of the soil of our plains and valleys has been coming here in the form of meat and grain, has appeared in muscle and brain and in a hundred other shapes, but none has been destroyed; our loss has been your gain, and in our turn we have received full and fair exchange.

It is our part now to remember that there are not two springs in the year, there are not two periods of youth abounding in energy and desire, or of manhood's strength and self-poise, in the life of any man or of any nation, and for us, as for those who have been before us, the Kanuri proverb holds true, "*Kaïa kitsia, tirgum kaze*"—The days being finished, there is no more medicine.

[illegible]

Sure Cure for Corns.—A man in Geneva advertised a certain cure for corns, full directions to be sent on receipt of one mark. Those who inclosed the proper amount received by return mail some doggerel verses advising amputation as an infallible preventive of further discomfort.

SOME POINTS IN UTERINE PATHOLOGY.

By J. C. OLIVER, M.D.,

THERE still appears to be a considerable amount of mystery connected with uterine pathology, in spite of all that has been done to elucidate this subject. Each gynecologist is expected to have his own theory concerning the causes of uterine displacements and the manner in which they operate. Each physician who claims any eminence in this specialty is expected to invent a pessary, forceps, or speculum, which he considers far superior to any other.

With these facts borne well in mind, we still have the temerity to advance a theory as to the causes of uterine displacements. We have been impressed with the fact that gynecologists have written all around this theory, but none whom we have read have distinctly and clearly pointed out what we shall endeavor to explain.

Professor Huxley points out the fact that nearly one-half the weight of the body is supplied by the muscles and their appurtenances. We are told that about one-fourth of the blood in the body is sent to the muscles, and also about one-fourth passes through the liver, and it is in these parts that the greatest changes in the blood takes place (Foster's "Physiology," p. 40).

A fact that has been almost universally received is that the uterus and appendages are very prone to congestion, mostly passive in its character. We propose going a little further back to inquire into the causes producing congestion. In order to accomplish anything in that line we shall have occasion to scrutinize the local conditions, and also conditions remote from the uterus.

The position we take upon this subject is, that the deficient development of muscular tissue and power among our females is the great underlying cause of uterine diseases of an inflammatory or mechanical nature.

As we have had occasion to mention previously, the congestion is venous or passive in its nature, and is due to some interference to the return flow of the blood, either located within the uterus or between the uterus and the heart.

It seems to me that the early life and habits of our girls is specially adapted to the production of troubles in after life. From their earliest years in life a large majority of our girls have a very strong prejudice against exercise in mostly any form. They prefer riding to walking; they do dance some; but so far as good, general muscular exercise is concerned, they never know exactly what it means. As a consequence of this life of inactivity and muscular idleness, the muscular tone of the entire system is very much lowered and impaired. Less blood than its fair proportion is sent to the muscular apparatus, and consequently any little exercise wearies them.

These pelvic derangements are not confined solely to the female portion of our community, but males suffer with what, to my mind, are similar conditions. Men leading a sedentary life, without the opportunity or inclination to exercise their muscles, are very subject, as we all know, to hæmorrhoids, constipation, etc.

The returning blood from the uterus and appendages passes through the pampiniform plexus, and thence to the inferior vena cava. A fact in regard to the anatomical peculiarities of these veins that should be borne in mind is that they are not supplied with valves, and consequently a backward pressure in these parts is encouraged. If the muscles are not active, the blood going to them is lessened in proportion to their inactivity; hence the blood that should be sent to the muscles must find its way into other channels. As it cannot be sent to the vascular apparatus, it must be sent in excess to the viscera. Now this excess of blood causes a congestion, and as the same conditions remain operative, the congestion becomes chronic in character, and thus we have developed hæmorrhoids, constipation, and uterine disorders.

This muscular atony produces another condition favorable to the development of [illegible], namely, the retentive powers of the abdominal muscles are impaired, and instead of having a firm, elastic, contractile abdominal wall, we have a weak and flabby tissue which scarcely deserves the name of muscle. After the distention of these walls by pregnancy they become still more relaxed, and never return to anything like the muscular tissue we might reasonably expect to find in that locality. I think we shall agree that this is a very important factor in the production of the conditions under consideration.

Another point that should not be overlooked in this connection is the very common union of bilious troubles with menorrhagia, hæmorrhoids, etc. We do not hold that these conditions are the cause of uterine troubles, but that they are produced by exactly the same cause that determines the disease above mentioned, namely, muscular atony. J. Milner Fothergill, M.D., in his book entitled "Diseases of Sedentary and Advanced Life," says: "Behind the liver lies the whole network of the portal venous system, with its myriads of venules, many of which inosculate with the branches belonging to the internal iliac vein. The uterine arteries are tortuous, and share in that capacity for adaptation for change of form, involving elongation, which is requisite for uterine growth in pregnancy. The arteries then are tortuous, while the vascular supply is, as a whole, large. The veins, too, are tortuous, and inosculate with each other freely. Consequently any interference with the blood-flow through the liver would react backward upon the whole vascular network of the pelvis, including alike the uterine plexuses and the hæmorrhoidal veins. From this would follow congestion of the whole area, alike of the uterus and the mucous lining of the bowel. The swollen veins of the mucous lining of the reproductive organs and the engorged uterine sinuses would set up both the excessive flow at the menstrual period and the leucorrhœa found during the interval. The venous turgescence of the rectal lining membrane would give either hæmorrhoids or a relaxed state of the rectal wall, which would either lead to prolapsus or produce folds of relaxed mucous membrane requiring removal by the knife. The addition of loaded bowels to this interrupted flow of venous blood would aggravate the condition" (pp. 45 and 46).

This hypothesis receives still further support from the fact that our muscular women are much less liable to uterine troubles than our less muscular, and consequently weaker, sisters. This is exemplified further by the fact that men who resort to active muscular exercise (I do not mean professional athletes) do not suffer from piles and other pelvic and intestinal disorders. Another statement from the authority above quoted is worthy of repetition: "The proportion of female troubles in England as compared to the United States is probably in inverse proportion to the extent of walking exercise taken by the females of the two countries. In America the ladies walk little, and uterine troubles are excessively common there; while in England the appeal to the gynecologist is much less common, especially among women who are much on their legs out-of-doors." We also would like to present the following sentence from the same book: "When the intrapelvic muscles are round and full there is little risk of uterine displacement."

We are told by physiologists that muscular action is one of the principal (if not the principal) causes of flow of blood in the veins. Another cause is the suction-force exerted by the thorax in respiration. These causes are possibly assisted by a contraction of the walls of the vessels themselves. This last force must of necessity be very limited in its action. The blood from all the viscera is, as we have seen, sluggish in its movement, and so there must exist a passive congestion of these parts. If any proof for this last statement is needed, it is furnished by the abdominal symptoms presented in these very

cases. Such women are almost invariably constipated, lack color in their faces, the tongue is coated more or less heavily, their minds are not capable of fixed attention for any length of time, they are easily depressed, and so we might enumerate a long list of symptoms referable to the condition of the abdominal and pelvic viscera.

With this condition as a starting point, we can readily see how the ordinarily accepted causes may occur and act as exciting causes. This hypothesis explains the reason of so frequent congestions of the uterus, lack of tone of uterine ligaments, weakening of natural supports of the uterus, and other causes "too numerous to mention."

As has been mentioned before, the suction-force exerted by respiration is a considerable factor in the production of venous circulation. This important function is more or less embarrassed by the use of corsets among the female population. This same article of dress interferes with the free action of the muscles of the trunk, chest, and diaphragm, and presses the abdominal contents downward toward the pelvic cavity, and thus becomes a factor in the production of displacements. Were the muscular system in better condition this factor would, in our opinion, become much less important in its bearings.

It is always admissible, in discussions of this character, to adduce therapeutic measures to support one's position, and, with this purpose in view, we wish to call attention for a short time to the action of massage in the treatment of this class of disorders. It has been demonstrated that massage of a muscle increases its resistance to the fatigue of exercise, and rapidly restores the muscle to a condition in which it can undergo even greater functional activity than it could primarily (Brunton's "Therapeutics," p. 128). He says: "Massage has a similar action to a very complete and perfect circulation through the muscle, in removing the waste products and restoring its power."

Now, if what has been said so far is true, what is the rational, and at the same time the most promising, plan of treatment to be adopted in these cases? Does it appear rational to use pessaries to support the uterus? Do pessaries ever cure a displaced uterus? Do we increase the power of a muscular organ by using splints? Is the substitution of an artificial for a natural support beneficial? It is claimed by some that the vagina acts as a support for the uterus; this statement is open to considerable doubt, but if we grant the truth of the assertion, why impair the elasticity of the vagina by the use of a pessary? The pessary, in order to be at all efficient, must have some other point of support than the vaginal wall, and the only available structures for such purposes are the bones of the pelvis. If the ends of the pessary rest upon the pelvic walls, they must produce a distention of the vagina, and will not this constant distention produce a lack of resiliency of the vagina?

The pessary is a foreign body, and the animal nature abhors a foreign body. This foreign body will, of necessity, cause an irritation or keep up an already existing irritation. Irritation produces congestion. Congestion produces hypersecretion; and thus we cause or assist the very condition we are striving to combat. These statements are incontrovertible, for who of us has not seen the irritation and ulceration produced solely by a pessary?

Professor Thomas, on page 401 of his work on gynecology, says: "The desideratum is an instrument which will not distend the vagina at the same time that it will support the uterus. Such instruments as sustain the vagina without distending it, and thus allow it to regain something of its former tone and elasticity, are those which should be, as far as possible, selected." We agree with these sentiments, but ask where shall we find such a pessary? The vagina is a closed canal, and any pessary must of necessity interfere with the natural arrangement of the parts.

As has been mentioned, the pessary must have a point of resistance in order to be at all effective, and the object of pressure below the uterus is to combat pressure from above; and by this means we have two forces opposed to each other, with the uterus as the central point. What could be a more certain way of producing a bending of the uterus than these very means? When it is borne in mind that the uterus is not a solid body, this action and reaction assume very respectable proportions. If it were a solid body, it would of course pass in the direction of least resistance.

The secretions from the uterus and vagina adhere to the pessary, and sooner or later undergo decomposition, and were the mere presence of a foreign body not sufficient to produce irritation, we have the presence of this decomposing secretion ready to turn the scale in favor of irritation.

Other objections may be urged against the use of pessaries, such as pressure upon the rectum, the mental concentration of the individual upon her generative organs, the liability of pessaries to change their position, the weakening of natural supports from enforced inactivity, etc.

Dr. E. C. Dudley says: "The various anteflexion and anteversion pessaries which have been devised for the purpose of propping up the corpus are almost useless. Their false reputation depends upon the relief which they frequently give to complicating prolapse, the symptoms of which have been wrongly attributed to anteversion and flexion" (Pepper's "System of Medicine," vol. iv., p. 181).

J. Mathews Duncan says: "Now, in the present great abundance of contorted bits of wood, metal, and vulcanite, and what not, called pessaries, my advice to you is Punch's advice to a young man contemplating marriage —'Don't.'" Further along in the same lecture he says: "They (pessaries) are always harborers of dirt, and always keep the mind watching the part. They are liable to decay, and if long used require to be renewed."

In the same article he says: "As a matter of fact, I find the majority of versions and flexions, as observed in practice and treated by pessaries, have their whole condition of displacement quite unaltered by the pessaries, even while in" (*British Times and Gazette*, vol. ii., pp. 769, 770. 1882).

The important question arises in all these cases, as to whether the uterine displacement is a primary condition or whether it is the secondary manifestation of a weakened and debilitated state of the general health. Whether, in other words, the general health is not so far deteriorated that any exciting cause of disease may serve to light up a condition which would never occur were the woman's constitutional condition good.

Pregnancy, as we all know, leaves many of our women with subinvolution, displacements, etc. This should not occur, according to physiological laws, and occurs but seldom in those women who are well developed muscularly.

With these facts borne in mind, it appears perfectly rational to direct our primary treatment to the constitutional condition, and consider the uterine displacements as entirely secondary in their importance.

The plan of treatment should assume about the following order: 1, Build up the general health; 2, increase the quality of the blood; 3, restore the retentive power of the abdomen; 4, divert blood to other parts than the generative tract; 5, increase the thoracic cavity; 6, increase tonicity of natural supports; 7, regulate the action of the bowels; and 8, remedy the displacement, if any exists at this time.

It has been demonstrated that the uterine ligaments contain muscular fibres, and muscular fibres, in order to be effective, should be possessed of good tonicity, and this tonicity is not present if the general muscular system is degenerated.

In these conditions, as in all diseases, we should first direct our attention to a prophylactic treatment. If our young girls were taught to exercise systematically in their

youth—to bring their muscular system up to as good a standard as boys of the same age possess; if they were taught that exercise is not unbecoming a lady; if they were given proper and systematic exercise, instead of being cooped up in a dark, illy-ventilated school-room for six hours, and given lessons sufficient to occupy their minds for six hours more—rendering it almost impossible to obtain time for exercise, we might have a race of girls of whom we could justly feel proud.

In our opinion the school-life of our girls sows the seed for many of the uterine diseases which make their appearance later in life. None of us can shut his eyes to the harvest that is reaped.

Would not the above-mentioned mode of procedure be of great service in building up the general health; in increasing the quantity and quality of the blood; in giving a good retentive power to the abdomen; in diverting blood to other parts; in enlarging the cavity of the chest; in adding tone to the natural supports; and will it not keep the bowels open, and all the secretions in a normal condition? The exercise will certainly improve the appetite and digestion, and must improve and increase nutrition. A large number of additional facts could be adduced in support of these opinions, but enough has been said to indicate their importance.

But we, as physicians, are seldom called upon before actual disease is present, and all the disagreeable symptoms and conditions are in actual operation. We are now called upon to remedy conditions which are the result of preceding negligence and apathy. Our present methods of treating these cases are notoriously inefficient, and are merely palliative. We seldom cure a case of uterine displacement.

The solution of this problem appears to lie in a judicious combination of massage, electricity, and active exercise. The results that have been obtained by massage certainly eclipse any successes by other methods. These results are, for the most part, permanent, and have the additional recommendation of being along the line indicated by nature.

In very many of these cases active exercise would be impracticable, as any exercise tires the patient, and they sooner or later seek comfort by remaining in bed all the time. They thus become confirmed invalids, solely due to a lack of vital force, and of necessity the energy is lacking.

For these confirmed invalids active exercise seems to be strongly contraindicated as a primary therapeutic measure; but not so with massage, for it is with this very class of cases that Weir Mitchell achieves such signal success. After a course of massage we think that active exercise might be used successfully to retain, and even improve upon the benefit obtained from massage; for it has been shown that massage of a muscle increases its resistance to the fatigue of exercise, and rapidly restores it to a condition in which it can undergo even greater functional activity than it could primarily. Brunton, upon page 128 of his work upon "Therapeutics," says: "Massage has a similar action to a very complete and perfect circulation through the muscle in removing the waste-products and restoring its power."

By means of exercise we increase the number and depth of respiratory movements, and also tend to enlarge the chest cavity, and it naturally follows that the suction-power of respiration is increased.

Douglas Graham, in his "Practical Treatise on Massage," points out the fact that the respiratory movements produce a sort of massage of the abdominal and pelvic organs by the to and fro movements of the diaphragm. Of course any increased activity and capability of the diaphragm would enhance its beneficial results upon these viscera.

This does not by any means exhaust what could be said upon this subject, but enough has been said, I think, to clearly prove that this method of treatment far outrivals anything we may expect from the use of pessaries, local applications, and tonic medicines. Of course the physician is called upon to make greater efforts, and to devote more time and attention to these cases than he does at present; but the knowledge of a work well done should be sufficient incentive to urge him to adopt those methods best calculated to give patients comfort and lasting relief.

As regards the permanency of cure, I cannot do better than to refer to the tables given by Douglas Graham, and collected from various sources. These results are certainly a great deal better than our usual results, and appear to give promise of permanent relief in a great many cases of uterine disease.

Dr. Weir Mitchell, in his book entitled "Fat and Blood," says: "I have been lately at some pains to learn the fate of many of my earlier cases, and can say with certainty that every case then treated was selected because all else had failed, and I find that relapses into the state they were in when brought to me have been very uncommon. A vast proportion have remained in useful health, and a small number have lost a part of their gains" (pages 161, 162).

EMBOLISM OF THE MEDULLA.

BY GEORGE A. SWASEY, M.D.

I THINK the following case presents clinical features of sufficient interest to warrant me in preparing a brief report of it. Cases of embolism and thrombosis of the medulla were once considered to be of exceedingly rare occurrence; but of late years quite a goodly number have been reported, and by recent writers they are referred to as not being so very uncommon. Cases which were formerly diagnosed as apoplexy of the medulla are now known to have been—some of them, at least—cases in which an obstruction had occurred at some point in one or more of the main arteries supplying this important nerve-centre. Duret, writing in 1873, clearly set forth the more important symptoms characteristic of these affections, and did much to elucidate the anatomy and physiology of the medulla, thereby rendering it more nearly possible to localize a lesion when once it had occurred. Later Duffin, Eichhorst, Lichtheim, Hurst, Senator, and others have either reported cases of embolism or thrombosis, or have contributed essays upon the subject.

The following case I saw, with Dr. C. D. Smith, of this city, in April, 1885: James D——, Irish, waiter, aged thirty-two, single. For several weeks previous to the present illness he had been out of employment, and for a month previous had been drinking freely; states that he had a chancre three years ago; family history unimportant. Upon April 9th he had used liquor, but went to bed that evening feeling as well as usual, and slept well through the night. Upon waking on the morning of the 10th he had lost the power of speech, was unable to swallow, and suffered pain in the region of the sternum. When walking he was dizzy, and staggered; complained of a ringing sound in his right ear; urine passed normally; bowels constipated. These constituted the symptoms upon the morning of the 10th, so far as they could be ascertained from the patient and his mother.

I saw the patient on the afternoon of the 10th. He was a short, "thick-set" man, with full face, which was somewhat flushed, and the eyes were injected, as is so common after hard drinking; pulse, 108, the calibre of the artery appearing small; temperature under tongue, $99\frac{4}{10}$° F.; heart and lungs normal; urine not examined at this time.

He walked slowly and somewhat hesitatingly, which was due to paresis of the lower extremities, and this was most marked upon the right side.

With eyes closed he could walk quite well, and could stand with his heels together without reeling. He was

able also to stand upon one foot, with eyes closed, but with much difficulty upon the right, owing to its weakened condition.

The power of flexion and extension of the leg upon the thigh was reduced upon both sides, the muscles of the right thigh being weaker than those of the left. Both upper extremities were paretic; but the degree to which muscular power was reduced was not accurately determined until a day or two later. The mind was clear, and had been since he awoke in the morning. He readily understood all that was said to him, and would try very hard to reply to questions; but the function of articulate speech was completely lost—aphonia paralytica. The patient was unable to swallow, the liquids flowing out of the mouth and into the larynx. Cough was thus excited, but not so readily as in health. I believe the laryngeal mucous membrane was anæsthetic. He could open his mouth about one-half the normal distance, but was unable to protrude the tongue, it remaining motionless in the floor of the mouth. The palatine arch was lessened, but symmetrical, and the mucous membrane covering it and the pharynx was anæsthetic. The facial nerve upon the right side was paretic, which was most marked in its lower fibres of distribution, the orbicularis oculi upon this side closing slowly, and the mouth was drawn somewhat to the left. The lower fibres of distribution of the left facial were paretic, but to a less degree than those of the right, the orbicularis oculi closing normally. The respirations were 22, slightly Cheyne-Stokes in character, and he would often gape, which would be full and prolonged. The pupils were somewhat dilated, contracting slowly to the light. Vision was not tested; but there was no complaint of its failure at the time, nor has there been since. There was a ringing sound in the right ear, and the hearing on this side was lessened.

The patient was put to bed and fed with milk by the stomach-tube. Bowels were opened with croton-oil, which was added to the milk. Milk was also given by the bowel, to which was added ext. ergot. and sod. brom.

April 16th.—Temperature, 98⅔°; pulse, 94; respirations, 16, at times stertorous. He still gapes a good deal, but somewhat less than for the past two days. The urine has been examined and found to contain neither albumen nor sugar. At this time the loss of muscular power in the forearms was more definitely noted. With the left hand he drove the needle of the dynamometer to 26°, and with the right to 20°. With my own hands I drive it to 110° with the right, and to 100° with the left. In persons in health whom I have tested I have found a difference of about ten degrees in the two hands. This patient was right-handed, and, while the muscular power was much reduced in both arms, that of the right showed a paretic condition greater than that of the left by 16°, assuming the above estimate as a standard.

The plantar reflexes were lessened. The left cremasteric was lessened, the right absent; abdominal absent; other (superficial) reflexes not tested; patellar-tendon reflexes exaggerated; left ulnar and radial reflexes present, right absent. Tactile sensibility: Right calf, 8°; left calf, 8°; back of right hand, 2°; back of left hand, $5\frac{6}{10}$°; right cheek, $1\frac{8}{10}$°; left, 7°. Sensibility to faradic current about normal; bladder normal; bowels constipated.

May 15th.—Improvement has been uninterrupted, so that now he can swallow quite well.

Says "ya" for yes, and while he can pronounce some words he cannot carry on conversation.

The paretic condition of the extremities has quite disappeared, the general sensibility has improved, and he can protrude the tongue a short distance.

June 15th.—Patient has walked across the city and visited his friends. The pharynx has nearly regained its function. He converses very well, though some words are pronounced indistinctly; can protrude tongue and purse his lips so as to whistle. The muscles supplied by the lower fibres of the facial have not regained their full power. Paresis of the right side has disappeared. I last saw this patient in July, *en route* to Boston to seek employment. His condition was much the same as in June. He promised to come and see me on his return. This man afterwards came to my office, December 21, 1885, and since the preceding was written, thus verifying his promise.

He tells me he has been running an elevator in a hotel in St. Louis, and has been well since he left here. He has gained in weight, and his general appearance is that of one in health. States that he has not used liquor. When conversing he speaks slowly, and some words are clipped, while the jaw is often drawn to the left. He says he cannot speak rapidly, "because the trouble seems to be in his lips and mouth," and one can see that the lips and tongue fail to perform the more delicate movements necessary to the distinct articulation of many words.

The tongue passes out of the mouth in a straight line. Previous to his sickness he was accustomed to sing a good deal, but now he cannot sing at all. He has no difficulty in swallowing if he exercises care, but if he eats hurriedly he gets choked. Examination shows palatine arch lessened on the right side, and while the levator palatine muscle contracts on the left side that upon the right side remains inactive.

He thinks he can talk better than when he went away in July, and feels much better generally. His mind has remained undisturbed. At times it troubles him to write, for "the letters all run together." Has no trouble with his hands in performing all ordinary duties. Tactile sensibility is about the same in both palms, and is about normal. Upon the back of the hands, right, 2°; left, 4°; dorsum of tongue, normal; right cheek, $1\frac{1}{6}$°; left cheek, $2\frac{2}{3}$°. With the right hand he drives the dynamometer to 65°; with the left to 58°. I can detect no difference in the muscular power of the thighs. The plantar reflexes are slightly exaggerated.

Patellar reflexes exaggerated, the left being more active than the right. When the tap is made upon the right tendon, a distinct contraction takes place in the muscles of the left thigh. No contraction takes place in the muscles of the right thigh when the left tendon is struck. Both radial reflexes normal, others not tested. Bowels constipated, and at times, when he tries to have them act they seem weak. If he laughs heartily, it is often difficult for him to retain his urine, and it will run away upon his clothing. At other times he has trouble to "start his water." States that he has lost all sexual desire, and could not have an erection if provocation presented. There is no evidence that trophic changes have occurred at any point.

In this case a disturbance occurred in the nervous centres, which was manifestly of a serious nature. Bulbar paralysis so pronounced, as well as being the most prominent feature in the case, can leave little or no doubt as to the seat of lesion. The attack having come on while the patient was asleep, it is uncertain to how great an extent the mental functions were disturbed; but I think it is fair to conclude, from the condition of the patient upon the 10th, and from the history of the case subsequently, that the cortical structures of the brain were at no time seriously disturbed. Assuming the lesion to have been in the medulla, its nature and exact seat is far more difficult to decide. The suddenness of the attack would lead one to consider that the lesion was either hemorrhagic or embolic. The age of the patient was against the supposition that it was hemorrhagic. In cases of hemorrhage [1] into the pons or medulla, the vessels, as a rule, are extensively atheromatous. Epileptoid convulsions [2] and apoplectic attacks are of more frequent occurrence in cases of hemorrhage than in those of embolism or thrombosis. The prognosis in cases of hemorrhage is necessarily very grave. There is only hope [3] in cases of limited hemorrhage, or where the

[illegible]

localization is very favorable, especially when it is far removed from the respiratory centre.

It is difficult to conceive of a hemorrhage which, while producing symptoms so pronounced, should cause no more serious disturbance of the functions of the vagus. Pressure of the effused blood upon the respiratory centre, beneath the floor of the fourth ventricle, is the immediate cause of death in these cases. While the functions of the vagus were interfered with, the disturbance was no more than we should look for in certain cases of embolism. Presuming the case to have been one of embolism, which of the vessels was occluded, and at what point did the obstruction occur?

This question cannot be answered satisfactorily in any given case, since it has been found that great variations take place in the distribution of the vessels to this part. Occlusion of the basilar[1] causes paralysis of all four extremities, and of both sides of the face, and usually a rapid death from asphyxia. An obstruction occurring at this point cannot be diagnosed from a hemorrhagic effusion. Obstruction of both vertebrals occasions symptoms similar to those in which the basilar is obstructed. Obstruction of one vertebral artery produces symptoms which assume, to some extent, the hemiplegic form. The lesion is more frequent in the left artery.

The hemiplegia may be on the same side as the lesion, or on the opposite side, depending upon the situation of the lesion, the point of origin of the anterior spinal artery, the completeness of the decussation of the anterior pyramids, and other circumstances. These symptoms may be upon both sides, but they are usually more pronounced upon the one side than upon the other.

Obliteration of the smaller branches of distribution in the medulla cannot be diagnosed during life. In the case above reported, I believe an embolic obstruction occurred in one of the vertebrals, but do not feel sure upon which side the lesion was situated. We read in Ross, second edition, vol. ii., p. 962, under an article upon "Syphilitic Periarteritis and Endarteritis:" "It would appear that distinct gummata may form in the walls of arteries, and either project from its external surface or into its lumen, and in the latter case may either obstruct the vessel completely or be washed off to be arrested as an embolus in one of the smaller branches."

It must be exceedingly rare for complete recovery to take place in these cases, since the arteries going to this part are so largely nutritive and form more or less definite vascular areas.

It is for this reason that secondary structural changes soon follow, which, in many cases, prove fatal. These changes are only averted when a free and prompt collateral circulation becomes established. In the present case it is hoped that a prolonged anti syphilitic treatment may restore the parts to a more healthy condition.

MORRHUOL.—The following is the method proposed by Chapoteant for extracting the active portion of cod-liver oil. The oil is first treated with a soda solution at a low temperature, in order to remove the free acids, and is then shaken up with ninety-per-cent. alcohol. It is then distilled, and the product is the active portion of the oil. Brown oil gives from 4.5 to 6 per cent., yellow from 2.5 to 3 per cent., and white from 1.5 to 2 per cent. of morrhuol. This is a nearly odorless fat, partially crystallized at ordinary temperatures, of a sharp, bitter, and aromatic taste. It is given in capsules of three minims each, corresponding to one and a quarter drachm of cod-liver oil. Children from six to eight years of age receive two, those from eight to twelve years, four, and adults, eight to ten, capsules daily. Lafage states that it may be given for a long time without exciting any digestive disturbances, and he recommends it in tuberculosis, chronic bronchitis, scrofula, and rachitis.—*Allgemeine Medicinische Central-Zeitung.*

Progress of Medical Science.

THE OIL OF EUCALYPTUS IN MALARIAL AFFECTIONS.—In a paper read before the Philadelphia County Medical Society (*Therapeutic Gazette*, June 15, 1886), Dr. J. H. Musser gives the results obtained by the administration of eucalyptus oil in a number of cases of intermittent fever and other malarial affections, and formulates the following conclusions based upon his observations: 1. The oil of eucalyptus is of decided value in about thirty-three and one-third per cent. of all cases of intermitting malarial fever. 2. It has no specific value in any one type of the disease. 3. The longer the duration of the disease, the less liable is it to do good. 4. Relapses are not prevented by it. 5. Its influence on the spleen has not been demonstrated. 6. A dose of ten drops four times daily has been a sufficient dose, but five drops every three hours would be of greater value possibly. 7. Good results are not attained as quickly as by large doses of quinine, but a good effect should be observed within five days at least.

EPILEPSY FROM DISEASED TEETH.—The literature of epilepsy contains some fifteen cases in which this disease was cured by the extraction of one or more teeth, but in none of these cases is it proven that the disease of the teeth was the direct cause of the attacks. The following case, recorded by Schwartzkopf, is apparently conclusive in this regard: The patient, a man aged twenty-seven, suffered severe pain in the right upper middle incisor, which was filled soon after. Thereupon appeared a swelling on the adjacent portion of the hard palate, which increased in size until it reached the soft palate, in which, soon after, a fistulous opening appeared. Every morning the patient expelled, by pressure with his finger, the purulent contents of the swelling, and was thereafter comparatively free from pain. The tooth, however, was loose, and somewhat painful when in use. Ten days after it was filled an epileptic attack occurred, which was repeated after several months. Gradually the attacks became more frequent, and in eighteen months after the first attack they occurred several times a week. The fistula remained during this entire period, and the patient used, under medical advice, bromides, atropine, and other remedies without result. The tooth was then extracted, whereupon the fistula healed, and the epileptic attacks have not returned, although the extraction occurred four years ago.—*The Practitioner*, June, 1886.

A POINT OF DIAGNOSIS IN RÖTHELN.—The extreme infectiousness, notwithstanding the comparative harmlessness, of German measles makes it very desirable to find early indications of its presence. Dr. James G. Glover writes, in *The Lancet*, that he has been struck in two or three cases with the fact that the earliest symptom to excite the notice of the patient has been a swollen gland in the neck at the back of the sterno-mastoid muscle. One young lady consulted him about such a gland of a considerable size, and without any obvious explanation in its neighborhood. Four days later the rash of Rötheln appeared and explained the mystery, and the single gland had become the usual chain on both sides of the neck. When the disease is prevalent, or already exists in a family, and a swollen cervical gland in a young person appears without obvious reason, it may be suspected, the writer maintains, that the disease is already in the system. The occurrence of cervical glandular enlargements is, of course, one of the commonest and most interesting notes of this least pyrexial of the eruptive diseases, and the early appearance of the symptom coincidently with the rash, or even a day before, as Dr. Goodhart describes in one case, is also known. But its appearance four or five days before the eruption seems worth noting for diagnostic purposes.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, August 14, 1886.

WHAT CONSTITUTES COUNTER-PRESCRIBING.

A CASE has recently transpired, bearing on the question of counter-prescribing, which is of considerable interest to medical men, as showing the difficulty of defining in law what actually constitutes medical practice on one hand, and the selling of drugs with a recommendation on the other. A firm of druggists were prosecuted by the Medical Society of the County of New York for prescribing without a license. The facts, as presented in the brief of Mr. W. A. Purrington, counsel for the Society, are in substance as follows:

A laboring man ran a splinter in his foot while at work and went to a druggist on Ninth Avenue for relief. The latter very properly sent him to a doctor for suitable advice and treatment. The patient went as directed, but the doctor being out of his office, patient returned to work and told a fellow-workman (Grimes) of his ill success, and the druggist's refusal to pull out the splinter; then Grimes told him of the defendants and said they were "good for that sort of thing." He went to their shop, saw one of the proprietors, and told him of his visit to the doctor, when the patient was ridiculed for going to the doctor for such a thing, and was informed that the firm were good enough doctors for that, and recited their success in treating an injured woman. The druggist examined the foot with a probe, "advised festering instead of cutting," and applied a salve, charging for the remedy. On Friday the patient called again and then saw another partner of the same firm, whom he told of the first visit, and asked him to extract the splinter. On examination, the latter pronounced it not ripe enough and advised the salve to be put on thicker. On Monday the patient again called. The splinter was then projecting one-eighth of an inch, and the same druggist pulled it out with his tweezers. The patient went home and took to bed. On Tuesday he sent his wife to defendants to get something to relieve his suffering.

The wife testified that she also saw the prescriber and operator, and asked him if he remembered the young man with the splinter, said he was suffering great pain, and asked for something to relieve him. The druggist gave her a wash with directions to apply it every half-hour, saying that her husband probably had erysipelas. On Wednesday she called in a regular physician to attend her husband.

It would appear, then, that the defendants had the case under their care for a week, beginning with the treatment of a wound and ending with the diagnosis of erysipelas.

The defendants met these charges by denying that they applied salve by their own hands or advised treatment.

They say that on every occasion they refused to do anything for the foot, except when one of the firm, observing Hughes' "agony," as he termed it, pulled out the splinter, but mercifully gave no advice. Also that they had no instruments in the shop. The patient only testifies to the use of some sort of a "prod or probe, and probes and tweezers are common instruments in almost every house, and of use also in surgery."

The operator is positive that he gave Mrs. Hughes no instructions as to the use of the wash, because he sold it on Saturday night, *when business was brisk and he had little time to talk!* His attention being carefully called to this, he is as positive about it as about any other thing. And yet it was on Tuesday that he sold it; and his brother testifies that on Friday he had visited the patient after seeing Dr. Hugart, the physician in attendance.

The defendants also testified that the patient *asked for "a salve or something,"* and that the patient's wife picked out from several lotions named the one she wanted.

We have given the facts, pro and con, with some detail, as they bear on many important questions affecting the validity of the present medical law.

Mr. Purrington, the learned counsel of the County Society, presented every possible aspect of the case under the law, argued it with ability and force, but seemingly to no purpose, as the defendants were acquitted, obviously on the grounds of conflicting testimony, but clearly against reasonable probabilities as to intentions against the statute.

The case carries a lesson with it regarding the difficulties in the way of convicting counter-prescribers under the present law. It was ably shown by Mr. Purrington that the defendants voluntarily and culpably assumed the responsibility of medical and surgical advisers, and acted accordingly. Although they received no fee for the same, it did not matter, as professional advice, alas! is often given without pay. But behind it all is shown the usual motives of indirect gain, by being able to sell a medicine which they could not otherwise do. The defendants ingenuously deny any intent of wrong, but rather a desire to be humane in helping the man rather than themselves. With the ordinary jury this counts for a great deal. Hence the verdict. If this case is to be a precedent, the necessity for a more stringent medical law requires no argument.

THE BRITISH MEDICAL ASSOCIATION AND OUR CABLE REPORT.

THE British Medical Association which met this week at Brighton, England, was largely attended, and, as will be seen by our cable despatches, was fully up to its usual standard of scientific work. The addresses were well received, particularly the one on medicine, by our distinguished countryman, Dr. John S. Billings. This address, which we have the pleasure of presenting in full to our readers, will speak for itself. The work in the various sections was of a practical character and will be duly given to our readers when we receive the details by mail.

News of the Week.

The London Hospital Sunday Fund amounts this year to over one hundred and eighty thousand dollars, being $25,000 more than it was last year.

Professor Bouchard has been elected member of the Académie de Médecine.

The Prevention of Post-scarlatinal Nephritis is surely accomplished, according to Professor Jaccoud, by placing the patient on a milk diet from the beginning of the disease, and avoiding cold baths.

Enforcing the Medical Practice Act in Missouri.—The Missouri State Board of Health, following the example of that of Illinois, has passed the following resolution :

Resolved, That in future a percentage of graduates to matriculates of forty-five (45) or over will be grounds for refusal of registration of diploma and issuing of certificates to graduates of a school otherwise in good standing; provided, however, that before such action be taken, the said school, whose diploma is presented for registration, be notified, and an opportunity be given the faculty thereof for satisfactory explanation to the State Board of Health.

Death due to the Inhalation of Nitric Acid Fumes.—Dr. J. W. Stickler, of Orange, N. J., sends us the following interesting account : "Mr. Sinclair, of New Zealand, sent me an account of a very distressing disaster which occurred on board of the Manopouri. It seems that there had been put into the hold of the vessel a case of nitric acid. One of the bottles being broken, the acid escaped, filling the hold with its corroding fumes. Upon one of the hatches being removed the ship was thought to be on fire, and the hold therefore was deluged with water. The men who went below, however, discovered that what was regarded as smoke was in reality a far more irritating substance (nitric acid fumes), although at the time it did not cause a decided burning sensation in the throat or lungs. Within a few hours the men who had been thus exposed began to complain of serious illness, and in a very short time died. Three men sacrificed their lives in this manner. This sad accident is cited to call attention to the fatal consequence of carelessness in the stowage on shipboard of acids, the fumes of which are powerful enough to destroy life when introduced into the lungs by inhalation. In this instance there was gross carelessness on the part of the shippers in not properly marking the case containing the acid. It appears that this practice of shipping dangerous goods without notice of their character (so as to save cost) is a very common one, and the only wonder is that more accidents do not result from it. This sad accident also indicates the rapidity with which the fumes of nitric acid may destroy life when brought into contact with the pulmonary tissue, even when the symptoms immediately following its inhalation do not point to a fatal issue, as was the case in the instance above quoted.

The Michigan State Medical Society has donated $500 to the treasurer of the International Medical Congress.

Richmond County (N. Y.) Medical Society.—At the annual meeting of the Richmond County Medical Society, the following officers were elected for the ensuing year : President, F. U. Johnstone, of New Brighton ; Vice-President, Rudolph Mautner, of Stapleton ; Secretary-Treasurer, J. Walter Wood, of Port Richmond.

The Mississippi Valley Medical Association.—This Association, at its last meeting, did two things—one of which was very creditable ; the other not quite so much so. It elected the editor of the *Weekly Medical Review* its president, and it adopted the American Association's code of ethics. We are informed that it was understood, at the time of its organization, that the Association would attend only to scientific work, and not introduce the subject of medical ethics or medical politics. The results of its change of policy have already been the withdrawal of some members and the development of a quarrel.

Neuro-rheuma is the name Dr. W. Hale White wishes to be applied to nervous energy. It means "that which flows along a nerve."

The International Medical Congress.—*The Lancet* has an editorial annotation pleasantly urging that European physicians make a strong effort to visit the Congress next year.

Obituary.

FRANK HASTINGS HAMILTON, M.D., LL.D.,

For the past two years Dr. Hamilton was suffering from pulmonary phthisis. Although feeble for most of that period, he did not become seriously ill until two weeks ago, when his progressive exhaustion terminated his valuable and useful life on Wednesday, August 11th, at his residence in this city.

Dr. Hamilton was born in the little town of Wilmington, Vt., on September 10, 1813. When still a boy he entered the Medical Department of the University of Pennsylvania, from which he was graduated when he was only twenty years old. After his graduation he went back to his Vermont home for a time, but his ambition sought a wider field, and he made his way to Auburn, N. Y., where he settled down to practice. In a very short time he obtained a widespread reputation as an able young surgeon, and five years after he left college he was appointed Professor of Surgery in the Fairfield (N. Y.) Medical School. This place, for some reason of his own, he did not like, and embracing an opportunity offered a year later, he accepted a similar Professorship at the Geneva (N. Y.) Medical College. Here he remained for nearly four years, when, his ambition again getting the better of him, he gave up his chair and went to Buffalo to resume his practice as a surgeon.

It was in Buffalo that Dr. Hamilton met the late Dr. Austin Flint, and the two thereafter became friends for life. In 1846 they, associated with Dr. James Platt White, also of Buffalo, added to the University of Buffalo a medical department, which rapidly became one of the features of the institution. Dr. Hamilton became its Professor of Surgery. For fourteen years, from 1846 to 1860, he retained his position in the university, and then moved to Brooklyn. Hardly had he got fairly settled in his new home and become the first Professor of Surgery that the Long Island Hospital ever had, when he entered the army as surgeon,

and early in 1861 he was attached to the Thirty-first New York Regiment. He was successively promoted to the grade of Brigade Surgeon—the latter after the battle of Bull Run—Corps Surgeon under General Keyes, in 1862, and Medical Inspector of the United States Army, in 1863. Dr. Hamilton was one of the founders of Bellevue Hospital Medical College, and held its chair of surgery until 1875, when he resigned. He has been living and practising in this city since 1864.

Dr. Hamilton distinguished himself not only as a skilful surgeon, but as a prolific and leading writer on surgical subjects. His famous "Treatise on Fractures and Dislocations," published first in 1860, is justly regarded as the best book on that subject in existence. It has now run through seven editions, and has been translated into French and German. Among his other widely known works are "Prognosis in Fractures," "Treatise on Military Surgery," "Treatise on the Principles and Practice of Surgery," and "New Views on Provisional Callus." The book which Dr. Hamilton regarded with the greatest pride was his "Treatise on the Principles and Practice of Surgery," published in 1872 (the third edition was published a few weeks ago). After he had finished it he remarked one day to his daughter, "Well, now my life is completed."

Dr. Hamilton was also an inventor, and his work in this field has aided surgery very much. Among his inventions are a "bone drill" and an apparatus for broken jaws, and he invented or improved the apparatus for almost every fracture of long bones. One of the doctor's greatest achievements was the introducing of gutta-percha as a splint where irregular joint surfaces require support. He was the first to use gutta-percha as an "interdental splint," and in many practices, which other physicians have since adopted, he was the first to lead. He was a bold and original thinker, firm in his convictions and logical in his conclusions.

When President Garfield was shot, in July, 1881, Dr. Hamilton was honored as one of the consulting surgeons with Dr. Bliss. Until the President died, he, in connection with Drs. Bliss and Agnew, was almost constantly in attendance.

He was twice married—to Mary Virginia McMurran, of Virginia, in 1834, and to Mary Hart, of Oswego, in 1840. His last wife died just a year ago. He leaves two children—Colonel Theodore B. Hamilton and Mrs. Daniel Davis. His body will be privately interred in Sleepy Hollow this (Saturday) morning.

Dr. Hamilton, at the time of his death, held many positions. He was visiting and afterward consulting surgeon to Bellevue Hospital, consulting surgeon to St. Elizabeth's Hospital, to the Hospital for the Ruptured and Crippled, and to various city dispensaries. He was President of the Medical Society of the State of New York, President of the Medico-Legal Society, President of the Pathological Society, and member of many medical societies in New York City.

Reviews and Notices.

THE GENUINE WORKS OF HIPPOCRATES. Translated from the Greek, with a Preliminary Discourse and Annotations, by FRANCIS ADAMS, LL.D., Surgeon. In two volumes. Vol. I. Wood's Library of Standard Medical Authors. New York: William Wood & Co. 1886.

THE learned and scholarly translator of the works of Hippocrates characterizes that author as "the highest exemplar of professional excellence which the world has ever seen." It is most fortunate that the profession of to-day is able, through the scholarship of Dr. Adams, to learn of the life and writings of this man. Dr. Adams' translation was made for the Sydenham Society, and it contains not only the translation of the genuine works but a preliminary account of Grecian medicine, of the physical philosophy of the ancients, and critical notes and explanations of the writings of Hippocrates. A study of the volumes cannot fail, therefore, to instruct and broaden the physician who reads them. The book should be constantly read; it is the Book of Genesis of the medical Bible.

THE PRINCIPLES AND PRACTICE OF SURGERY. By FRANK HASTINGS HAMILTON, A.M., M.D., LL.D., late Professor of the Practice of Surgery, with Operations, and of Clinical Surgery, in Bellevue Hospital Medical College; Consulting Surgeon to Bellevue Hospital; to the Bureau of Surgical and Medical Relief for the Out-door Poor at Bellevue Hospital; to St. Elizabeth's Hospital, and to the Hospital for the Ruptured and Crippled; Fellow of the New York Academy of Medicine, etc. Third edition. Revised and corrected. New York: William Wood & Co. 1886.

THE appearance of the third edition of the late Dr. Hamilton's excellent treatise will be welcomed by many, not only of his former students, but also of others who were denied the privilege of hearing him in their student days, but who knew him by his writings. The interval of time which has elapsed since the second edition of this work was issued has been one fruitful in progress in surgery, and these advances have necessitated many changes and additions in order to bring the book up to the times. These alterations have, with one or two exceptions, been made in a satisfactory manner. As the author took pains to state, the work is in no sense an encyclopædia of surgery, but rather a concise text-book for students, dealing with all the subjects belonging properly and exclusively to surgery, and hence the reader must not expect to find any exhaustive presentation of the history or literature of surgical procedures or theories. We find little mention made of tuberculosis of bones or joints, and one who would turn to this book for instruction in antiseptic methods would be disappointed. The author was no partisan of the parasitic theory of disease, and apparently regarding antiseptic precautions, as practised almost universally in our day, of but little utility, he has dismissed their consideration with few words. But these are matters which, even yet, we venture to say, cannot be regarded as settled beyond the shadow of a doubt, and hence each one is at liberty to hold to his own opinions, even though he be in the minority. For those who desire to learn the views of one of the greatest of the conservative surgeons of the present day we can recommend no better work than the one before us.

HISTORY OF HOMŒOPATHY: ITS ORIGIN; ITS CONFLICTS. With an Appendix on the Present State of University Medicine. By WILHELM AMEKE, M.D., of Berlin. Translated by ALFRED E. DRYSDALE, M.B., of Cannes. Edited by R. E. DUDGEON, M.D. 8vo, pp. 445. London: Published for the British Homœopathic Society, by E. Gould & Son. 1885.

THIS work is an apology for homœopathy, and an attack upon "allopathy," so called. It is not a very good book looked at from a historical, or literary, or scientific stand-point. A great deal of indignant rhetoric is displayed over the persecutions of homœopathists, and we find much of just but oft-repeated criticisms on the fashions of therapeutics. What, as physicians, we should like to find in such a work as this would be a candid statement of what homœopathy has been, and what it really is at present, and also some demonstrations of its efficacy as a mode of treatment. Instead of this we only find tirades and eulogiums, which will please the confirmed adherents of homœopathy, but which can have no effect but weariness on other persons. As the spiritualist sits down to his *Banner of Light*, so the homœopathist can sit down to this work, sure of finding nothing but what will confirm his faith and make him wonder at the obstinacy and dulness of the skeptical world outside.

HANDBOOK OF PRACTICAL MEDICINE. By DR. HERMANN EICHHORST, Professor of Special Pathology and Therapeutics, and Director of the University Medical Clinic at Zurich. Vol. I. Diseases of the Circulatory and Respiratory Apparatus. One hundred and three wood-engravings. Wood's Library of Standard Medical Authors. New York: William Wood & Co. 1886.

EVER since Niemeyer achieved such popularity in this country German works on general medicine have been received with interest and attention. The present work, though coming from Switzerland, is essentially German in its method and thoroughness, and we feel sure that it will be well appreciated here. Its author is widely known for his contributions to pathology, and the translation into English of this, his greatest work, should be a matter of congratulation.

The author's therapeutic suggestions will prove particularly interesting. The book is copiously illustrated, and is printed in the usual excellent style of the Standard Library.

JAHRESBERICHTE UBER DIE FORTSCHRITTE DER ANATOMIE UND PHYSIOLOGIE. Herausgegeben von DR. FR. HOFFMANN und DR. G. SCHWALBE. Dreizehnter Band. Literatur, 1884. II. Abtheilung, Physiologie mit Generalregister zu Band I.–X. Leipzig: F. C. W. Vogel. 1886.

THIS substantial volume of four hundred and eighty pages, besides the general index of ten volumes, presents a concise yet thorough review of the work done in physiology in 1884. Such books as these are exceedingly helpful to all interested in this special branch of the medical sciences.

Reports of Societies.

British Medical Association.

FIFTY-FOURTH ANNUAL MEETING.

Held at Brighton, England, on Tuesday, Wednesday, Thursday, and Friday, August 10, 11, 12, *and* 13, 1886.

(DIRECT CABLE TO THE MEDICAL RECORD.)

TUESDAY, AUGUST 10, 1886—FIRST DAY.

President: W. T. EDWARDS, M.D., F.R.C.S., Physician to the Glamorgan and Monmouth Infirmary, Cardiff.

President-elect: WITHERS MOORE, M.D., F.R.C.P., Senior Physician to Sussex County Hospital, Brighton.

The fifty-fourth annual meeting of the British Medical Association was held at Brighton, and was called to order by the President, DR. W. T. EDWARDS, at 3 P.M., and after a reception of the Council of the Association by the Mayor of Brighton.

The minutes of the last meeting were adopted as read.

DR. EDWARDS, in a brief address thanking the members for the honor conferred on him as the recipient of the high office, and expressing gratification at the good work done by the Society during the past year, introduced the President-elect, DR. WITHERS MOORE, of Brighton.

DR. MOORE took the chair, and followed with an address of welcome to those present, expressing the hope that the meeting would be an enjoyable and profitable one to all concerned.

A vote of thanks was proposed by DR. EDWARD WATER, and seconded by DR. EDWARDS CHADWICK. Carried.

DR. BALTHAZAR FOSTER, President of the Council, moved that the report of Council and financial statement of the Association be adopted. After being seconded by DR. CARTER, of Liverpool, it was carried.

A lengthy discussion then ensued in regard to the admission of new members to the General Medical Council, which resulted in a necessary change in the by laws.

MR. JOHN DIX submitted a proposition in reference to the payment of travelling expenses of the representatives of branches to the meetings of the Council, and recommended that the present by-law on the subject be not altered.

Quite an acrimonious debate ensued, which was only terminated by referring the matter to the Council. The meeting then adjourned until evening.

DR. BALTHAZAR FOSTER, at the beginning of the evening session, introduced DR. N. S. DAVIS, of Chicago, a delegate to the Association, and President of the International Medical Congress.

DR. DAVIS responded in a few appropriate remarks, after which the President, DR. WITHERS MOORE, delivered his

ADDRESS: THE SCIENCE OF PRACTICE[illegible]

After some remarks upon the progress made in the general cultivation of the medical sciences, and the necessity of developing the special departments of practice, he considered, in some detail, the relations of practitioners to consultants. The latter were generally well understood. The object of counsel was mainly the division of responsibility in regard to the management of the case, and both family attendant and consultant should act in unison, with the sole purpose of benefiting the patient. Each party to the consultation had his respective duty to perform, and the line was so sharply drawn by custom that there was no real danger of transcending privileges on one side or the other. When the proper relations were maintained, upon the platform of gentlemanly behavior toward each other, the convictions of the patient and his friends were proportionately strengthened in the estimate of medicine as a science, and in renewed confidence in therapeutical resources.

THE HIGHER EDUCATION OF WOMEN

was his next topic. While on general principles higher education was always desirable, its application to women had comparatively narrow limits. It was not impossible, but its results were not desirable. Women were made for wives and mothers, and in their respective spheres could not be improved by a cultivation of intellectual power at the expense of the finer sympathies of their natures. Physically speaking they were unfitted for the extra strain, and their health, as a rule, suffered accordingly. He believed in Herbert Spencer's maxim, that a strong nation must consist of good animals. Strong and healthy women were of more importance to the rising generation than sickly intellectual female prodigies. Even if health was not broken down, if family duties were not interfered with, if wifely sympathies were not sacrificed, it remained yet to be demonstrated that woman in her so-called higher sphere was a necessary or

useful factor in the body politic. Society needed her help in other directions, and was jealous of her prerogative. In this connection he referred to the overpressure in female seminaries, and the consequent ruination of the constitution at a time when proper rest for the brain and nervous system was a primary consideration. He appropriately concluded his address by quoting from the tenth to the twentieth verse of the last chapter of Proverbs.

Dr. N. S. Davis in proposing a vote of thanks to the speaker remarked upon the influence of the high intellectual cultivation of American women. He believed that woman was abundantly able to occupy her own sphere. She was specially created for it, and should be satisfied with the exercise of these high and noble functions. When she attempted to go beyond them she must necessarily be a failure. She could no more compete with man in his sphere than could man in hers.

The motion was seconded by Mr. Quain, who was proud to own that he was a friend of the President of forty years' standing.

Mr. Marshall introduced a motion to the effect that the *British Medical Journal* should be considered the absolute property of the Association. This gave rise to a discussion bearing upon the methods of management of the journal, which was participated in by Dr. Balthazar Foster, Mr. Wheelhouse, and others, ending in a reference of the matter to the Council.

The meeting then adjourned until Wednesday.

Wednesday, August 11, 1886—Second Day.

The Association was called to order by Sir Balthazar Foster, President *pro tem.*

ADDRESS IN MEDICINE.

After the transaction of some miscellaneous business, Dr. John S. Billings, of Washington, D. C., delivered the address in medicine (see p. 170). The address was well received, and at its conclusion a vote of thanks was tendered by Sir Thomas Crawford. A discussion then followed bearing upon the election of members to the General Medical Council. It was finally decided by vote that the Association should not interfere in the premises.

MEETINGS OF SECTIONS.

The Sections on Medicine, Surgery, and Obstetrics, Therapeutics, and Otology convened this (Wednesday) afternoon.

THE SECTION ON MEDICINE

was presided over by Dr. W. H. Broadbent. Sir Andrew Clark introduced the subject for discussion, viz.:

CASES IN WHICH DISEASE OF THE VALVES OF THE HEART HAS BEEN KNOWN TO EXIST FOR UPWARDS OF FIFTY YEARS WITHOUT CAUSING SERIOUS SYMPTOMS.

He referred to several striking examples of such a condition, in which obstructive and regurgitative troubles were so well balanced by compensatory hypertrophy that the patients were in comparatively good health and many of them able to attend to exacting and arduous duties.

The subject was also discussed by Drs. S. Bristowe, Clifford Allbutt, D. J. Leech, and Bowles.

Dr. W. S. Playfair next read a paper on

SOME OBSERVATIONS ON WHAT IS CALLED NEURASTHENIA.

This was discussed by Drs. Hughlings Jackson and C. R. Drysdale.

THE SECTION ON SURGERY

was addressed, Wednesday afternoon, by its President, John Eric Erichsen, after which Sir Henry Thompson opened a discussion on

SUPRAPUBIC LITHOTOMY,

and was followed by Messrs. Reginald Harrison, of Liverpool, W. Cadge, T. R. Jessop, Barwell, Cousins, Surgeon-Major Kegan, Sir William MacCormac, Jacobson, Bruce, Clarke, and Hingston, of Canada.

THE SECTION ON OBSTETRICS

was called to order by the President, Dr. Alfred Meadows, of London, who delivered an address.

Dr. Robert Barnes, of London, introduced the subject

THE ALTERNATIVES TO CRANIOTOMY,

and was followed in the discussion by Drs. Madden, Neville, Alderson, Cameron, Thompson, Hough, Edis, Wright, Wilson, W. T. Lusk (New York), Galway, and Swaine.

Dr. T. Addis Emmet, of New York, read a paper entitled

CERTAIN MOOTED POINTS IN GYNECOLOGY,

after which Dr. Graily Hewitt gave the early history and etiology of uterine flexions and displacements. The latter was discussed by Drs. Bantock and Gordon.

SECTION ON THERAPEUTICS.

Dr. Thomas Lauder Brunton, of London, the President of the Therapeutical Section, addressed the latter at its opening session, after which Professor Leibrich, of Berlin, read a paper on a new fatty substance (lanolin), detailing its physical properties and therapeutical uses.

Dr. John V. Shoemaker, of Philadelphia, presented a paper on "Hamamelis Virginica," and Dr. E. Mackey one on "Resorcin in Gastric and Cutaneous Disorders."

Dr. Carter, of Liverpool, then opened the discussion on

ANTIPYRETICS,

and was followed by Dr. Leech, and others.

SECTION ON OTOLOGY.

Before the Section on Otology the following papers were read: "On Examination of Nasal Cavities from the Front," by Mr. E. C. Baber; "The Functions of the Nose in Health and Disease," by Dr. Greville MacDonald. Discussions on these papers were participated in by Drs. Erskine, Ellis, Baber, Grant, and Messrs. Spencer Watson and Lennox Browne.

After the adjournment of the sections, a garden party was given to the members by Sir Julian Goldsmid at St. Ann's Wells. This was numerously attended, as was also the conversazione in the evening, tendered by the President of the Association and the Southeastern Branch.

THE AMERICAN OPHTHALMOLOGICAL SOCIETY.

Twenty-second Annual Meeting, held at the Pequot House, New London, Conn., July 21 and 22, 1886.

Continued from p. 137.

WEDNESDAY, JULY 21ST—FIRST DAY—EVENING SESSION.

THE meeting was called to order by the President, Dr. WILLIAM F. NORRIS, of Philadelphia.

DR. J. A. ANDREWS, of New York, read a paper on

THE EFFECT OF THE ELECTRIC LIGHT UPON THE EYE.

The injurious effects of various forms of light upon the eye were first considered, and numerous instances cited showing the harmful effect of exposure of the eyes to bright sun-light, bright lamp-light, etc. Cases were given in which a short exposure to the arc-light was followed by swelling of the lids and conjunctivæ.

The electric light gives the maximum of light with the minimum of heat. So far, the only cases of injury to the eye from the electric light have resulted from exposure in close proximity to the intense light of the arc-light. The effect in these cases can be best explained as occurring through the sympathetic nervous system rather than as the result of mechanical or chemical influences. It is not established that exposure to bright light can produce a diffused iritis. No case of injury to the eye from the incandescent light has been reported. The incandescent light possesses advantages which are wanting in other forms of artificial light, the principal of which are its steadiness and the fact that its use does not contaminate the atmosphere. (The paper will be published in full in a future issue.)

DR. C. R. AGNEW, of New York, remarked that the incandescent electric light had been introduced into Columbia College reading-room, and that all who had made use of it have expressed great satisfaction with it.

DR. W. F. MITTENDORF, of New York, said that the conclusions of Dr. Andrews confirmed the results of his observations. The light is so perfect that it need not be approached close to the eye, and the efforts of accommodation are lessened. On account of its steadiness less work is thrown upon the iris than with the flickering light of the gas.

DR. WILLIAM S. LITTLE, of Philadelphia, described

A METHOD OF OVERCOMING DIPLOPIA WHEN PRISMS ARE NOT FULLY EFFECTIVE.

Double vision, especially in the lower field, is a source of danger in walking. This is the case even where prisms are worn, as the patient, by not holding the head forward, may look under the spectacle and thus see double. In order to prevent looking under the glass and seeing double in the lower field, the speaker had, in a case which he related, resorted to the following procedure. The sphero-cylinder correcting the diplopia of the right eye has been ground opaque for one-sixteenth of an inch above the horizontal plane, so as to obliterate sight in the lower field of vision in this eye. Then there has been attached to the lower portion of the frame the wire network used in protection glasses. This is carefully adjusted to fit close to the face, the perforations in the gauze having been stopped by painting. Vision is thus cut off below and under the spectacle. In this way, vision for the affected eye is only through the upper part of the myopic correction, and the necessity for a prism is done away with.

DR. W. F. MITTENDORF, of New York, read a paper on

TWO EPIDEMICS OF MOLLUSCUM CONTAGIOSUM.

The contagiousness of this affection has been a matter of much dispute. The two epidemics which had come under his notice had occurred in asylums for children. In the spring of 1885, a little girl having one or two small warts on the eyelid was admitted to one of these institutions. In a few weeks other children exhibited similar growths on the eyelids, in some cases spreading to the lips and to the nose. Within three months after the admission of the first case, twenty-seven children were more or less disfigured by this affection.

In the second institution as many as forty children were affected at one time.

As soon as attention was called to the condition, energetic treatment did away with it. Excision with scissors and touching the base with nitrate of silver proved most satisfactory. Unless excision is employed, the disease is apt to return.

DR. W. F. MITTENDORF, of New York, described a case of

MELANO-SARCOMA OF THE CONJUNCTIVA AND ORBITAL TISSUE.

The patient came under observation August 22, 1884. In April of that year a black spot appeared upon the lower part of the conjunctiva and was removed. When she came under observation two other tumors had appeared. They were about the size and shape of cucumber-seeds. Two or three spots, looking as though ink had been dropped on the eyeball, were also noted. The tumors were movable, and the conjunctiva surrounding them slightly congested. Otherwise the eyeball was normal and vision almost perfect. The growths did not affect the left eye, which was highly astigmatic. The patient was a strong, hearty woman, forty-six years of age, with no appearance of cachexia. There had been no injury to the eye, and the family history was good. The pre-aural glands and those of the neck were not enlarged. The tumors were removed and the wound in the conjunctiva brought together with sutures. Healing took place rapidly.

Four months later she returned with two growths starting from the lower portion and the outer canthus of the same eye. There was also a small flat growth on the cornea, not connected with the tumors. The tumors were again removed, and the patient returned to her home.

In the spring of 1886 she again made her appearance, with a small tumor the size of a cherry, which had developed at the seat of the former growths. The tumor, with a portion of the conjunctiva, was removed. A pre-aural gland and some glands in the neck were found slightly enlarged. The general health remained good.

Four or five weeks ago she again returned with another growth. The eyelids could not be separated. An incision was made, and the tumor removed.

Microscopical examination showed the growth to be a melano-sarcoma due to hemorrhage in the parenchyma. Pigment granules were also present.

DR. H. D. NOYES, of New York: In a case of melanotic sarcoma on which I operated some years ago, the disease has not returned.

DR. H. KNAPP, of New York, had operated on a number of these cases, but they have all, after a variable period, relapsed.

DR. B. E. FRYER, of Kansas City, read a paper on

THE USE OF HOT WATER IN SOME OF THE CORNEAL AND CONJUNCTIVAL INFLAMMATIONS.

The water should not be of a lower temperature than 140°, and as much higher as the patient can stand it. It may be used by fomentation applied to the closed eyelids. This is continued for half an hour at a time, and repeated every one, two, or three hours, day and night. It may also be applied by suspending a vessel above the patient, and allowing the water to escape through a tube, thus keeping up a continuous action of the hot water. In some cases the temperature may be raised almost to the boiling point. In some cases of purulent ophthalmia the hot water may be thrown into the conjunctival sac.

In purulent conjunctivitis this application cuts short the attack more quickly and safely than the use of ice-cold

water. In gonorrhœal ophthalmia it quickly lessens the swelling, and diminishes the occurrence of ulceration of the cornea. If ulceration has commenced it is less likely to progress, and the amount of cicatricial tissue is lessened. In catarrhal conjunctivitis and phlyctenular ophthalmia it is a good adjuvant. In acute and chronic keratitis it is useful. Its most marked effects are seen in corneal ulcer. The small amount of opaque tissue left is astonishing. The pain and photophobia are also diminished by the hot water.

Dr. William F. Norris, of Philadelphia, read a paper on

ASTHENOPIA AND THE CHANGES IN REFRACTION IN ADOLESCENT AND ADULT EYES.

The speaker first referred to the changes occurring in the shape of the eyeball at various periods of life. It is regarded by some as not necessary to correct slight errors of refraction, but the author considered their correction as of great importance when they produce asthenopia. By removing the trouble the congestion and softening of the eye is removed, and the lengthening of its visual axis is prevented. This congestion and softening were regarded as important factors in the production of astigmatism and conical cornea.

A number of cases of diminishing hypermetropia and of hypermetropia passing into myopia were described. Diminishing hypermetropia and increasing myopia are simply different stages in a process essentially the same. They are both the result of softening of the eyeball and slow distention in the direction of the visual axis. Careful correction under a mydriator in these cases is one of the best means of preventing their further progress. The enforced rest of the eye thus obtained is an important aid in diminishing the congestion.

Dr. E. Gruening, of New York, referred to an interesting group of cases in which the patient, on arising, has pain in the eyes, with photophobia, passing off in an hour or two. He was not able to fix on any object for any length of time. There is also lachrymation. These symptoms are usually associated evidence of nasal disease. All the affections due to nasal irritation are increased by the recumbent position, for this favors congestion of the erectile tissue of the nose. He has treated these patients by removing the nasal trouble, and in a series of two hundred cases, one hundred and fifty have been benefited, while the remaining fifty have passed from observation.

The meeting then adjourned.

Thursday, July 22d—Second Day—Morning Session.

The meeting was called to order at ten o'clock.

Dr. S. Theobald, of Baltimore, read a paper entitled

THE AMBLYOPIA OF SQUINTING EYES: IS IT A DETERMINING CAUSE OR A CONSEQUENCE OF THE SQUINT?

He criticised the view that the amblyopia exhibited by squinting eyes is a congenital defect, and argued in favor of the older view that the amblyopia is secondary to the squint and due to the mental suppression of the visual image formed in the squinting eye. He stated, in the first place, that it is a mistake to call this variety of amblyopia "amblyopia exanopsia," as the amblyopia is not due simply to want of use of the squinting eye, but to an active cerebral process which induces a much more rapid loss of vision. Schweigger and Alfred Graefe believe that squint is often due to a non-establishment after birth of retinal identity. If this were the case, as there would be, from the first, no stimulus to binocular fixation, the squint ought to develop in early infancy, whereas it is rarely met with then, but usually makes its appearance about the fourth or fifth year. They both also lay stress upon the fact that some squinting eyes (even when there is no alteration) retain good vision for years, while others, which have squinted but a short time, are highly amblyopic. These observations, however, do not conflict with the suppression theory, for, as the amblyopia doubtless develops during the forming stage of the squint, it is reasonable to suppose that, in some cases, it will have reached a high grade by the time the squint is fully established; while, on the other hand, a marked difference in the refraction of the two eyes (because then the diplopia will be less annoying) will explain the retention of vision in the squinting eye.

The most convincing argument, however, in favor of the suppression theory is that the peculiar regional characteristics which the amblyopia exhibits are of just such a nature as we should anticipate if this hypothesis be the correct one, but entirely inexplicable if we suppose the amblyopia to be a congenital defect.

Dr. H. D. Noyes, of New York, did not accept the conclusions presented in this paper. His objections were based upon an experience and careful observation for a number of years. It had been claimed that before the development of the squint such patients have had binocular vision. There is no proof of this, and the evidence is against it. Again, he had the records of a large number of cases of monocular amblyopia, presumably of congenital origin, without lesion demonstrable by the ophthalmoscope, which had had no squint, although there may or may not have heen hypermetropia. Binocular fixation after operation is not infrequent, but, according to his experience, binocular vision is obtained in only one-fifth of the cases. It is rare to find material improvement in an amblyopic eye after operation.

Dr. O. F. Wadsworth, of Boston, agreed with what Dr. Noyes had said. Ten years ago he convinced himself that the amblyopia of squinting eye was not due to disuse. He thought that after operation there is no decided improvement in vision. He had never been able to increase the vision to any extent after operation.

Dr. George C. Harlan, of Philadelphia, said that he had at times attempted to compel the patient to use the affected eye, by keeping the fixing eye under the influence of atropia for a long time, and in some cases he had succeeded in improving the vision in the amblyopic eye.

Dr. W. F. Mittendorf, of New York, said that, while in those cases where there is a central scotoma we cannot expect any improvement from an operation, yet there are cases in which vision is at once improved. He thought that this was to be explained by the removal of the undue pressure exerted by the internal and external recti muscles, which is different from that exerted by the superior and inferior recti. Taking away this pressure puts the eye in a more favorable condition, and we should expect better vision.

Dr. B. Alexander Randall, of Philadephia, reported

TWO CASES OF SEVERE TRAUMATISM OF THE EYE, WITH PARTIAL DISLOCATION OF THE LESSER CRYSTALLINE LENS.

In the first case there were three points of rupture of the sclera. The upper half of the lens was in the anterior chamber, in front of the iris, the lower half, apparently, being in nearly the normal position. The lens receded under rest in bed and other appropriate measures. The scleral rupture healed, and vision increased to about one-thirtieth of the normal. The injured eye shows little tendency to grow worse, although the lens is still luxated backward.

In the second patient, a boy aged twelve, the lens was less markedly luxated, but the ophthalmoscope showed two rents in the choroid, the larger a little outside of the macular region, the other close to the temporal margin of the optic disk. The case progressed to an excellent recovery. The appearances of the eye-ground were illustrated by colored sketches.

Dr. J. S. Prout, of Brooklyn, read a paper on

RADAL'S OPERATION—EXCISION OF THE INFRA-ORBITAL NERVE FOR THE RELIEF OF GLAUCOMA, WITH CASES.

In 1882-83, Badal, of Bordeaux, proposed the excision of the infra-trochlear nerve for the relief of glaucoma accompanied by pain. He selected this nerve because it is the direct extension of that branch of the ophthalmic, the nasal, from which the eyeball received its nervous supply. It emerges from the orbit just below the insertion of the pulley of the superior oblique muscle. It is readily reached by an incision along the margin of the orbit running from the pulley to the upper margin of the tendon of the orbicularis muscle. It is small, soft, and not easily recognized. It is to be stretched and torn by pulling directly forward. The *rationale* of the operation is not explained.

In severe cases, when a short delay may be fatal to the eye, Badal advises that the operation be combined with evacuation of the aqueous humor.

Dr. Prout had performed the operation nine times on five patients, which he reported. All were unpromising cases. In one there was for a time decided improvement of vision; in one there was temporary relief from moderate, and one from severe, pain. One was a case of glaucoma simplex, operated on without benefit; another a case of hemorrhagic glaucoma, not benefited. Others have reported much better results.

Dr. Prout drew the following conclusions: The operation has been shown to deserve further trial, especially in cases unfit for operations on the eyeball. It cannot make matters worse as to the eyes. Relief of pain, even if only temporary, is worth procuring at the cost of so slight an operation. It is important that cases be recorded, so that its value may be ascertained.

Dr. C. S. Bull, of New York, stated that where he had performed the operation for the relief of pain in glaucoma or ciliary neuralgia, while the relief was marked immediately after the operation, it was temporary only, and in every case returned.

Dr. H. Knapp, of New York, read a paper on

ADVANCEMENT OF TENON'S CAPSULE IN STRABISMUS.

The operation is performed by De Wecker in the following manner: A piece of conjunctiva, five millimetres long and ten millimetres high, is detached from the region of the insertion of the tendon, leaving a small band near the cornea. Tenon's capsule is now incised near the insertion of the tendon, and loosened alongside of and under the muscle. The capsule is then stitched forward by two sutures, entering through the conjunctiva to the capsule at the lower and upper edges of the muscle, and coming out in the conjunctiva above and below the cornea.

Dr. Knapp, during the last few months, had done the operation ten times. His operation differed from that above described in leaving a broader conjunctival flap and in using a third middle suture. The operation was performed in two cases of convergent strabismus due to paralysis of the external rectus, two cases in which former tenotomies had not overcome the difficulty, and in six cases of convergent strabismus of high degree, with considerable amblyopia. The results have all been quite good.

In none of the cases has there been any alarming reaction. Antiseptic precautions have been employed in all cases. The speaker preferred advancement of Tenon's capsule to simple advancement of the tendon, because the operation is simple and attended with less risk. His experience with limited advancement of Tenon's capsule has been quite encouraging.

Dr. J. S. Prout, of Brooklyn, read a paper on

NEW-FORMATION IN THE VITREOUS OF BOTH EYES.

In the right eye there is a body arching forward. There is no evidence of any relation to the papilla. The speaker thought that it was in all probability a remnant of the fœtal circulation of the vitreous. In the left eye there was a similar body. Drawings showing the appearance presented were exhibited.

Dr. Emil Grüening, of New York, reported

A CASE OF [illegible]

Dr. Edward Jackson, of Philadelphia, presented a lens series for the refraction ophthalmoscope.

Dr. John Green, of St. Louis, exhibited and described a new series of test-letters.

Dr. Charles A. Oliver, of Philadelphia, presented a set of metric test-letters and words for determining the amount and range of accommodation.

Dr. S. D. Risley, of Philadelphia, described

A CASE OF [illegible] ALBUMEN [illegible] INDUCED PREMATURE LABOR.

The patient, the wife of a physician, was seen when she was between the fourth and fifth months of pregnancy. She had suffered with headache and giddiness. The urine had been examined a week previously and no albumen found. At this time there was marked disturbance of vision. In a previous pregnancy she had had albuminuria, but no trouble with sight. In a second pregnancy there had been no trouble. The ophthalmoscope showed albuminuric retinitis of both eyes. The urine contained a large quantity of albumen. After consultation, the induction of abortion was advised.

Labor was induced, and she was delivered of a fœtus at five months. She then passed into an unconscious condition, in which she remained four days. There were no convulsions. As consciousness gradually returned, evidences of right-sided hemiplegia with aphasia were noted. The quantity of albumen gradually diminished, and six months later the lady was able to return to her ordinary duties. There were still some traces of aphasia, but vision was greatly improved.

Dr. B. Alexander Randall exhibited a modification of the Loring ophthalmoscope, which consisted in adding a series of cylinders.

Dr. J. A. Andrews, of New York, read a paper on

THE FREQUENT INSTILLATION OF A TWO-PER-CENT. SOLUTION OF NITRATE OF SILVER IN PURULENT OPHTHALMIA.

He had employed this method in twenty-five cases of gonorrhœal ophthalmia, and the eyes were seriously damaged in none of them. The cases were all severe, with much discharge, chemosis, and swelling of the lids. The applications were repeated usually three times a day; sometimes as often as five times per day. The use of the nitrate of silver is graduated to the amount of hyperæmia, and especially to the amount of swelling of the lids. If this be marked, instillations may be repeated frequently.

Dr. Russell Murdoch, of Baltimore, exhibited an impervious covering for the sponge in the administration of ether.

Dr. H. D. Noyes, of New York, read a paper on

MEASUREMENT OF ASTIGMATISM BY THE OPHTHALMOMETER OF JAVAL AND SCHIOTZ.

The following papers were read by title: "Burns o the Eye by Fulminate of Silver and Fulminate of Mercury," "Cases of Foreign Bodies in the Globe, including Two Cases of Spontaneous Extrusion."

OFFICERS ELECTED.

President—Dr. William F. Norris, of Philadelphia.

Vice-President—Dr. Haskel Derby, of Boston.

Secretary and Treasurer—Dr. C. [illegible] of Boston.

Corresponding Secretary—Dr. J. S. Prout, of Brooklyn.

The next meeting will be held at the Pequot House, New London, Conn., on the third Wednesday of July, 1887.

Adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 23, 1886.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

DR. V. P. GIBNEY presented, in behalf of a candidate, specimens illustrating certain lesions of *club-foot.*

REPORT OF THE COMMITTEE ON MICROSCOPY.

DR. G. C. FREEBORN, from the *Committee on Microscopy*, reported that the *enlarged bronchial glands* presented by Dr. J. Lewis Smith contained tubercle bacilli well marked.

The brain specimen presented by Dr. Putnam-Jacobi at the last stated meeting revealed no evidence of carcinomatous growth.

The tumor presented by Dr. Wylie at the last stated meeting was a *calcified dermoid cyst.*

DR. H. MARION SIMS presented a rather rare specimen of

DOUBLE FIBROID OF THE OVARY,

which, when removed, weighed between five and six pounds. The patient was sixty-three years of age, was operated upon three weeks previously, and made a good recovery without any unfavorable symptoms. Change of life occurred eighteen years ago. She was the mother of one child, twenty-six years of age. In March last she first noticed a swelling in her abdomen, but supposed that it was due to wind in the bowels. It did not yield, however, to such domestic remedies as were used, and she consulted a physician in Summerville, N. J., who recognized a tumor, and referred her to Dr. Sims, who diagnosticated probable fibroid of the ovary, with ascites, and removed it by operation as already stated. The abdominal incision was about seven inches in length. The tumor was firmly adherent posteriorly in the cul-de-sac, and an unusual amount of force was required to break up the adhesions. The pedicle was long and rather broad; it was ligated with silk and dropped. A drainage-tube was introduced, which was removed on the second day, and from that the patient went on to recovery rapidly.

DR. RICHARD T. BANG presented a specimen of

SPINDLE-CELLED SARCOMA OF THE BREAST.

Mrs. T——, thirty years of age, and a native of the United States; has been married nearly five years, but has had neither children nor miscarriage. Family history perfectly good. The patient has always enjoyed excellent health, which has been but slightly impaired by the occurrence of this growth. About four years ago, without any known cause existing therefor, she noticed a small lump about the size of a hazel-nut in the upper and outer portion of the left mamma. This lump gave her absolutely no inconvenience, and it increased in size so slowly that at the end of three and a half years it was but slightly larger than an English walnut. At this time (in December, 1885) she received a severe blow on the breast by accidentally falling over a chair, and from this moment on, the tumor grew most rapidly, so that when I saw the patient for the first time, on May 6th last, I found fully two-thirds of the mammary gland involved by the growth. There was no retraction of the nipple, and only occasional slight pain was complained of. A solitary, very moderately enlarged gland (about the size of a cherry-pit), was found in the left axilla, and no cachexia or depreciation of the general health existed. The skin over the tumor was unbroken, and not implicated by the growth, and the tumor itself was freely movable and unattached to the pectoral muscles. The mass involved the upper and outer two-thirds of the breast, and was stony hard, solid, and heavy to the feel. Just above the nipple pretty deep-seated fluctuation was discovered, and a probable diagnosis of either cystic sarcoma or fibroma having been made, the patient was advised to have the entire gland extirpated. Dr. McBurney, who saw the case in consultation, concurred both in the diagnosis and in the advice given. On June 2d he accordingly, with the assistance of Dr. A. Blauvelt, performed the operation in the usual manner. Corrosive sublimate solution, 1 to 1,000, bone drainage-tubes, and catgut ligatures and sutures were employed, and the wound was dressed with iodoform, iodoform gauze, bichloride gauze, wood-wool, etc. This first dressing was allowed to remain on for ten days, and when it was removed the wound was found to be perfectly healed, excepting a small sinus at either end. Two more dressings have been applied, and this morning both sinuses were found perfectly and firmly healed, and the patient was discharged cured.

The temperature remained normal throughout the treatment.

On section the tumor was found to be made up of a dense, white, lobulated structure, in which was found a cyst which contained about three tablespoonfuls of a sanguineous fluid. The tumor had been examined by Dr. Frank Ferguson, who reported it to be a typical spindle-celled sarcoma.

The Society then went into executive session.

Correspondence.

OUR LONDON LETTER.

[From our Special Correspondent.]

THE TEMPERANCE CONGRESS—DR. RICHARDSON IN A NEW ROLE—DR. NORMAN KERR ON LEGISLATION FOR HABITUAL DRUNKARDS—MR. KNAGGS ON TRINIDAD—THE LONDON TEMPERANCE HOSPITAL—SMALL POX AND THE ARRANGEMENTS FOR ISOLATION—A CONVALESCENT HOSPITAL FOR LONDON—SOCIETY OF MEDICAL MEN QUALIFIED IN SANITARY SCIENCE—THE SOCIETY OF APOTHECARIES—THE EXODUS FROM LONDON.

LONDON, July 1, 1886.

THE event of the past week has been the British and Colonial Temperance Congress. The profession has not been unrepresented. Dr. Richardson turned up as usual, and on this occasion appeared in a new character, viz., that of an anti-tobacconist. It is to be hoped he will not stump the country on a crusade against nicotine—not but what plenty may be said against it—but the learned doctor is so enthusiastic when he does take up any cause that there is no knowing what he may do. Should he take up the subject, I trust he will not fail to denounce the increasing custom of smoking among mere boys. The number of youthful smokers to be seen in the streets of London is something appalling.

To return to the Congress. Dr. Norman Kerr, who seems to have an insatiable appetite for statistics and tables, read a paper on "Colonial Legislation for the Habitual Drunkard." He referred first to the laws on the subject in force in the United States, and said that the generous and thoughtful provision there made for the victims of the mightiest tyrant on earth put to shame our own disgraceful neglect of an urgent duty. Referring then to our own colonies, he said that they, too, put us to the blush. He then gave a brief *résumé* of the legislative enactments in force in Ontario, Quebec, Nova Scotia, New Brunswick, Manitoba, South Australia, and New Zealand, and pointed out that in these colonies compulsory and permanent laws were in force, whereas our own Habitual Drunkards Act was but permissive and only a temporary measure, its operation being limited to ten years.

Mr. Robert Knaggs (Port of Spain) read a paper on Trinidad, and referred to the number of lives which had been sacrificed there under the notion that alcohol was a necessary stimulant in a depressing tropical climate. In the last twenty-five years twenty-seven members of the medical board had died, and twelve of these owed their premature disease to free living in the matter of

alcoholic drink. Temperance had made some recent progress in the island, and Mr. Knaggs said he believed the drinking customs were being slowly undermined. The doctors were now far more cautious in giving alcohol to their patients, and particularly so in regard to taking it themselves.

After the Congress, the delegates present were invited to visit the London Temperance Hospital. First opened in 1873, it has been successively enlarged until at present one hundred and twenty patients can (as soon as funds permit) be accommodated in the new building in the Hampstead Road. Since the foundation of the hospital, 3,486 in-patients have been admitted, of whom only 183 have died. No alcohol is given unless specially prescribed, and it has been ordered in only a very few cases. In fifty-three cases of typhoid fever it was not given once. Out of the 53 typhoid cases in the ten years ending April 30, 1884, only 5 died, and but one of these was an abstainer. The medical staff are now preparing for publication a series of special tables, showing the results of the treatment of a number of acute diseases without alcohol.

The small-pox epidemic in London has virtually disappeared. One of the elements contributing to this desirable result has doubtless been the admirable arrangements for isolation made by the Metropolitan Asylums Board. Five land hospitals and one floating hospital are under the control of the board for the reception of small-pox cases. In connection with these are three ambulance stations, three steamers for conveying patients to the floating hospital at Purfleet, and two wharves from which they can be consigned from the ambulances to the steamers—a third wharf being now in course of construction. Where possible, patients are taken by steamer down to the floating hospital at Purfleet. During the severe epidemic of last year the river steamers carried 10,971 patients between London and Purfleet, about half of this number being convalescents returning from the floating hospital and convalescent camp. These, of course, are isolated from the patients. During the last epidemic the floating hospital (which consists of two ships for patients, and a third to accommodate the hospital staff) had at times as many as four hundred patients on board, more than a hundred sometimes going down the river in steamers in the course of the day. At present only ten patients are at Purfleet.

An executive committee, of which Sir J. Risdon Bennett, M.D., is chairman, has been formed to carry out a scheme for founding a convalescent hospital for London. This scheme was set on foot last year, and is now in a fair way of being realized. A special feature of the new institution is that medical and surgical treatment is to be provided for its inmates, and it will therefore differ very largely from the numerous convalescent homes, excellent institutions as many of the latter are in their way.

A society of medical men qualified in sanitary science has been formed, with Sir Joseph Fayrer as its president. The first annual meeting has just been held.

The Society of Apothecaries, which was shut out by the two colleges when they combined together for examination purposes, has now applied to join the combination, and the authorities at Blackfriars have pointed out that if not allowed to do so, they will be able, under the new medical act, to appoint assistant examiners and confer a statutory diploma. This would expose the two royal colleges to a very serious competition.

I must now pause and allow your Brighton representative to take up the tale; he will, no doubt, send you an account, not only of the Brighton meeting, but of Brighton itself, from a medical point of view. Everyone who can is now leaving town, and as next week the centre of medical life will be shifted to Brighton, I propose to resume the correspondence from London after the great gathering at Brighton has dispersed and my Brighton colleague bids me resume my pen again.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from [illegible], 1886.

MURRAY, ROBERT, Brigadier-General and Surgeon-General, U. S. A., retired, August 6, 1886.

BENTLEY, EDWIN, Major and Surgeon. Ordered from Department of Texas to Department of the East. S. O. 179, A. G. O., August 4, 1886.

APPEL, D. M., Captain and Assistant Surgeon. Ordered from Department of the East to Department of Texas. S. O. 179, A. G. O., August 4, 1886.

MIDDLETON, PASSMORE, Major and Surgeon. Granted leave of absence until September 10, 1886. S. O. 100, Division of the Atlantic, August 3, 1886.

WHITE, R. H., Captain and Assistant Surgeon. Ordered from Angel Island, Cal., to San Diego Barracks, Cal., relieving Captain Leonard Y. Lorings, Assistant Surgeon. S. O. 64, Department of California, July 28, 1886.

APPOINTMENT.

To be Assistant Surgeons with the rank of First Lieutenant, A. G. O., August 2, 1886:

HARRIS, HENRY S. T., January 5, 1886.
WOOD, LEONARD, January 5, 1886.
BANISTER, WILLIAM B., January 26, 1886.
MASON, CHARLES F., May 5, 1886.

PROMOTIONS.

To be Surgeons with the rank of Major, A. G. O., August 2, 1886:

BARTHOLF, JOHN H., Captain and Assistant Surgeon, January 4, 1886.

KIMBALL, JAMES P., Captain and Assistant Surgeon, January 24, 1886.

Official List of Changes in the Medical Corps of the United States Navy, from [illegible], 1886.

RUSH, CHARLES D., Passed Assistant Surgeon. Detached from the Receiving Ship Franklin and ordered to the U. S. S. Pinta.

WILLSON, W. G. G., Passed Assistant Surgeon. Detached from the U. S. S. Pinta, ordered home and await orders.

THERAPEUTIC NIHILISM AT VIENNA.—In 1877, during my trip from Paris here, I made the acquaintance of a very intelligent English attorney. He said, "You are going to Vienna to study?" I answered in the affirmative. "Well," he said, "I want your card, for I am going next year to America, and may need a physician, and I want a man who has studied at Vienna." I asked why. He replied, "This is the reason. The old school give large doses of medicine, homœopathists give small doses, but the Vienna school give none, and that is what suits me." He was not far from the truth. All the remedies that Professor Bamberger has prescribed this term could be counted on the fingers of both hands. No aconite; in fact, no arterial sedative; digitalis as a heart-tonic and diuretic; quinine only occasionally, where a very high temperature exists that does not yield at once to cold baths or sponging. His frequent use of calomel reminds one of his father's practice forty years ago. Cold baths are less frequently and persistently used than ten years ago. One hour and a half Bamberger often gives to the delineation of a single case, but of this time five minutes suffices for all he has to say as to its therapeutical management.—Vienna Cor. *Weekly Medical Review.*

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending August 7, 1886:

	Cases.	Deaths.
Typhus fever	2	1
Typhoid fever	29	3
Scarlet fever	11	1
Cerebro-spinal meningitis	3	3
Measles	15	—
Diphtheria	55	27
Small-pox	—	—

Why some Young Doctors go to Europe.—I asked a new graduate of one of our Western schools, where I know clinical advantages are at a minimum, to go with me to hear Bamberger. His first question to me was, "Doctor, what is your specialty?" My reply was internal medicine in its broadest sense, with all the gynecology I can find to mix in. His reply was, "Doctor, you make a great mistake; take some specialty, that is all the rage in America! I am after the throat, and when I get back to Indiana I shall expect to do a big business." What absurdity, when we consider the vast and intimate relation of the diseases of the throat and nose to other organs of the body, for a young man to take up such a specialty before he is a thorough physician in the widest acceptation of that term. He further told me he did not understand German, and had no idea of attempting to learn it; that he had spent some time in New York in a throat clinic, and he believed that the advantages there were far superior to what could be gotten in Vienna, but that a man must have the reputation of having studied in Vienna, or it was no go in a large town in America.—Vienna Cor. *Weekly Medical Review.*

The Association of American Physicians.—A Washington correspondent of the *Journal of the American Medical Association* charges that this new organization has been established in opposition to the American Medical Association, and with the design of absorbing or destroying it. He seems to be a little worried over the contrast which he says will be attempted to be made between the Association of American Physicians and the American Medical Association in the eyes of the medical world, and inquires, somewhat irrelevantly, whether the American Medical Association is "to be degraded by a set of men in its own ranks, in a profession which teaches and has always taught [and practised?] fraternity of feeling and good-will toward its fellows." A terrible prophecy is the peroration: "The day will come when such as seek to destroy the great temple of medicine in such ways—by caprice and whims and spitefulness—will wofully repent it, will abhor themselves sooner or later, and be ashamed of their associates who, with themselves, lifted a hand or voice to aid in such nefarious work."

Accuracy in Compounding Prescriptions.—The result of a curious but very important test as to the accuracy with which chemists, druggists, and others make up prescriptions committed to their care has recently been presented to one of the London vestries. Fifty prescriptions were sent out to ordinary druggists, to co-operative stores, to "doctors' shops," and to certain traders styling themselves drug companies. The mixtures made were afterward analyzed to find out how nearly they agreed with the prescriptions they represented; but in order to give a liberal margin for error, it was resolved not to put a black mark against anyone if the chief constituents were within ten per cent. of the amount ordered; in one instance it was fifty-seven per cent. in excess. The chemists and druggists came out best in this strange competition, as only six per cent. of their prescriptions had to be called in question. Next came the co-operative stores, with twenty per cent. of error; then the "doctors' shops," with fifty per cent.; and lastly the drug companies, who are credited, or rather discredited, with seventy per cent. of errors.—*Provincial Medical Journal.*

Effect of Mental Overwork upon the Teeth.—Among the hard-worked pupils of the Paris public schools the teeth become deteriorated in a few weeks after entry. The second dentition is often premature. These observations confirm the statements of Dr. J. L. Williams, who has given great attention to this subject. He has shown that any mental strain shows itself upon the teeth in a short time, both in increased decay as well as in increased sensibility of the dentine. Dr. D. M. Parker has reported that these same changes are always apparent in men who are in training for athletic trials.—*Boston Medical and Surgical Journal*, June 3, 1886.

Spontaneous Transformation of Morphine into Apomorphine.—A solution of hydrochlorate of morphine for subcutaneous injection (three per cent.) was ordered for a patient, and its injection was promptly followed by relief of the pain without any gastric symptoms whatever. Eleven months later the patient made use of the same solution; but this time the injections gave rise immediately to violent and uncontrollable vomiting. The solution was given to a well-known analyst at Paris for examination, and he ascertained that apomorphine was present, thus accounting for the sickness. He recommended in consequence that solutions of the salts of morphine should never be kept longer than four weeks, and that freshly prepared solutions should not be mixed with the old.—*British Medical Journal*, June 26, 1886.

Babies and Perambulators.—Several writers in the English medical press have recently called attention to the dangers to which infants are exposed when wheeled about in the ordinary way in their perambulators. It is stated that many diseases of the throat and chest are caused in this way, and the remedy proposed is that the children shall sit or lie facing their nurses. The back of the perambulator will thus protect the child from the wind, and at the same time it will be more directly under the eye of the nurse, whose view will not be obstructed by the wagon-top.

The Use of Ergot for illicit purposes has increased so much in Rome that the prefect has issued a circular to the syndics of the city and province, calling upon them to enforce the regulations as to the sale of the drug. It seems that the same medical prescription is unlawfully used for its purchase over and over again, in spite of a pontifical regulation still in force. Pharmacists and midwives are cautioned that if they violate the regulation they will be denounced to the judiciary authorities for criminal proceedings, and if convicted, the severest penalty will be imposed.—*Medical Press and Circular.*

Vaccination in Japan.—The Japanese do not appear to have lost any of their faith in the efficacy of vaccination for the small-pox. They have just enacted a very stringent law on the subject, for, besides ordinary vaccination in the first year of infancy, it provides for at least two subsequent revaccinations at intervals of from five to seven years, so that by the time a child has reached its fifteenth year it will have been vaccinated three times. During epidemics of small-pox, local authorities also have power, when they deem it necessary, to order the vaccination of all the inhabitants of their districts, irrespective of the vaccinations required by the law.—*Sanitary Record.*

Medical Education.—There are in the United States no fewer than 89 regular medical colleges, with about 10,000 medical students; 8 of these medical colleges have each from 300 to 600 students, and 7 of them have from 200 to 300 students.

A New Method of Taking the Temperature.—Filatoff recommends that the temperature in children should be taken by previously warming the thermometer and then observing the degree of heat, instead of the use, of the mercury. The thermometer bulb is placed in the axilla, and it is asserted that not more than two minutes are required for obtaining a very accurate record of the temperature.

A New Berlin Society.—An association has been formed in Berlin, of dentists who have received their scientific education and training in America. It is called the "German Association of Doctors in Dentistry Graduated in America," and has established a *Journal für Zahnheilkunde* which is to be the organ of the Society.

Confusion in the Treatment of Scarlet Fever.—Dr. J. M. Sooy, of Philadelphia, writes to show how the therapeutists of the regular and of the homœopathic schools have erred in their modes of administering belladonna in scarlet fever. Belladonna, he says, given in small doses produces dryness, paleness of the skin, and sometimes a bluish color of the mucous membranes. This anæmia is caused by the contraction of the arterioles, the agent being a stimulant to the vaso-motor system; but when belladona is given in larger doses it causes dilatation of the arteries and a fall of blood-pressure. This action is induced by an overstimulation of the vaso-motor nerves, and it is the secondary, and not the primary, action of the drug which gives to the superficial parts an appearance not unlike scarlatina. If now a small dose cause anæmia, it is evident that such a plan of treatment would reduce the inflammatory material. But this is not according to the laws of homœopathy, but of antagonism. If large doses should be given, there would be overstimulation of the vaso-motor system, and a condition not unlike the eruption of scarlatina would result. This would be according to the law of similars, but would not be productive of beneficial results. In regular practice belladonna has been abandoned in the treatment of scarlet fever, and has been proclaimed as worse than useless, because his deficient knowledge of therapeutics has led the physician into homœopathy; whereas the homœopathist still speaks in high terms of the many virtues of the drug, owing to the fact that he has followed ignorantly the law of antagonisms, and not the law of similars, and has, consequently, obtained good results.

A very Democratic Correspondent writes us: "I have long been a reader of The Record, and have noticed in its contributions and proceedings of the various societies the language almost invariably used by members of the profession. We were all taught in our younger days that in the United States there was no such a thing as classes among her citizens. Observe the allusions so often quoted: 'The upper, the middle, and lower class of patients.' It sounds too monarchical; the words should have no place in an American journal; but probably its English or imported, you know; or can it be possible the country has a class of Cæsars acting as physicians and surgeons?"

Hydronaphthol and Beta-naphthol.—Beta-naphthol was introduced by Kaposi in 1881 as a parasiticide in diseases of the skin, but was soon found to be a dangerous poison, even when applied externally, and its field of usefulness was consequently much restricted. Recently a new antiseptic agent, called hydronaphthol, has been brought to the notice of the profession by a firm in this city. It seems to be nearly related to beta-naphthol, although it differs from it by its melting-point, shape of crystallization, and reactions. It has been stated by Professor Jacobsen, of Berlin, that the two were identical, but Dr. Justus Wolff sends us a communication asserting that this is by no means the case. Samples of beta-naphthol, declared by Professor Jacobsen to be chemically pure, and of hydronaphthol, were obtained, and equal parts of each were given to two rabbits. The rabbit which had received the beta-naphthol died in a short time, but the one to which an equal quantity of hydronaphthol had been given did not seem to feel any effects at all and remained healthy and vigorous. Dr. G. R. Fowler reported in the *New York Medical Journal* a number of successful operations in which hydronaphthol had been employed as the only antiseptic, and in which no untoward effects had been observed, and none at all resembling those reported by others as resulting from the action of beta naphthol. Dr. Wolff concludes therefore that two chemical compounds, of which one is a deadly poison and the other not poisonous at all, are not identical in their composition or chemical constitution, and must be two distinct substances.

A Well-Proven Test.—Before commencing the autopsy, Dr. Crevenger recommends holding the hands over strong liquid ammonia, when the smarting which ensues will reveal all sensitive or abraded places that need a touch of caustic before beginning the examination.—*Weekly Medical Review*.

New Method of Preparing Fehling's Solution.—Schmiedeberg uses mannite in place of Rochelle salt in making Fehling's solution. He claims that the addition of mannite insures stability to the solution. His formula is as follows: Dissolve 34.632 gm. of crystallized copper sulphate in 200 c.c. of water; to this solution is added a solution of 15 gm. of very pure mannite in 100 c.c. of water and 480 c.c. of solution of caustic soda (1.145), and, lastly, sufficient water to make 1 litre.—*American Journal of Pharmacy*.

The Dead in the Morgue.—We do not think it right that a Chicago medical college should procure its anatomical material from the St. Louis "Potter's field."—*St. Louis Weekly Medical Review*.

The Watermelon.—Prof. [illegible] recommends the watermelon as a cheap but effective substitute for grapes in the treatment of chronic congestion of the liver, chronic intestinal catarrh, and similar affections.

New Metric Abbreviations.—The International Committee of Metric Weights and Measures has adopted the following system of abbreviations. Italics are employed, with the exponents 2 and 3 to denote square and cubic measure: Metre=*m*, decimetre=*dm*, centimetre=*cm*, millimetre=*mm*, kilometre=*km*. Metre square=m^2, metre cube=m^3, and so for the rest. Litre=*l*, decilitre=*dl*, etc. Kilogram=*kg*, dekagram=*dkg*, gram=*g*, decigram=*dg*, centigram=*cg*, milligram=*mg*.

The Manufacture of Skeletons.—A correspondent of the *Medical Press and Circular* describes what he saw in an establishment for the preparation of skeletons in Paris. He made the acquaintance of a female "bone-peeler" at one of the hospitals, and was conducted by her to the factory, situated in the outskirts of Paris. The building to which he was conducted was an immense wooden construction subdivided into a main *atelier* and out-houses. The larger room was occupied by a series of large cauldrons, the emanations from which were, even to one accustomed to the suave odor of the dissecting-room, nauseating in the extreme, and the blend formed with that of various crude antiseptics was more peculiar than fascinating. On stirring up the *soupe* contained in the cauldrons with a broomstick, a heterogeneous collection of limbs was seen, many of them having evidently been amputated. A grinning head, with glaucomatous eyes and fleshless lips, came to the surface now and again with a ghastly leer, which was at once lost in the froth which covered the seething liquid. The disarticulation of skulls is carried on separately, as it is a branch requiring greater skill and nicety in its manipulation. It is effected on the skulls of young adults or children by filling the emptied cranial cavity with dried peas, which are

then steeped in water, and in swelling compel the disjunction more delicately than could be done in any other way. After prolonged boiling the limbs are placed on a table and the adhering tissues carefully removed, each workman or workwoman having his or her own specialty. The bones are then bleached, the cheaper varieties simply by means of chloride of lime, the better ones in the sun, and they ultimately pass into the finishing-room, where they are assorted, and converted, as far as may be, into "articulated skeletons." It requires no small amount of ingenuity and knowledge of this particular department to be able to choose out of the miscellaneous collection of bones wherewithal to construct a skeleton which shall pass muster for that of a single individual, and only the best bones are so adapted, the remainder going to make up the disarticulated and half-skeletons which have to answer the purposes of study for the more economically disposed students. In another tank, awaiting treatment, were a number of infant bodies, varying from minus four months to plus several days. In the show-rooms they were arranged in a graduated scale (*échelle mortante*), from the diminutive little ex-mortal, whose height did not exceed four inches, to the adult baby measuring from eighteen to twenty, all being in the attitude known in the military world as that of "attention." These have a special value of their own, far greater in proportion to their size than that of their bigger brethren. The supply was obtained from the hospitals and dissecting-rooms and in part also from the various convict establishments.

A Novel Obstetrical Experiment.—Dr. Shustoff writes in *Russkaya Meditsina*, of April, 1886, that he was called to see a woman who had been in labor five days. The pains had begun well but had since ceased. Upon examination he saw something black protruding from the anus, and a little pulling brought to light a sausage over seventeen inches long and fourteen inches in circumference. The pains now began again, and the woman was soon delivered of a dead child. Dr. Shustoff found on inquiry that the sausage had been introduced on the recommendation of an old woman of the neighborhood, in order to insure the birth of the child by the normal passage. This was probably the old wife's best attempt at supporting the perineum.

Painless Cautery.—It is said that a saturated solution of nitric acid and muriate of cocaine makes a painless cautery. In our hands the solution causes some pain, but little. It is strange to contrast the effect of the cocaine applied previous to the application of the acids and when it is used combined with the acids. In the first case it will require four or five minutes to get its physiological effect, and in the last we have the instant effect of the cocaine.—*Alabama Medical and Surgical Journal.*

A Peculiar Form of Dropsy.—Dr. M. Pargamin writes, in the *Russkaya Meditsina* of April 27, 1886, that he was called to see a young woman who was said to have dropsy, which the brother thought she had caught from one of his fellow-workmen who was suffering from a similar affection. On examination, it was found that the woman was in labor, the child presenting by the arm. Dr. Pargamin turned and delivered, but the abdomen was still much distended, and it was not until two more infants appeared that the dropsy was definitely cured.

Righteous Indignation.—A writer in an exchange thus introduces some eloquent and forcible remarks on a case of abortion which had come to his knowledge: "The low muttering thunders of destruction and roaming blizzard of the birth-strangled babe have just swept over our sister city, Atlanta, and now begin to disturb the gentle zephyrs of the Magic City."

A Memorial Hospital in Albany.—Mrs. Leland Sanford has purchased a piece of land on Washington Avenue, Albany, adjoining the site of the old Lathrop mansion, and, it is stated, will erect on it a handsome and well-appointed hospital for old men and women, as a memorial of her parents.

Scarpalogy.—This is the latest science which has come to rival palmistry, and is the art of reading a man's character by the shoes he wears, or, rather, by the way in which he wears them. One of its exponents recounts, in a French journal, *La Graphologie*, some of the axioms of the art. If the heel and sole of the shoe are worn down evenly, the owner is a good business man, energetic and quick to decide. If the outer side is most worn, the wearer is fond of adventures; while, if the inner side is most used, he is of an irresolute and rather weak character. Other traits of character, both good and bad, are equally clearly and infallibly expressed by the under side of the shoes, and the writer claims that he can read a man's disposition better in this way than by his handwriting. His soul is, as it were, pictured by his sole.

Carbolic Acid in Whooping-cough.—Dr. W. T. Cory has recently recommended again carbolic acid in whooping-cough. Dr. C. W. Suckling (*British Medical Journal*) believes, from his experience with it in twenty-three cases, that it is almost a specific. He gives the glycerine of carbolic acid in mint-water.

Dr. George W. Dewey of Moberly District, Mo., thus forcibly descants on some of the delusions of the day: On Gynecological delusions, the first gynecologists we read of lived in Judæa early in the Christian era. They got stuck on a Uterine Polypus of twelve years' standing. They took all the money a poor woman had, but failed utterly to cure her.

> As yet the doctors had not come
> To use the duck-bill speculum,
> Nor douches up vaginas sent,
> Nor introduced sea-tangle tent.

. . . Every woman who enters the office of the gynecologist is informed she has a retroversion or an anteversion, or a prolapsion, or cervicitis, or a cellulitis, or laceration, or some other uterine malady, and that to make a correct diagnosis, and to apply treatment, she must at once assume the classic genupectoral or Sims position. No sooner done than she is defloured by a Sims duck-bill. Not only married women but young virgins must submit to this deflourment. Not long since I was called to see a beautiful girl of sixteen summers, in whose countenance one could behold the *ne plus ultra* of virgin health, who informed me that for a slight pain in her back she had the day before called in a young gynecologist, who very gravely informed her she had "womb disease," and that it would be necessary for him to examine her with a speculum. She called on me to know if such damnable procedure was necessary. I told her I would as soon think of raping her. I advised her to keep her maidenhead, that it was a priceless jewel, and that such an examination was wholly unnecessary, and was proposed solely to gratify the idle or lecherous curiosity of a fool. . . . But once in a practice of forty years have I deemed it necessary to make a vaginal examination of a maid, and then it was in consultation with my friend Dr. Martin. The patient was a blushing maid of sixteen summers—a blackberry blonde. Her ancestors came originally from Zanzibar. She had a vaginal discharge, and as there was some doubt about its nature and cause, we very hesitatingly proposed a vaginal examination, to which she with much reluctance finally consented. Our diagnosis was gonorrhœa! . . . Our daily papers are filled with cuts and advertisements gynecological. Every reading lady of fifteen is posted on flexures, prolapsions, and "female weakness." A bitter wail comes up from New England that the native population are becoming extinct. Syringes, sponges, and womb-veils will exterminate the descendants of the Mayflower. The quidnunctious Yankee woman is posted in gynecology. She never breeds. The next decade of aggressive gynecologists will demand a gynecological chair in our female colleges, the business of which will be to teach young ladies how to avoid conception.

SUPRA-PUBIC CYSTOTOMY; EXTRACTION OF LARGE CALCULI; CORROSIVE SUBLIMATE POISONING.

BY WILLIAM T. BELFIELD, M.D.,

GENITO-URINARY SURGEON TO THE COOK COUNTY HOSPITAL, CHICAGO.

MAY 29, 1886, I saw, in consultation, M. B——, seventy years of age, who for nine years had suffered from a cystitis of steadily increasing severity. Eight physicians in various parts of the country, who had successively treated him, had agreed that the cause of the cystitis was prostatic enlargement; several surgeons had sounded him for stone with negative result, the last examination having been made under chloroform last year.

The patient was found emaciated, feeble, practically bed-ridden; urinating by catheter every half-hour or oftener, day and night; complaining of constant pain, aggravated by bodily movement, above the symphysis, in the rectum, and especially around the navel. He had been long in the habit of using morphine; for over two years had been unable to empty the bladder, except by catheter. The prostate was much enlarged laterally as well as vertically, but was smooth and symmetrical; the urine contained much pus and some blood. These symptoms indicated a vesical calculus as well as prostatic enlargement; though I supposed, from the negative results of exploration by his former medical attendants, that the stone was probably small, and either encysted or ensconced below the projecting prostate. (In three cases I have, upon digital exploration of the bladder, found thus concealed small calculi, which the sound in my own and other hands had failed to detect.) The patient was so convinced, by previous examinations, of the absence of calculi that he refused permission to use the sound; but he was anxious to have an attempt made, at any risk, to relieve the prostatic obstruction, which he had been taught to regard as the cause of his agony.

June 7th, with the assistance of Drs. Miller, Schaefer, and Randell, I undertook supra-pubic cystotomy for the purpose of removing, by galvano-cautery, that portion of the prostate which I assumed projected into the bladder. As soon as the patient was etherized I, for the first time, introduced a sound; it immediately became apparent that the bladder contained a large calculus. Having injected into the bladder seven ounces (all it would hold) of boracic acid solution, I made the usual incision down to the bladder and upon the point of a sound which then emerged through the vesical wall. At this stage much difficulty was experienced and time expended in the effort to enlarge the incision, the greatly hypertrophied bladder clasping the sound most rigidly; finally the wound was enlarged by the finger-nail.

The finger in the bladder found a median prostatic tumor about one inch in breadth, and projecting nearly an inch into the vesical cavity; behind and below this lay a calculus of about the size and shape of a walnut; adherent to the fundus was a second stone, a triangular prism in shape, 1½ inch long and 1¼ inch broad. Several attempts to extract the first stone failed on account of its size; it was therefore crushed and the fragments removed. The second stone, after resisting efforts at crushing, was with much difficulty extracted entire. The patient was by this time so collapsed—having been under ether more than an hour—that I deemed it unwise to prolong the operation, and abandoned the removal of the prostatic projection, which could have been accomplished without great difficulty. A drainage-tube was inserted in the lower angle of the wound and a soft catheter in the urethra; as the edges of the wound had been much bruised by the extraction of the intact calculus, no sutures were inserted.

Next day the temperature was 100.5° (the highest observed) and pulse 108; on the third day the temperature was normal and so remained, with slight variations. The wound was irrigated once daily with a bichloride of mercury solution, one to one thousand, and the bladder washed with a boracic acid solution.

Progress was favorable until the eleventh day, when there began a severe diarrhœa with rectal pain and tenesmus. Under camphor and opium slight improvement was noted. Two days later patient complained of a strong metallic taste, and the stools were slightly tinged with blood. It was not until then that the probable significance of the symptoms—sublimate poisoning—occurred to me, and that the use of the solution was discontinued.

Diarrhœa persisted, and was now accompanied with severe pains in the rectum and abdomen; the pulse became more rapid and feeble, and the patient was evidently failing. A week later (about the twentieth day after operation) a decided improvement in both local and general symptoms began, and became so decided that strong hopes of ultimate recovery were again entertained. At the beginning of the fifth week, however, diarrhœa and abdominal pains again became severe; the patient, though never vomiting, resolutely refused food because of the nauseating metallic taste; he rapidly sank, and died July 13th, the thirty-sixth day after operation.

As no autopsy was permitted, I was enabled to make only a hasty examination of the abdominal contents and to secure the bladder and kidneys. The peritoneum was normal, free from all traces of inflammation recent or old; there was no suppuration in nor around the bladder. The vesical wall was about five-eighths of an inch thick; the mucous membrane healthy except for a few small ecchymoses; the kidneys and their pelves were normal; under the circumstances the intestinal canal could not be examined.

Although no other case of sublimate intoxication through irrigation of wounds has come under my observation, yet a perusal of reports in current literature leaves little room for doubt that such intoxication existed in the present case; in how far it contributed to the fatal result, and to what degree this termination was due to senile exhaustion, may be debatable questions. The factor which so often causes death after (perineal) operations on the hypertrophied bladder—cysto-pyelitis—was certainly absent.

The calculi weighed two ounces and six drachms.

612 OTERA HOUSE BLOCK.

DR. WHITESIDE HIME, who lately delivered an address on "Pasteur and Protective Inoculations against Zymotic Disease," at the Royal Institution, is reported to be suffering from a wound inflicted in performing a post-mortem examination upon a dog which had died from rabies. He has gone to Paris to place himself under the treatment of M. Pasteur.

TWENTY-ONE CASES OF "TOY-PISTOL" WOUNDS, WITH A NEW METHOD OF TREATMENT.

By CHARLES A. POWERS, M.D.,

SURGEON TO OUT-PATIENTS, CHAMBERS STREET HOSPITAL, NEW YORK.

DURING the month of July of every year the daily press chronicles the death of a varying number of children from wounds produced by the "toy-pistol;" two such deaths have come to my knowledge, the present year, from professional sources, and I have read of many more in the daily papers; and while the mortality doubtless forms but a small percentage of the entire number of cases, it is yet sufficiently great to attest the danger which attends this class of injuries, and to demonstrate the importance of special care in their treatment.

These wounds are inflicted at very short range, and may be produced by an ordinary pistol from which is fired a blank cartridge, usually of .22 calibre, or by a smaller weapon upon which a cap is exploded. In the former the wound is made by the wadding of the cartridge, in the latter a piece of the cap is blown into the tissues.

In the cases presented herewith no distinction is made regarding the weapon used, though in the majority of the cases the injury was due to a wad from a blank cartridge; in no case was a bullet the source of trouble.

In by far the greater number of cases the palm of the hand is the seat of injury, and this rationally accounts for the attendant mortality: a foreign body is lodged beneath the palmar fascia, and, as a septic focus, may rapidly occasion cellulitis, and, possibly, septicæmia or pyæmia. In the newspaper reports above mentioned tetanus was generally given as the cause of death; its danger in palmar wounds is too well recognized to need comment.

During the ten days immediately before and after July 4th of the present year, twenty-one patients sought treatment at the Out-patient Department of the Chambers Street Hospital for wounds produced by the "toy-pistol." One of these, a boy, twelve years of age, had received a wound of the hand between the index and middle fingers six days previously, and had been treated by a physician, though the method of treatment was not ascertained. When first seen the hand was the seat of diffuse cellulitis, greatly swollen, hot, painful, reddened, brawny, and œdematous; the wrist and forearm were commencing to swell, the epitrochlear and axillary lymphatics were enlarged and painful. The discharge from the wound was scanty and ill-conditioned. Constitutional symptoms were limited to anorexia, headache, and general muscular weakness.

He was etherized, the wound enlarged and explored to a depth of one inch and three-quarters, but at that time no foreign body could be found. Free incisions were made on both palmar and dorsal surfaces of the hand, and compresses wet with a two and a half per cent. solution of carbolic acid were applied, and frequently changed.

The original wound was stuffed with the wet gauze, and on the eighth day a large wad was discharged from it. The cellulitis quickly disappeared, the wounds gradually closed, and on the twenty-eighth day he was discharged with a perfect result.

The remaining twenty had been hurt but a short time before they came under observation. They were all males, and the average age was eleven years. In fourteen cases the wound was situated in the palm of the hand or in the cleft between adjacent fingers; in three cases a finger was the seat of injury; and in one each the upper eyelid, the abdominal wall, and the gluteal region. The wounds varied in depth from one quarter of an inch to two inches.

In all of these twenty cases the following plan of treatment was adopted and thoroughly carried out: The parts about the wound were well cleansed with a solution of the bichloride of mercury—one part in one thousand—a free incision made at the site of the wound, as nearly to its bottom as seemed practicable, foreign bodies removed if they could be found, the wound itself thoroughly washed out with the bichloride solution, and loosely packed and dressed with compresses wet in the same.

In most of the cases the sides of the wound were blown full of powder, and for the first few days the discharges were markedly blackened by this.

The dressings were changed daily, and at each time the wound was well syringed out with the sublimate solution, in some instances wads or pieces of cap being washed away. When the discharges assumed a healthy appearance, the wound was dressed with the balsam of Peru.

The wounds healed kindly, and, on an average, were completely closed in sixteen days. In one case—a deep wound between the thumb and index finger—there was moderate reaction in the surrounding tissues the first day; but this went down within twenty-four hours, and it was the only complication of any kind whatever. In no case was there septicæmia, tetanus, or even cellulitis, and in every case the result was in all respects perfect.

This, then, seems to me to be the proper, and, in fact, necessary way of treating these toy-pistol cases: Scrupulously to cleanse the surrounding parts with an antiseptic solution of sufficient strength, make an incision at the site of the wound of such extent and to such depth that the discharges may have free exit, wash the wound out antiseptically, drain it, and let it granulate up from the bottom.

Of course one would avoid the palmar arches, or other important structures. Pain is prevented by the injection of a few minims of a four per cent. solution of cocaine, and a small brush will be found useful in thoroughly cleansing the bottom of the wound.

It was noticeable that in most of the cases of palmar wound the hand was in the position of the *main en griffe* when the patient first presented himself, and it retained that position for one or two days. It must have been due to a reflex paralysis of the interossei muscles, for it was independent of any direct injury to the ulnar nerve.

REMOVAL OF THE UTERINE APPENDAGES.

NINE CONSECUTIVE CASES.

By MARY A. DIXON JONES, M.D.,

GYNECOLOGIST TO WOMAN'S HOSPITAL OF BROOKLYN, N. Y.

CASE I. *Fibromyomata; chronic salpingitis; enlarged and cystic ovaries.*—Y. D——, aged thirty-five; married thirteen years; two children, youngest seven years of age; no miscarriages. Menstruation commenced at the age of thirteen; menorrhagia. When eighteen years of age, menstrual more frequent, lasting longer terms, and accompanied with pain; sometimes only one week in the four was free from the flow. Her general health began to suffer, for which she was given various tonics.

I was called to see the patient March, 1885. She was then very anæmic, weak, and prostrated, and there was mental depression; pulse full, and a temperature varying from 99° to 99½° F. On examination I found two subperitoneal uterine fibroids; uterus measured four inches in width, and its hard, irregular surface left no doubt that there were intramural growths. The cervix was lacerated, perineum ruptured, and the uterus had a tendency to sink down into the lower part of the pelvis, thereby interfering, to some extent, with the functions of the rectum and bladder.

This condition of the uterus, with the accompanying hemorrhages, was no doubt the cause of her suffering and ill-health, and though fibromyomata may be regarded by some as harmless and seldom fatal,[1] yet the complications in this case would certainly lead to some disastrous re-

[1] "Relatively few of them are fatal." (Pepper's System of Medicine, vol. iv.).

sult.[1] Her cachectic appearance and the low grade of constitutional disturbance suggested the possibility of some inflammatory action, or even the possibility of carcinomatous or sarcomatous degeneration.[2]

But whatever were the conditions of the patient, she must be relieved if possible. Her system seemed now on the limits of its capability of endurance, the tumors were evidently increasing in size, and might at any time cause dangerous pressure or fatal hemorrhage. The question was, what was best to be done. Should we commence using ergot, with the vague hope of somehow having good results? Would the sub-serous tumors and the interstitial fibroids be favorably affected thereby? Could we be justified in placing her for months under the influence of ergot, risking the dangers of abscesses and ergotism? Would she live to stand the long and uncertain experiment? And were we not equally uncertain of any good result?[3]

Should we try the various "sorbefacients," iodides, bromides, and chlorides, which are said to have the power of removing these neoplasms?[4] I could not believe this would be of the least efficacy, and their long-continued use would only derange an already enfeebled stomach, and still more impoverish an already impoverished system.

Should we try electrolysis, piercing the tumors with long electrolytic needles? Such a proceeding in this case would be attended with grave and unusual dangers. Should we remove the sub-serous tumors, according to Schroeder's method of partial hysterectomy? The operation is extremely dangerous, and, even if successful, there would still be the interstitial fibroids, which probably were making most of the trouble. Enucleation and traction have had brilliant results in the hands of two of our eminent American gynecologists, yet, with our present advance in surgery and improved methods of operating, hysterectomy seemed less appalling and less hazardous, and would more fully meet all the indications in this case.[6]

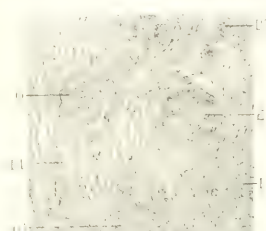
There was left for consideration either hysterectomy or removal of the uterine appendages. In the present state of the patient, a necessity for the former operation would be unfortunate, and the uterine appendages were so diseased that *their* removal was a necessity.[6]

I decided to do either hysterectomy or Tait's operation, as would be best for the patient. May 19, 1885, the patient was received into my private hospital, and on May 23d I performed the latter, assisted by Dr. C. C. Lee, Dr. C. N. Jones, Dr. S. King, and Dr. J. C. Minard. The condition of the uterus was well examined, and it was deemed advisable to remove only the appendages. There was considerable difficulty in securing a pedicle. The ovaries were three times their normal size, and projecting from each one was a cyst the size of a hen's egg. It seemed almost a question whether we were operating for cystic ovaries or for a fibroma.

The patient slept well the night after the operation; next day took some nourishment; sixth day ate solid food with relish. Temperature, 98⅗°; pulse, 70. Eighth day, stitches removed; abdominal wound entirely healed. On the twenty-fifth day after the operation she was discharged from the hospital well, and walked four blocks that morning without any discomfort. She has continued to grow strong, and has been in excellent health ever since, has gained in flesh, is active and vigorous, and says she has not been as comfortable or as well since she was a girl. The size of the tumors are gradually diminishing.

Macroscopical examination: The tubes are long and tortuous, the ovaries are enormously enlarged, and on their surface exhibit numerous cicatrices. On section the structure is dense and fibrous, and enclosing numerous cyst cavities.

Microscopical examination:[7] Both ovaries are in a state of chronic ovaritis. All the special ovarian tissue



[illegible] I, groups of inflammatory corpuscles of recent date [illegible] ovum, coarsely granular; E, ovum split up [illegible] O I, ovum split up [illegible] to epithelia and inflammatory corpuscles.

is replaced by dense fibrous connective tissue, coarse fibres interlacing. The left ovary in its cortical portion exhibits nests of inflammatory corpuscles, which shows that the morbid process in portions of the ovary is subacute. In the cortical substance of the ovary are still left a few small ova, and it is interesting to trace out under the microscope the manner in which the ova are destroyed. We could also see groups of epithelia, when an ovum had been split up into its constitutional elements; still other groups gave a cluster of partly epithelial and partly inflammatory corpuscles, which latter had arisen from the epithelia. Such inflammatory corpuscles mixed with those arising from the connective tissue and the smooth muscle-fibres, showed the formation of cicatricial fibrous connective tissue.

CASE II. *Chronic [illegible] ovary; salpingitis.*—Miss L. M——, single; thirty-five years of age. Menstruation commenced at the age of

[1] "Fatal results by no means infrequent" (Meadows' Brit. Gyn. Journal). "Uterine myoma is fatal in a much larger number of instances than is generally supposed" (Tait, Brit. Gyn. Journal). "The gravest [illegible] hemorrhages, mental depression and anxiety, and disturbance of the functions of nutrition and excretion, which usually drag the patient down to the grave" (Thomas, p. 654).

[2] "I have had several instances under observation where the tumor of a simple fibroid rapidly underwent the metamorphosis into sarcoma (Emmet, p. 545). "The weighty authority of Virchow is cast into the scale favoring the possibility of sarcomatous degeneration" (Thomas).

[3] "Much harm has resulted from the injurious use of ergot" (Emmet). Thomas says he has known many fatal cases of sloughing when the rigidly contracted os prevented a resort to surgical procedures. "The moment the treatment ceases the hemorrhages come back as violently as ever" (Lawson Tait).

[4] "It is not possible by therapeutical means to obtain a sensible diminution in the volume of a real fibrous tumor" (Scanzoni). "We have never obtained any sensible results from the internal exhibition of iodine" (Scanzoni). "Medical treatment is worse than useless, it is a mere waste of time; I would say, scarcely honest" (Meadows' Brit. Gyn. Journal). "I very much fear that no remedy exists that will exert any influence on the growth of these tumors, or cause their absorption" (West and Duncan). "We know of no means whereby they can be made to disappear short of a surgical operation" (Hewitt, op. cit., p. 569). "No such effect can be looked for with any confidence" (Thomas). "We are to-day ignorant of any means, other than extirpation, by which a hard fibroid can be removed from the uterine tissue" (Emmet, op. cit., p. 566). "I have never seen a single instance, nor an approach to one" (Tait, May 27, 1885). "The medical treatment of uterine fibroma is a myth" (Lawson Tait).

[5] "I have seen several deaths occur from it in this city" (Emmet). "The profession has not generally consented to the adoption of this measure as safe and efficacious" (Pepper's System of Medicine, p. 270, vol. iv.).

[6] "The results of enucleation (interstitial fibroids) are by no means encouraging. We class the operation among the most hazardous in surgery" (Diseases of Women, West and Duncan). "It really deserves, as far as I am concerned, the appellation of the word butchery" (Lawson Tait, Brit. Gyn. Journal). Emmet says: "In this city alone three deaths have occurred from perforation by the hand of three different operators when dexterity could not be questioned" (Op. cit., p. 607). Dr. More Madden, before the British Gynecological Society, speaks of the "*less heroic measures*, such as enucleation and removal by traction," and says: "I think the operation of enucleation, which is really a very simple operation, and which has been very successful in my practice, is preferable in suitable cases. By this operation I have removed not only large submucous fibro-myomas, but also interstitial, and in some instances partly sub-serous, tumors." One case he reports: "Uterus retroflexed, hollow of the sacrum occupied by a large globular interstitial tumor, as large as a fœtal head at the seventh month." The uterine cavity was laid open and the uncertain instruments were plunged in, pulling forth the tumor. "A large coil of intestines followed," as if to know whether he so unkindly knocked or no. The instruments were in the peritoneal cavity! Now able to see what was the injury, how to repair it, or how to clean the cavity. The patient was in collapse, but fortunately recovered. The second case he reports: "Uterus completely retroverted, a considerable-sized tumor was found bulging into the uterine cavity. The most prominent portion of the tumor was firmly grasped by the vulsellum and forcibly dragged down through the os, and as far as possible into the vagina; and the growth was thus cut away. In this way we had removed more than two-thirds of the growth when the patient became collapsed. On the second night after the operation she again became collapsed, sank and died." As I see it, a carefully and well-arranged hysterectomy is less dangerous, and gives a more intelligent chance of saving life. About the time of my operation, or just before, I had the pleasure of witnessing Dr. C. C. Lee perform hysterectomy, at the New York Woman's Hospital, for an immense cystic fibroid of the uterus. The operation progressed pleasantly, and the patient made an excellent recovery

[7] The microscopical examinations were made in Dr. Heitzman's laboratory, part of them by Dr. Mary D. Jones and part by Dr. C. N. D. Jones.

thirteen; severe pain the first time, and she has never passed a period since without great suffering, the pain always commencing three or four days before the flow. The flow now lasts four or five days, not as long as formerly, nor is the flow as great, but the pain is constant and unremitting, so severe at times she can neither walk nor stand. She also states that her first attack of serious illness was fifteen years ago, when she was taken with a hard aching pain in the left side of the pelvis, which increased gradually year by year, ofttimes preventing her from sleeping, and frequently so sharp and lancinating that she had to scream with the agony. For this suffering she consulted many physicians, and had a great variety of treatment; some prescribed fly-blisters to be repeatedly placed over the lower part of the abdomen, and leeching at intervals; some used pessaries which she said "always made her worse;" for nine months she was treated for "inflammation and misplacement," with no relief; a year she was treated for "ulceration," no better results; for five years she was treated for "uterine congestion." The next physician, after attending her for some time, said he could do nothing more, and relieved by hypodermatic injections of morphia. Her last physician treated her for valvular disease of the heart; said the uterus was misplaced and bound down by adhesions. He also attempted to introduce pessaries, which, as before, "gave great distress."

The patient first called to see me May 5, 1885. I found the uterus acutely anteflexed, not adherent, ovaries small, tender, and exceedingly sensitive. The patient was extremely nervous, hysterical, and her mental condition somewhat disturbed. Many of her friends said "she was not exactly right in her mind." But I considered all these abnormal nerve symptoms due to reflex irritation from the condition of the ovaries, and informed the patient that an operation for their removal might be necessary.

I did not see her again for more than a month, and on examination found the same conditions I had previously diagnosed. The patient informed me that she had made efforts to get into a hospital, but had not succeeded. First applied to the Homœopathic Hospital in New York, was examined by the visiting surgeon, but not admitted. Next applied to a hospital in Brooklyn; after a consultation of the staff, she was informed that she was incurable, and the hospital did not receive incurables." I told her I would admit her in to my private hospital, give her any necessary treatment, and perform for her any operation that might be necessary for her recovery. The next day, June 18th, she entered. I had her immediately put in bed, kept quiet, good nourishment. Massage twice daily, bowels freely open, hot douches daily, and the skin kept active by warm baths and rubbings.

June 25, 1885, I performed laparotomy, assisted by Professor Wylie and Dr. C. N. D. Jones. Dr. S. King gave the ether; the ovaries and tubes from each side were removed. The next day her temperature was 101°, pulse, 98. On the fifth day she asked for beefsteak and toast for breakfast, and on the eighth day the sutures were removed from the abdominal walls, when the wound was found entirely healed, and on August 1st she was discharged from the hospital apparently well.

Macroscopical appearance of specimens: Both tubes are dilated; the left at one portion is dilated into a sac 2 ctm. in diameter, and at the fimbriated extremity the lumen is obliterated by inflammation. Both ovaries are smaller than normal, and contain numerous small cysts.

Microscopical examination: Section from left ovary gave a rather startling appearance; there were numerous comparatively large alveoli, or closed places, filled with a tissue endothelial in nature; the alveoli were surrounded by and closed with coarse fibrous connective tissue, richly supplied with blood-vessels. This connective tissue penetrated the alveoli, remaining fibrous in character, and produced elevations which were surrounded by endothelial tissue. The boundary line between the connective tissue and the endothelium in most places was sharply marked, in other places the two tissues blended without any definite line of demarcation. The endothelial tissue consisted of globular and polyhedral corpuscles, mainly arranged in rows, and freely intermixed with dark brown fat- and pigment globules. The rows of corpuscles are in many places interrupted by light gaps, probably caused by a liquefaction of these corpuscles. This tumor we would have to term either an endothelioma or an alveolar sarcoma

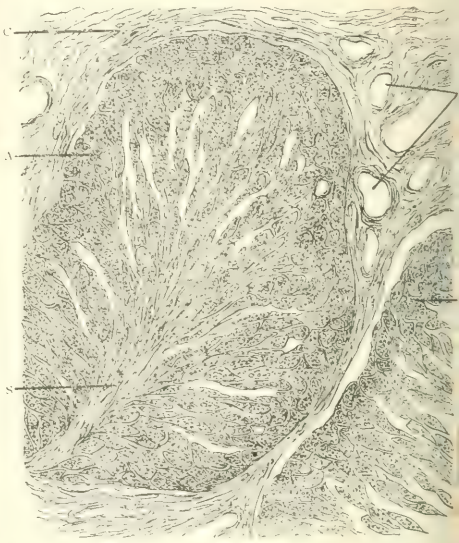


Fig. 3.—C, coarse fibrous connective tissue, with large blood-vessels; V, main venous in character; S, septum, or prolongation of connective tissue into a close space filled with globular and angular corpuscles in rows. Between the rows there are fat-globules and empty slits. A, cellular elements.

Right ovary contains cysts filled with an albuminous liquid. The arteries of the medullary portion are tortuous in a high degree, and their middle coat in a marked waxy degeneration; the stroma everywhere is transformed into dense interlacing connective tissue, the result of chronic ovaritis.

Many persons thought the patient could not survive the operation; but since it was performed she has been constantly gaining in strength and vigor. She looks well and her nerve conditions are improving. October 10, 1885, she called to see me, and said she had gone to church three times the previous Sunday—walking.

Case II. *Chronic pelvic peritonitis; pyo-salpinx ovaritis.*—H. J——, a frail little woman, aged twenty three years, weight seventy-five pounds, called to see me August 18, 1885. She has been married two years and eight months. Menstruation appeared at the age of twelve; no pain at first, but soon after she had dysmenorrhœa, which gradually grew more and more severe, and the menstrual flow more profuse, continuing eight or nine days. A year after marriage she gave birth to premature child, seven and one-half months, which lived only a few days. After childbirth she had a severe attack of septic peritonitis, which lasted eleven weeks; since which time she has not been able to go around constantly in bed, says the slightest exertion prostrates her, that she "suffers constantly with pain and soreness in the pelvis; sharp piercing pains darting and shooting up through the rectum, not a day that she does not feel these piercing pains, frequently many times during the day; that for seven years she has suffered thus, had ever

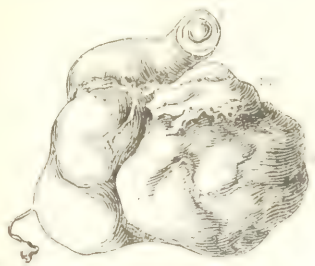
thing put on to draw the inflammation out:" now, she says, "she is willing to go through anything for the sake of being well." Her temperature and pulse were 99½ and 100 respectively.

I examined the pelvic organs, and found the cervix lacerated, excessive tenderness in the region of the ovaries, tubes enlarged and evidently fixed by firm adhesions.

At once, there seemed to be no other way of relieving her sufferings or curing her than by the removal of the uterine appendages. Still, while preparing her for the operation, I determined to see if treatment could not, according to the statement of some, cure her, and so supersede the necessity of an operation; for if anyone should be saved the dangers of an operation it was this frail, feeble little woman. One of our most distinguished gynecologists says some cases of tubal and ovarian disease can be cured by repeated applications of Churchill's tincture of iodine, hot douches, etc. I tried faithfully these, and, as I thought, all other recognized and approved means. The patient was in my private hospital, and everything was constantly done to improve her special and general condition. Her health grew better, and she seemed much improved in many respects, there was less peritoneal inflammation, the adhesions stretched and softened, yet, after all these three months of persistent and careful treatment there seemed to be just as much soreness and tenderness about the ovaries, the tubes seemed to be even more enlarged and prominent, the darting pains just as severe and frequent, the movement of the bowels just as painful, and the patient no more able to be out of bed. There was now as much necessity for the operation as there was three months previously. Her life was in peril without it. The patient was anxious and impatient for it to be performed; many times when other patients were to undergo operations she would wish it was her; often said, "she wanted her ovaries taken out." October 29th we commenced to prepare her especially for the operation, and on the 31st it was performed. I made the usual incision of two and one-half inches, the abdominal walls bled freely, and there was great difficulty in getting out the appendages on account of strong adhesions. Both tubes were firmly adherent by their extremities, and throughout their whole extent to the ovaries, and were very much dilated and filled with fluid. Their transparent attenuated walls seemed ready to burst. The pedicle on each side was firmly secured, appendages removed, and the peritoneal cavity washed out, but there was so much, and such continued oozing that a drainage-tube was put in. At 9.30 same evening, temperature 101°, pulse 130; fifth day, temperature 99½°, pulse 100. The tube was repeatedly washed out and the dressings changed, considerable bloody serum oozed out. On sixth day glass tube was removed and a small rubber tube inserted in its place. Eighth day, sutures removed; the patient seemed well, temperature and pulse almost normal, appetite good, and she *relieved of the pain* from which she had long suffered, yet the fistulous tract did not heal; there continued to be a small sinus from which constantly issued a slight discharge.

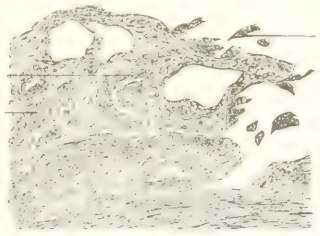
One day, some two months after the operation, as I was pressing the sides of this fistulous canal to see the quantity and nature of the discharge, there burst out a small white mass, which, upon examination, proved to be the ligature of one of the stumps—there was the Staffordshire knot exactly! The lower end of the drainage-tube had in some way become displaced toward the right side; probably in this way the ligature had become ejected and was consequently expelled. Soon after the passage of this ligature the fistulous tract healed, and there was no further trouble.[1]

May 20, 1886, her husband writes that she is feeling splendidly; that he could not have imagined that she ever could be as well. May 30th, she wrote: "Doctor, you have given me my life, and what is more, an interest in life."



tube firmly attached to the ovary.

Microscopical section of the left ovary revealed the presence of rather dense fibrous connective tissue, interlaced with small bundles of smooth muscle-fibres; follicles scanty. Ovary has the appearance of senile involution (M. I.). Microscopical section from the right ovary exhibits acute inflammation, arteries dilated and extremely tortuous (C). The tubes were in a state of chronic pyosalpingitis.



When we examine these structures we see how completely their physiological functions were destroyed. Even if we had aspirated the tubes, and so drawn off the pus, the ovaries were so diseased, the lining membrane of the tubes so changed, and there was such a desquamation of the epithelii, that there could not possibly have been any true functionating power. And the aspirating or opening and draining would have been as dangerous as the operation for removal, and there would still have been left the diseased structures to give trouble and distress, and be a cause of serious complications.

By this operation (Tait's) many cases can be restored to health who must otherwise suffer and die. I can now look back upon a practice of years, and remember many whom I could have cured if I had known of this operation at the time.

Case IV. *Chronic ovaritis; Abscess of left ovary; Pyo-salpingitis*—Mrs. D——, a delicate young woman, twenty-one years of age, married two years, no children; menstruation commenced at the age of thirteen, from the first it was accompanied with great pain, the pai commencing two or three days before the flow. After marriage dysmenorrhœa was much increased; she had an attack of gonorrhœa, which inflammation and infection extended through the tubes, causing inflammation so severe that she had to keep her bed the most of the time. When first seen by the writer she had been confined to her bed for some weeks, the whole pelvis was sore and tender, on each side of the uterus was a mass low down and extremely sensitive. In appearance the patient was small and imperfectly developed, there was no breadth or depth to the pelvis, and an apparent lack of

[1] Last October McBurney, of New York, performed the radical operation for hernia, using six silk ligatures; three remained two sinuses. On April 9th, in letting down he found the ligatures had not been absorbed. March 26, 1886, Dr. N. D. Jones performed same operation for an enormous hernia. A small fistula remained. May 20th the wound was opened in the line of the old cicatrix and the unabsorbed ligature removed, after which the wound healed rapidly.

vigor in every organ. She was removed to my private hospital, November 11, 1885, not able to sit up, had a quick, feeble pulse and a high temperature. She was placed immediately in bed, and had constant care day and night. By treatment the size of the mass was reduced, adhesions softened, and much of the sensitiveness relieved. The patient in every respect seemed in a very much better condition, had a good appetite, was able to be around, and was feeling comfortable. Some would have pronounced her "cured without an operation," but we knew the causes were still existing, ready to give trouble at any time.

The patient was very anxious that the diseased structures should be removed, though in some way she became fully impressed with the idea that she would not live. January 23, 1886, I performed the operation for the removal of the appendages, assisted by Dr. W. G. Wylie and Dr. C. N. D. Jones. Dr. Ingals administered the ether. The ovaries were large and adherent. Right ovary was first removed, it measured 2½ inches; the left one measured 3½ inches. In lifting the left ovary an abscess in the ovary burst, discharging a thick, greenish-yellow pus, some of which escaped into the peritoneal cavity. The cavity was well washed out, but the continual oozing from the broken adhesions made it necessary to put in a drainage-tube. For a long time after being placed in bed the patient seemed to be in a condition of extreme surgical shock, which lasted some hours. Her external surface was cold and clammy. Two attendants continued rubbing her for more than an hour before reaction was fully established. Her pulse continued to go up, and by next morning it was 170 per minute, and soon grew so rapid that it could not be counted; temperature, 101⅛°. By 11 P.M. the day after the operation her pulse was again 170 per minute; temperature, 101½°. Tube was washed out. On third day at 8.30 A.M. her pulse was 160; temperature, 100⅕°. Pancreatized milk was given by the rectum. Fourth day—pulse, 120; temperature, 101⅝°. Nausea and vomiting still continued; at 9 A.M. vomited dark fluid; gave seidlitz powders; washed out the tube, no vomiting after. Up to this time she had taken ten seidlitz powders. They had produced no operation on the bowels, yet in some way they seemed to have the power of destroying or carrying off the microbes, and so preventing any septicæmia.[1] From this time the patient began to improve rapidly, and Saturday morning, a week after the operation, she looked brighter, better, and stronger than she had looked for months. Seventh day the glass drainage-tube was removed and a small rubber tube inserted in its place, which was removed at the end of another week, and before the end of the third week the opening was entirely closed and the wound healed. Twenty-second day after the operation the patient left the hospital, rode three miles to another part of the city, stepped lightly from the carriage, ran up high steps to the front door, then up a high flight of stairs to the second floor; said "she felt perfectly well; had not a pain or an ache." March 2, 1886, she wrote: "I am feeling perfectly well, never felt better in my life; have an excellent appetite, and am gaining in flesh."

The cause of suffering was removed, which, if allowed to remain, would doubtless have caused her death before many months.

Macroscopical examination: Left ovary very much enlarged, upper surface exhibiting an opening with jagged edges, which led into a pus-cavity three centimetres in diameter, fimbriated extremity of Fallopian tube dilated into a pus-sack. A vertical section through the ovary exhibits two follicles, and in the centre an abscess cavity, with irregular walls. In its vicinity and toward the outer periphery the tissue is discolored, soft, and friable, indicative of beginning suppuration.

[1] On the slightest indication [illegible] promptly acting purgative, it matters not what (Tait, in British Medical Journal, May 15, 1886).

Microscopical examination: A section from the vicinity of the abscess exhibits a marked infiltration of the tissue with inflammatory corpuscles. Both the myxomatous and fibrous connective tissue are transformed into inflammatory corpuscles to a considerable extent. The smooth muscle-fibres likewise are transformed into such corpus-

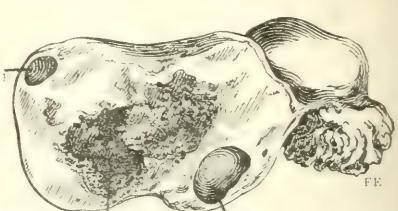


Fig. 1.—F, F, follicles; A, abscess cavity; FF, fimbriated extremity of Fallopian tube.

cles, and in many places rows of the corpuscles indicate their origin from smooth muscle-fibres. This transformation also invades the endothelium and the smooth muscle-fibres of the middle coat of the arteries, which near the apices appear to be completely destroyed. The cortical substance of the ovary not invaded by inflammation is of a marked myxomatous character.

The right ovary is in a condition of sub-acute inflammation. Portions of the medullary substance being transformed into dense fibrous connective tissue, other portions are crowded with inflammatory corpuscles.

Left Fallopian tube exhibits a marked inflammation and infiltration both in the mucosa and in the muscle-tissue. Right Fallopian tube is in a state of acute inflammation, both in the mucosa and muscle-coat.

Comparatively few cases of abscess of the ovaries are reported. In Scanzoni's work, p. 398, is recorded a case of abscess of the ovary; woman died suddenly from rupture of abscess into the peritoneal cavity. Emmet, in the last edition of his work, p. 651, says: "I have seen but one instance of this kind of ovary. A mass, the size of a hen's egg, was felt on left side. February 16th applications of pure carbolic acid was made to the fun-

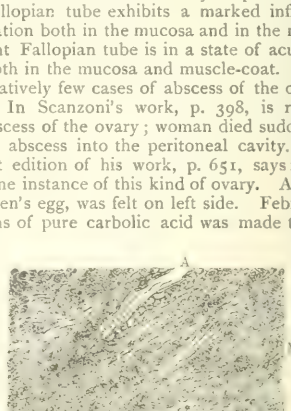

Fig. 2.—Superficial portion of [illegible] M, mass of inflammatory corpuscles originating from [illegible]; A, artery whose endothelial and muscle-coat toward the [illegible] completely transformed into inflammatory corpuscles; P, beginning formation [illegible].

dus daily by means of an applicator; 23d, sponge-tent introduced, canal dilated, granulations removed, and equal parts of carbolic acid and glycerine applied freely throughout the canal. March 25th, canal partially dilated to facilitate the application of carbolic acid. On 30th, when half awake, she turned suddenly in bed, when she felt something move inside of her, went into collapse, and died." From the autopsy, made five hours after death, the author says: "It was evident the ovary had long been the seat of an abscess."

Thomas, p. 667, quotes a similar case of collapse and death: "A blister had been applied on the hypogastrium, and opium given in large doses, five days after became collapsed and died. Autopsy eighteen hours after death; between the organs a great deal of puriform

serum; left ovary size of hen's egg; in its removal several ounces of pus escaped. No evidence of cellulitis."

Lawson Tait says, in his work on "Diseases of the Ovaries": "Abscess of the ovaries is a condition of extreme rarity, and in the majority of instances probably death occurs from the rupture of the abscess into the peritoneum. The only cases of abscesses of the ovary, in clinical experience of which I have been certain, are two." First case, op. cit., 61: "Left ovary contained two ounces of pus; both ovaries and tubes removed; patient recovered without a bad symptom." The second case, op. cit., 125: "Patient had suffered many years with great ovarian pain; much increased at the menstrual period; the left ovary contained two drachms of pus and appeared to be on the point of bursting into the abdominal cavity. Had it done so she doubtless would have died. Both appendages were removed, and she made a perfect recovery."

In the same work he quotes two cases that were reported in *The Lancet*, 1877. "One had an exploratory incision, patient died a few hours after; the other had an exploratory puncture, symptoms grew worse, and she died some months after." Tait remarks, "It is impossible to resist the conclusion that abdominal section, performed soon after the onset of serious symptoms, would have enabled the surgeon to have relieved his patient."

July, 1885, before the British Gynecological Society, Lawson Tait reported two cases of double pyo-salpinx together with abscess of right ovary. "The lives of both patients had been for months in jeopardy; the operations were of extreme difficulty; abscesses bursted; and very great care had to be taken in cleansing the peritoneum. The patients recovered" (*Brit. Gyn. Journal*).

April, 1886, Tait reports before the same Society another case of abscess of the ovary: "Operation extremely difficult and the hemorrhage severe" (*Brit. Med. Journal*, May 8, 1886).

Edis reported before the same society a successful operation for abscess of ovary.

As far as I have seen the reports, the only patients with abscess of the ovaries who have recovered are those for whom Tait's operation was performed.

Case V.—*Chronic ovaritis; pyo-salpingitis.*—Miss A. Y——, a young woman, twenty years of age, has suffered with constant pain in the pelvis for seven years, greatly increased at the menstrual periods, and at times extremely severe. But the most serious consideration in her case was the unhappy and abnormal manifestations of the nervous system, depression of spirits, and at times the contemplation of suicide. All of which symptoms I believed were largely due to reflex irritation from the thoroughly diseased condition of the ovaries and tubes. When first called to see her I found on examination uterus completely retroflexed and retroverted, both ovaries enlarged, sensitive, and dislocated down into the recto-uterine cul-de-sac. I made known to her her condition and the necessity for an operation. She at once accepted the idea and was impatient for the operation to be performed, frequently saying, "I want *both* ovaries and both tubes removed;" said that "for years she had suffered such distress and agonizing pain that she could stand it no longer."

She was by special and general treatment prepared for the operation. I removed the appendages from both sides of the uterus. She made an excellent recovery, and month by month she is growing stronger and more vigorous, her nervous system more and more normal, and she is enabled to enjoy life and attend to her ordinary duties.

Microscopical examination showed chronic ovaritis and pyo-salpingitis.

Case VI. *Hystero epilepsy; cirrhosis of the ovaries; salpingitis.*—Mrs. M. K——, aged thirty-six years. After the birth of the fourth child her health began to fail; great prostration, and suffering much with her back, constant pain and distress in the pelvis; and there was a history of gonorrhœal infection. The attacks of hystero-epilepsy were gradually growing more serious, her mind was becoming less active, and her perceptions more obtuse. Already her face had the dull, heavy expression of an epileptic. These epileptic attacks recurred at every monthly period; sometimes during the day she would have a continued succession of convulsions, with intervals of only a few minutes, struggling and throwing herself in all conceivable positions; frequently opisthotonus, and showing "le pied hysterique."

It was evident that these spasms or convulsions were caused by some internal irritation; and unless the cause was removed it was impossible for any medical treatment or appliances to help her, or prevent the recurrence of the spasms. Such cases usually tend to idiocy and death.

When I presented to her the hope of possibly relieving her by removing the diseased ovaries, she cordially accepted the idea, and on December 10, 1885, I performed the operation, in my private hospital, assisted by Dr. C. N. D. Jones. Dr. Cary gave the ether. Dr. J. L. Minard was present. The patient recovered well from the ether, and seemed scarcely sick during the whole convalescence from the operation; was up and around at the end of the second week. She has since done well in every respect, showing greatly improved nervous condition, and up to the present time, June 5th, has not had a return of the spasms, and the dull epileptic look is giving way to a more intelligent countenance.

Macroscopical examination: Ovaries small, hard, and nodular. When cut open they were markedly cirrhotic, composed entirely of coarse fibrous tissue, interlacing. Almost the whole gland-structure was replaced by cicatricial tissue. In the left ovary was seen the remains of only one follicle; in the right there were three, all of them located near the outer end of the ovary. The tubes were dilated into three cyst cavities and there were several small parovarian cysts.

Microscopical examination: Left ovary almost entirely transformed into dense fibrous connective tissue; no healthy gland-structure left. Right ovary, especially in its medullary portion shows, in some places, inflammatory infiltration, crowded with inflammatory corpuscles, while in other parts the ovarian tissue is transformed into dense fibrous connective tissue. The condition is sub-acute ovaritis. There is a marked dilatation and tortuosity of the blood-vessels, most of the arteries showing hyperplasia of the middle coat with marked waxy degeneration. The tubes are in a condition of well-pronounced salpingitis, both in the mucous and muscular portion. The tubal arteries show hyperplasia of the muscle-coat.

I conceive that nothing else would have relieved the spasms. No amount of bromides or massage—nothing but the removal of these diseased organs—organs which had organically changed in structure, which could no longer perform their functions, and hence were a source of irritation.

Case VII. *Salpingitis; ovaritis.*—M. S——, twenty-six years of age; married six years; two children, the youngest fifteen months old. She complained of great pain in her back, in her pelvis, and down her thighs, and so much bearing down, heaviness, and distress that she could not rest night or day; could not attend to her duties; was always tormented with this constant suffering. She had done everything to find relief. The cervix had been twice sewed up, the perineum had been restored, and lately the patient had spent seven months in a hospital, and the womb had been treated *ad nauseam*. Still her sufferings were just as great, as constant, and as continued. On examination I found the uterus completely retroverted, lips of the cervix gaping wide apart and covered with hard cicatricial tissue, the ovaries very tender and dislocated down into Douglas' cul-de-sac.

She entered my private hospital January 20, 1886. I sewed up the lacerated cervix for the third time, in hopes possibly of relieving some of her nervous symptoms, and as a little recreation to her while she should be prepared

for the more serious operation. Such was her nervous excitability that she had to be chained by some thought. I informed her that this operation would not relieve the great distress, and eight days after she pretty clearly informed me of the same fact; but the operation was an entire success, the wayward walls of the cervix were brought into perfect and easy coaptation, and there they will stay, a specimen of good workmanship! Wound healed by first intention.

The operation for the removal of the appendages took place February 10th. Present, Dr. C. N. D. Jones and Dr. Ingalls. Before the operation the husband informed me that "the desire for a family was nothing compared to the distress of seeing her constantly suffer." I know the mild-mannered man had groaned under her tantrums, and felt that he could not live with her and her two ovaries, too. The appendages were removed from both sides. The ovaries were atrophied, and had evidently been the seat of long-standing inflammation. Third day after the operation the patient was singing, and said she felt well enough to get up. As days passed on she perceived she was free from the old distress that had followed her for years. At the end of sixteen days she was discharged from the hospital, well.

I saw the patient May 6th. She was the picture of health; happy, cheerful, and active in her household duties; said she felt perfectly well, had no pain or distress.

Many suppose this operation renders a woman sterile, but we must bear in mind that she is already completely sterilized by disease. The operation takes away the cause of suffering, and enables the patient to lead a life of usefulness and activity, instead of suffering long years of invalidism.

Macroscopical examinations of specimens: Both tubes present an anomalous appearance. Each is lifted from the central portion outward, having two distinct sets of fimbriæ; the lumina of the twin tubes remain separate to the point at which they were severed from the uterus, and probably continued so until they communicated with the uterine cavity. The walls of the tube are much thickened, together with the meso-salpinx; in the latter there are numerous small cysts. The ovaries are small and atrophied. Nearly the whole portion of the left ovary is occupied by a large cyst.

Microscopical examination: Both ovaries are in a state of acute and subacute ovaritis, groups of inflammatory corpuscles mainly in the cortical portion. The arteries of the left ovary are in a state of waxy degeneration, and the stroma contains a large number of amylaceous corpuscles. Both tubes are in a state of acute salpingitis; both in the mucosa and muscle-coat there are groups of inflammatory corpuscles.

Case VIII. *Salpingitis; ovaritis; ovarian hæmatoma.*—Miss L. S——, aged twenty-three, has been suffering with pain in the pelvis for the last five years, very much increased at the menstrual period. Menstruation commenced at the age of thirteen. She suffered agonies, not only during the period, but for three or four days before; and for the last two years has been unable to attend to her ordinary duties.

She called to see me February 20th. On examination I found the uterus anteflexed and bound down by adhesions, and a large inflammatory mass low down on each side of the uterus. By treatment the conditions were very much ameliorated, and on March 27th she entered my private hospital, and on the 31st I performed the operation for removing the uterine appendages, assisted by Dr. C. N. D. Jones. Dr. Ingalls administered the ether. The abdominal walls bled profusely, and there was great difficulty in getting out the ovaries on account of dense and firm adhesions and extreme shortening of the broad ligament. She recovered nicely, with no drawback except unusual nausea and vomiting, probably due to chronic dyspepsia and an enlarged liver.

Macroscopical examination: The right ovary on one surface presents a ragged opening leading into a cavity three centimetres in diameter, which contains a large clot of blood, and is therefore the seat of a *hæmatoma saccatum.* The other portion is in a state of cystic degeneration.

In the left ovary there is *not the least vestige of normal ovarian tissue,* nor is there a single graafian follicle, or normal corpus lutea; the whole is occupied by an infinite number of small cysts, the larger of which is about one centimetre in diameter.

In the right ovary, stroma transformed into fibrous connective tissue to some extent, other portions occupied by inflammatory corpuscles; sub-acute ovaritis; waxy degeneration of the arteries; corpora amylacea.

Case IX. *Ovaritis; abscess of right ovary; chronic salpingitis; endo-arteritis (syphilitic?).*—M. B——, twenty-four years of age, unmarried. Menstruated at fifteen; before the appearance of menstrualin was subject to attacks of dizziness. The last five years she has suffered with almost constant pain in the pelvis, very much in creased at the menstrual periods, and for the last three years the intense pain has commenced a week before the flow, and continued during the period, being so sharp and severe that she has had to keep her bed lately most of the time.

She was sent Febraury 10, 1886, by one of the consultants to the Woman's Hospital clinic. On examination I found the whole pelvis exceedingly tender, the slightest pressure from the outside causing pain; the uterus was acutely anteflexed and the appendages drawn up by adhesive inflammation. While in the Woman's Hospital she was treated, the uterus dilated, etc., but the menstrual pain continued just as severe, and her sufferings just as constant. April 3d she was admitted into my private hospital, and on the 6th I removed the uterine appendages. There was great difficulty in the operation, on account of many and firm adhesions, and during the operation an abscess in the right ovary burst. The peritoneum was carefully washed out and the patient made an excellent recovery, and is now relieved of that almost constant pain and suffering which was exhausting her strength and making an invalid of an otherwise healthy woman.

Macroscopical examination: The ovaries and tubes are much enlarged; in the right ovary there is a large cavity, 1.5 ctm. in diameter, the contents of which escaped during removal. In the left ovary, at the distal extremity, there is a cystic protuberance, which, on section, is found to contain a grumous fluid, which being placed under the microscope shows pus-cells and débris.

Microscopical examination: Left ovary—The whole stroma is transformed into fibrous connective tissue, the bundles of which are freely interlacing. Some portions of the tissue are in a state of high waxy degeneration. The arteries in the middle coat are also in a state of waxy degeneration, the calibres of which are much narrowed, or nearly obliterated, owing to an outgrowth of the endothelia, which is the characteristic feature of chronic endo-arteritis. The tissue is crowded with amylaceous corpuscles. Diagnosis, chronic ovaritis; waxy degeneration of the newly formed connective tissue and of the arteries; corpora amylacea.

Right ovary contained a small abscess, with characteristic appearances.

Left Fallopian tube—The epithelium is preserved to a large extent, but is mostly destitute of cilia. The connective tissue is slightly augmented and of a delicate fibrous structure, in some portions with a waxy gloss, in other portions crowded with inflammatory corpuscles, also slightly waxy. Most of the arteries in their middle coats are enlarged and in a high degree of waxy degeneration. The calibre of some arteries is crowded with inflammatory corpuscles, a feature of endoarteritis. Both in the epithelial and connective-tissue layers numerous highly refractory structureless corpuscles are scattered—so-called corpora amylacea.

Right tube—The features clearly resemble those of the left; arteries dilated and tortuous; waxy degeneration; corpora amylacea.

Each of these patients had metrostaxis, and no appearance of menstruation since.

The microscopical examination of the appendages shows that each patient had *ovaritis* in some stage; some of them probably commenced menstrual life with ovarian congestion. The first case had hyperæmia of the ovaries when very young, which soon passed into acute ovaritis, then into a more chronic condition, then into cystic degeneration. The second case, an unmarried woman, suffered for years with acute and chronic ovaritis, long before the sarcoma was developed. The fifth case, also a young unmarried woman, had for years an inflammatory condition of the ovaries. The third case had evidence of acute and chronic ovaritis long before the complications of puerperal peritonitis. The fourth case, a young married woman of twenty-two, probably had ovaritis for nearly half of her life. The ovaries of Case VI. show in some portions chronic ovaritis, in others subacute, and in other portions a cirrhosed condition, which was the outcome of long-standing inflammation. In the seventh case the ovaries were cirrhotic and atrophied. The eighth and ninth cases, both single women, had ovaries organically diseased; in one there is not the least trace of normal ovarian tissue left, while in the other the whole stroma is transformed into fibrous connective tissue.

McBurney is often quoted as having said, "That it would be difficult to point out a single well-authenticated case of acute ovaritis out of the condition of pregnancy." The same idea seems to be repeated in most of our standard gynecological works. "The ovary is seldom the seat of inflammation except as the result of childbirth" (Emmet). "Acute inflammation of an unimpregnated ovary is of such rare occurrence that no case has come under my care" (West and Duncan). "Acute inflammation and abscess of the ovary is a condition rarely met with in practice" (Hewitt). "We have had but a single opportunity of studying non-puerpural acute ovaritis upon the cadaver" (Scanzoni). "Acute ovaritis is quite rare, except as a complication of peritonitis and cellulitis" (Thomas). The first-named author further says: "In attacks of peritonitis and cellulitis the ovary may have been only scorched in the general conflagration;" that "the ovary is scantily supplied with nerves, and the pain that is so frequently experienced in the neighborhood of the ovaries has no direct connection with the ovaries." So even our classical "ovarian irritation" is a delusion! Bennett says: "In nineteen cases out of twenty in which the ovarian region is the seat of a dull, aching pain, and apparently tender and swollen, there is no actual ovarian disease; the symptoms are almost invariably the result of some uterine lesion." Another English writer says: "In many cases the symptoms are purely neuralgic in character, independent of any local lesion;" that "pain is the patient's ailment," —"just like the back-ache which bears so large a part among the minor ills of women; and any treatment that directs the patient's attention to the seat of suffering is apt to perpetuate the evil instead of removing it." "Pain is the patient's ailment!"—thus this eminent author speaks of this formidable disease, which is so little understood. Yet it remains just as much a fact that there are unnumbered instances of both acute and chronic ovaritis, a countless number of women suffering years of martyrdom from disease of the organs, wearing out their lives, and the cause of suffering, never recognized, remains a secret which the grave finally covers, unless, perhaps, discovered at some post-mortem, and then not very much to the advantage of the patient. Scanzoni tells of a woman who died of pneumonia; at the autopsy it was discovered that "the ovaries were enlarged, effusion into the follicles, and in the parenchyma small abscesses of various sizes, all containing sanious pus." These conditions were not suspected before death. West and Duncan tell of a similar case. A woman died of bronchitis and emphysema; at the autopsy "the appendages were found matted together by firm adhesions, one ovary atrophied and the other enlarged by a cyst filled with grumous blood." The medical attendant imagined no trouble in this direction. The same author gives other similar cases. Hennig states that out of *eighty-one* post-mortems, a diseased condition of the ovaries was found in *fifty-three*, not only showing how frequent is the disease, but how infrequently it is recognized. Another author states that out of *sixty-six* post-mortems, in *twenty-one* the ovaries presented changes due to inflammatory action. In Dr. Wylie's clinic at the Polyclinic one-twelfth of the cases were diagnosed as having tubal and ovarian disease. Two years ago, Martin, of Berlin, reported that he found one in fifteen with diseased tubes. So other uterine clinics may show as many or more of these diseases if the diagnosis is as accurately made. Martin says, "The diagnosis receives too little attention;" probably not all are diagnosed.

But, whether recognized or not, there are still many cases of ovaritis, acute and chronic, from whatever cause they may be produced. If by septic poison, this septic poison may originate from other conditions of the system than the puerperium or from peritoneal inflammation. In a large majority of instances I believe *the ovary is infected by the unhealthy secretions from the uterine cavity*, which find their way through the Fallopian tubes to the ovary.[1] The ovary is more liable to, or in more danger of, this septic poison from the circumstance that, when an ovule escapes, there is left behind a funnel-shaped cavity, as if to invite or drink in the poison. The only wonder is that the ovary is not more frequently infected and diseased. The infection of the ovary from this cause is rendered yet more easy by any fusion or flexion of the uterus. In cases of flexion, especially, the uterine secretions to some extent almost necessarily find exit through the tubes, so infecting both tubes and ovaries.

The normal position of the uterus and its appendages is the most favorable for avoiding these possible dangers, which is also helped by the anatomical structure of the tubes, the longitudinal and circular fibres producing the peristaltic action which tends to force the secretions back into the uterus. Also the ciliated epithelii of the tubes aid in preventing fluids from passing into the peritoneal cavity; these millions of cilia may blow along the microscopical egg to its possible resting-place, also "hinder the contact of the spermatozoa with the ovum until the latter has reached the cavity suited for its maturation." Yet another *important function* of these ciliated epithelii is to *prevent fluids and noxious secretions from reaching the pelvic viscera*,[2] just as the cilia of the breathing organs hinder dust and dirt and other contaminations from reaching the lungs. I have watched the cilia in the living oyster, like millions of flashing diamonds, producing such currents in the water as bring necessary food to the inert mollusk. In the Fallopian tubes the cilia are no less effective, nor is their function less important. But young women, by a universal custom, push down, bind, or displace the uterus and its appendages, the *cilia can no longer do their duty*, the contagion finds an easy entrance, then commences a course of disease continuing and lingering for years.

I have a patient—a magnificently developed young woman—eighteen years of age. She should be the very picture of health, but her blanched lips, pale and agonized face, tell a different story. She says for years she has had such an *aching*, from which she is never free. When a little girl of fourteen she often leaned her head upon the desk and said, "What is it?" On examination I found the uterus completely retroverted, the fundus reached the lowest point in the pelvis, and was bound down by inflammatory adhesions; left broad ligament shortened and thickened; organs enlarged, extremely

[1] I [illegible] who died of [illegible] puriform pus, which was continued along the whole tract of the Fallopian tubes."

[2] It has lately been demonstrated that the epithelii in the uterus are ciliated, which further helps in this wonderful work.

tender, and dislocated low down into the retro-uterine cul-de-sac. Her vital organs were compressed and pushed out of position, and this displacement allowed the noxious secretions of the uterus to pass readily out through the tubes, and so infect the ovary, causing disease and enlargement, which last favored the dislocation. Another young lady called to see me, same age, and equally well developed—a pupil in one of our fashionable schools. She had a small, anteflexed uterus, and back of it the ovaries and tubes bound up in one mass of peritoneal inflammation, which inflammation was doubtless caused by the unhealthful and catarrhal secretions passing from the uterus through the tubes. A young lady, twenty years of age, called at my office. She had been treated for anteflexion. So extreme was her suffering during menstruation she had to keep her bed. But her trouble was *beyond* the flexion—probably *caused by it*.

There are many such cases, young women suffering from more or less disease of the appendages. They may put on their bright attire, their cheeks are flushed, they look well,' yet the cause of suffering is there. We see proofs of the frequency of these conditions in the number of married women who are incapable of bearing children. Marion Sims says, "Every eighth marriage is sterile." One woman whom I was called to see had been married ten years; no children. She had been much treated for dyspepsia, but for years had suffered pain and distress in the pelvis; a mass of disease was in the region of the appendages, and *there* was the trouble and there was the cause of her sterility, all resulting from infectious discharges. A young married woman called to see me; no children. Tubes swollen and adherent, derived from unhealthful uterine discharges. But in this case the discharges were *gonorrhœal;* more serious, more quickly infecting, and most disastrous of all! So young, so lovely, and her life so blighted! Sad that mothers, daughters, reared so tenderly, should be exposed to such a *vile danger*.

About the same time I was sent to see another patient. Found the appendages wrapped in a mass of inflammation, from septic poison from the puerperal state. Laying both hands upon the pelvis, she said, "Such a misery!" She had been suffering from it since the birth of her last child, eight years ago. Now she is confined to her bed most of the time, yet during these years she has been treated by various reputable physicians and surgeons for "womb disease." "When will we learn that all the ills of womanhood are not due to inflammation of the neck of the womb?" Many are treated for "womb disease," when the trouble is with the ovaries and tubes; probably the appendages are more frequently diseased than is the uterus. Meigs said, more than forty years ago, "Disease of the Fallopian tubes is many times unsuspected, when it is the cause of disease treated under another name."

But there are many other causes or conditions that are constantly operating to produce disease of the ovaries or of the uterine appendages; cold feet and extremities and imperfectly clad limbs tend to, and must necessarily produce, some form of congestion. Some of the most serious forms of pelvic congestion, or inflammation, result from a disturbance of the peripheral circulation. It should not be supposed that women are able to stand more exposure than the opposite sex, yet many of them go out with one thickness of muslin around their lower limbs, when the opposite sex will be found to have double and treble thicknesses of woollen goods. As one writer says, "Only fools and beggars take cold." No doubt this one cause, unbalancing the circulation, has produced many instances of disease of these important structures. There is a chill, symptoms of fever, and the trouble has commenced, more serious if during the period of menstruating. Scanzoni says, "We must seek the causes of ovaritis in some disorder of menstruation;" but *ovaritis will cause these "disorders."*

Another cause of frequent disease of these organs is nervous excitement during the developing period of life, exhausting the vitality when nature needs all the vital resources for maturing and growth. One of the saddest instances of this was a woman, twenty-five years of age, broken down with tubal and ovarian disease; her strength was used up—she had lived in a whirl of dissipation and mental excitement.

In the daily habits of young women there are many causes of ill-health, all having the tendency to react upon the condition of these vital organs. And when we think of the fine organization and exquisite structure of the ovaries, their important and complex functions, that they are performing the highest physical function[1]—perpetuating the race, elaborating that growth that by differentiation will develop into the most complex animal organization—and that while performing these important functions there is a certain amount of physiological hyperæmia, is it any wonder, especially when we consider the thousand untoward circumstances of woman's daily life, that these exquisitely delicate organs, while performing these complicated functions, repeated every month, should take on morbid conditions—that this physiological hyperæmia should be changed into unphysiological hyperæmia, congestion and inflammation? As they have a fine organization, they are apt to suffer more seriously.

During the function of ovulation young women should as much as possible rest in bed, just as for every one rest after a meal is promotive of good digestion, and the digestive process will go on more healthfully. And as there is no physiological function higher or more important than ovulation, so the more reason women should rest, especially when we consider the miserably inherited bodies which many of our American women possess, bodies that are poorly cared for, and have very little vitality. When we consider this, more especially is there need for rest during this period. But, let it be understood, there are many magnificently constituted women who can go forty or fifty years, severely taxed all the time, never resting during menstruation, yet never experiencing the least trouble, distress, or sensation in the performance of the ovarian function; just as there are a countless number of men, for as many years, amid their business activities, who never think of their stomachs or have any trouble therewith, while there are millions of others who have as many diseased peptic glands as there are diseased follicles in as many ovaries.

I have spoken of the *causes* of these diseases, and incidentally of their *prevention;* now a word as to their *cure*. How can these diseased conditions be relieved? Our standard English gynecological author, speaking of the pain in the region of the ovaries, says: "It is very hard to cure; leeches do not relieve, blisters sometimes afford ease, chloroform applied to the site generally gives temporary relief, so may camphor liniment, extract of belladonna," etc.; then adds: "I have never been able to trace the permanent cessation of suffering to the unaided use of any local means."

For the second patient mentioned, with anteflexion of the uterus and inflammatory masses on each side, probably much may be done: the adhesions may be softened, the peritoneal inflammation reduced, acute salpingitis relieved. But after all this is done there yet may be found an ovary that is more than "scorched in the general conflagration."

The patient who has enlarged and adherent tubes—shall we aspirate, run the risk of wounding vital structures and poisoning them with septic material, or shall we first open the abdomen to be sure it is hydro-salpinx, and if it is, then aspirate?

The enlarged tubes of the patient with gonorrhœal in-

[1] "All the facts of comparative anatomy indicate that the female organism is in advance of the male" "Within the ovary there is ceaseless activity, changes as subtle and eluding as the vital principle itself" (Coe).

fection are without doubt filled with pus, even the fimbriated extremities are possibly distended into pus-sacs and closely agglutinated to a diseased ovary, the cilia desquamated, and the lining membrane changed. Can such organs be restored to health, or to their normal function?

How shall we help the last-named case with enlarged tubes and ovaries diseased from septic material of the puerperal state? She has grown gradually worse under the varied treatment of many physicians.

In the young woman with dislocated ovaries, the first patient mentioned, treatment has removed lymph-like adhesions which bound down the uterus; but how are the ovaries to be held in position? By broad-brimmed pessaries? Who has succeeded? Where are the pessaries that will hold them in position? The patient is on the eve of a brilliant marriage. Shall we leave the ovaries to "give her the chance of some future baby"[1]—leave the woman with the certainty of future trouble, the possibility of being permanently invalided? Even if the ovaries are healthy, the tubes may be so changed in structure, or so misplaced by adhesions or some shortening, that they "cannot acquire their periodic relations to the ovary," any one of which conditions will be a cause of sterility. Shall we resort to Imlach's suspensory operation, oöphorraphy,[2] by which the ovary is stitched up to the infundibulo-pelvic ligament? An ovary so displaced and so sensitive is doubtless very much diseased, and from the history of the case we would judge the ovaries had been long and profoundly diseased, and consequently must have undergone certain organic changes, and where would be the good of stitching them up? Lawson Tait, who is the best authority on this subject said: "When there is really chronic inflammatory disease of the ovary, no such operation can be expected to be successful." Soon after the report of Imlach's operation appeared in the *British Gynecological Journal*, Dr. Paul Mundé, of New York, sent me the following note in reply to a letter of inquiry I had sent him: "I should feel doubtful whether in reality such an accurate anatomical adaptation could be secured as to facilitate or permit conception as Imlach intends. It seems a considerable danger to incur, merely to retain in *approximately* normal position a prolapsed and perhaps an already diseased ovary."

If we leave the ovaries as they are, it is leaving the patient with a source of misery and suffering, probably in time may compromise her life; or, if she marries, she will not only be sterile, but unable to submit to the marital relations.

Were she a dispensary patient, a young girl who by labor had to earn her own bread, and for whom it did not count much whether she had children or no, to save all future trouble and suffering, to enable her to be a useful member of society, to enable her to do her daily work, and to prolong her life I would at once advise the removal of the uterine appendages. And, after all, what better can be done for this patient? Bantock said (November 11, 1885) "he knew of no remedies which had the slightest effect upon a diseased ovary." Lawson Tait said, the same date, "his own experience was that an ovary once inflamed and adherent, the disease was practically incurable save by removal (*British Gynecological Journal*, p. 383).

But lately there is a great hue and cry about the possible future baby. They do not stop to think of the countless number of women who are barren and childless for years from various forms of uterine disease—"a drop may stop a dynasty." When women are suffering from hopelessly diseased tubes and ovaries they must not be "unsexed," they must continue years in torment and misery and inability for any kind of employment or avocation, because perhaps in the diseased ovary there may be a healthy follicle, which may contain a healthy ovum, which may find its way through a possibly diseased tube, and *possibly* find other favorable conditions—like Mrs. Toodles who purchased a door-plate on which was cut the name of Thompson, because she might have a daughter, she might grow up, and might marry a man by that name. Removing diseased uterine appendages is not unsexing a woman, it is restoring her from helpless invalidism to all the possibilities and opportunities of life and labor. It is not taking away the possibility of her having children—that has already been done by disease—it is only removing a cause of suffering. In 1882 a young woman, twenty-seven years of age, was brought to me from Maine, married at fifteen, and again at twenty-two; no children. Uterus retroverted, bound down by firm adhesions, and the appendages wrapped up in a hopeless mass of disease. Thus she had been suffering for years. Hystero-epilepsy and other grave nerve-symptoms were developed. To relieve the constant pelvic pain, and possibly also to relieve some of the nerve-symptoms, I advised the removal of the uterine appendages, but was met by the objection, not only that a former medical attendant had advised a long course of treatment by bromides, etc., to cure her "nervous diseases," but mainly the objection to removing the uterine appendages was that she would be rendered sterile, that we would "take away her capabilities of having children!"

A few months, after I removed the uterine appendages, and below we have a representation of them. We see how completely all functional action must have been destroyed.

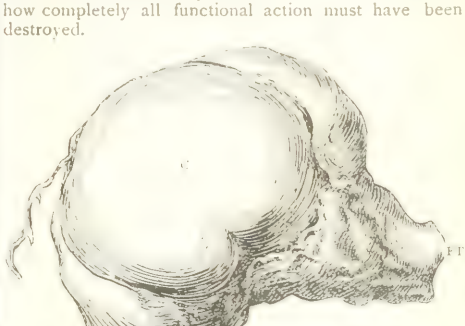

FIG. 3.—Ovary, posterior surface; FT, tube flattened out, closely adhering to cyst. Tube-walls extremely [illegible].

The right ovary is enlarged, containing a cyst. The fimbriæ have disappeared from the adherent tube, and its extremity is closely glued to the ovary. Only small remnants of ovarian stroma left, and under the microscope the remnants are found to be in a *thoroughly atrophic* condition, cirrhotic atrophy, mainly consisting of dense fibrous connective tissue, in which are many small amylaceous corpuscles. The free arteries that were left were in a state of waxy degeneration. Thus *all normal structure* was *utterly* destroyed, and any physiological function would have been entirely impossible.[1]

Winckel is quoted in a late number of the *Philadelphia Medical News* as saying: "The time is not far distant when the extirpation of the healthy ovaries for the cure of dysmenorrhœa, ovaralgia, epilepsy, hysteria, etc., will stop." But, Mr. Winckel and Mr. Rip Van Winkle, women with these conditions do not, as far as observation goes,

[1] Routh: British Gynecological Journal.

[2] The stitching up of the ovary was suggested to my mind when, three years ago, I read Tait's method of stitching up the uterus, and doubtless his [illegible] the whole field.

[1] This case was reported in the American [illegible] microscopical examination was [illegible] conclusions: "1. The operation should have been performed on the patient years before. 2. There was no other way to relieve her than by the operation. Soon after the publication of the article I received a letter from Lawson Tait, Birmingham, Eng., in which occurs the following sentence: "I agree with your conclusions concerning the case absolutely. The whole gist of modern abdominal surgery lies in an earnest and continuous plea for early interference. There can be no doubt that the only fear about such cases is that they are allowed to go on so long without operation."

have "healthy ovaries." I have never seen the ovaries removed in a single instance but they were more diseased than the symptoms had led me to suppose. Dysmenorrhœa may come from other causes, *but often* it results from a hopelessly diseased condition of the appendages. Incurable epilepsy may and has been helped by these surgical procedures. Hysteria may demand it, and ovaralgia is only an unmeaning word to sum up the suffering that may come from diseased ovaries and tubes; and these sufferings and this irritation may be so great as to render abnormal the mental conditions.[1]

There is no advance made in modern surgery that will do more good, save more lives, or relieve more suffering, or add more to the sum of human life or human happiness than this one operation, known as "Tait's operation." It will save more lives than ovariotomy, because more need it.

In 1847 the eminent and distinguished Charles D. Meigs, Professor of Midwifery and Diseases of Women in the Jefferson Medical College at Philadelphia, reported a death from Fallopian pregnancy. Twenty hours after death, when inspecting the abdominal cavity, he said, "What, alas, can we do in these cases? We could make an incision and clean away the coagula and the serum. But who is he bold enough to do so? Who is he astute enough to discriminate with so much clearness as to warrant him in the performance of gastrotomy for Fallopian pregnancy? There is no such wise and bold surgeon."

But there is, and this wise surgeon has led us out of this wilderness of doubt to the clear light of what is best to be done, and showed us how to do it successfully.

Clinical Department.

TREATMENT OF WHOOPING-COUGH.

Dr. E. W. Hedges, of Plainfield, N. J., writes: "In an editorial of July 31st you speak of various recent methods for the treatment of whooping-cough. One of these plans I have tried quite largely in my own practice, and with such gratifying results that I venture to send you a short account of it.

"The remedy used was resorcine in a two per cent. solution, as recommended by Dr. Moncorvo, of Brazil, and the method of applying it was by a hand-atomizer (Perkins), inhaling the spray for four or five minutes every three hours. In the case of adults, where the treatment was faithfully carried out, the results were uniformly successful, a cure being effected inside of nine days in every instance. With young children (two years and under) it was found impossible to use the spray, and even with older ones, where the treatment was intrusted to mothers or nurses, the cough was often modified rather than checked; but in every case, young or old, where the spray was properly applied a cure resulted.

"A few cases will illustrate the plan:

"Miss S——, aged nineteen, had coughed for six weeks, expectorated large quantities of mucus, and was waked up four or five times each night with paroxysms of coughing. After the first day's use of resorcine spray she slept through the night without waking, something she had not done before in weeks. The next day her cough was decidedly lessened, and after the third day it disappeared altogether. She continued the spray for a week longer, and had no return of the cough. In this case, as in all the others, no internal medication whatever was given.

"Mrs. A—— had been coughing three weeks. After one week's use of resorcine as above, the cough was completely checked and did not return.

"Miss O——, five years of age, began treatment as soon as it was certain she had whooping-cough—*i. e.*, in about two weeks after the cough began. Two applications daily for a week so far checked the cough that the mother did not think it necessary to bring her any longer to the office. A slight cough remained, however, which, upon the discontinuance of the spray, quickly grew worse and soon returned with its former violence.

"Another case illustrates this same tendency for a return of the cough unless it is first completely stopped.

"Mrs. M—— had coughed for over five weeks severely, with vomiting, profuse expectoration, and violent paroxysms. She noticed a marked improvement immediately after beginning treatment, and in four days was so nearly well that she thought it useless to do anything more. She stopped the spray, and the cough quickly returned, and on the seventh day, when she came to my office, the cough was nearly as bad as ever. The spray was ordered again to be persisted in, and I am expecting a report from her in a few days.

"Do not these cases render plausible the hypothesis that micrococci, by their presence along the upper air-tract, are the cause of whooping-cough, and that unless these are thoroughly destroyed by germicides those that remain rapidly multiply and bring on a train of symptoms as before?

"Certainly the treatment is a pleasant one, easily carried out when the patient is not too young, is inexpensive, and most efficient."

THE OPHTHALMOSCOPE IN THE HANDS OF THE GENERAL PRACTITIONER.

Neil J. Hepburn, M.D., Instructor in Ophthalmoscopy at the New York Polyclinic, sends us the following communication: "A few remarks on the use of the ophthalmoscope by the physician in general practice may not be out of place here. But before proceeding to that branch of our subject it may be as well to call attention to a still simpler mode of examining the transparent parts of the eye, known as 'oblique illumination.' To apply this method, the patient is seated in a darkened room with a light to the temporal side and somewhat forward of the plane of the eye to be examined. A convex lens of two or three inches focus is then held at its focal distance from the observed eye in such a position as to intercept and concentrate the rays of light falling upon the cornea. The observer is to be on the nasal side of the observed eye, in a position to receive the rays reflected from the illuminated surface. By causing the patient to look up and down, to the right and left, the whole cornea may be inspected. The normal cornea, when examined in this way, shows a faint silvery haze. If it appear as clear as under ordinary illumination, as occurs in rare instances, it is said to be an indication of strumous taint. If there are opacities they will appear more opaque and of a more pronounced whitish or yellowish tinge. By bringing the light by degrees more and more directly in front, and the concentrating lens a little closer to the observed eye, the iris, lens, and anterior portion of the vitreous may be explored. A second convex lens may be used between the eye and the observer to magnify the image.

"After completing the inspection by the above method, if we wish to see further into the interior of the eye we have recourse to the ophthalmoscope. There are two methods generally employed in using the instrument: the direct, which gives a greatly magnified picture of a small part of the fundus oculi, and the indirect, with larger field and a low magnifying power. Hence the 'indirect method,' though somewhat more difficult for the beginner, is better adapted for a general survey, while the 'direct' is more useful for the study of details.

"In the indirect method we employ the same lens used in oblique illumination, the light being reflected into the eye from the mirror of the ophthalmoscope. The source

[1] [illegible] reports [illegible] "[illegible] both mental and physical" (Medical News, December 27, 1884).

of illumination should be on the temporal side, and behind the plane, of the eye to be examined, the observer sitting in front and a little to the same side, at a distance of sixteen to twenty inches. The observer uses his right eye if the patient's right eye is under observation, and his left eye if the left eye is to be looked at. Now the patient is directed to look directly forward to bring the optic-nerve entrance into line, and the light thrown directly into the pupil. Then interpose the convex lens, held in the other hand, directly in front of the observed eye, and at a distance from it of one or two inches. The optic disk and a considerable portion of the fundus can then be seen. If the view be not clear, it may be necessary to turn on a plus or minus glass behind the mirror till the greatest distinctness possible is obtained, or to move the convex lens to one side or the other to bring the disk into view. By having the patient look up and down, to the right and left, the greater part of the fundus can be examined, and the position of opacities in the media determined by their parallax. By keeping the disk in view, and moving the condensing lens directly away from the eye toward the observer, a very good idea of the optical condition of the eye may be obtained. If the disk increase in apparent size as the lens recedes from it, the eye is myopic. If the image diminish on recession of the lens, there is hypermetropia. Increase in only one diameter denotes simple myopic astigmatism, as diminution in only one diameter signifies simple hypermetropic astigmatism. If the image of the disk increase or diminish all round, but more in one direction, there is compound astigmatism. If one diameter increases while the cross diameter diminishes, there is mixed astigmatism. If the disk take on grotesque changes in shape, and the vessels appear irregularly broken, you have irregular astigmatism. If there is no change in size or shape, the eye is emmetropic. The more rapid the change, the higher is the degree of error. The condensing lens must at no time be moved farther than its focal distance from the eye under inspection.

"In the direct method, the positions are relatively the same except that the condensing lens is dispensed with and the observer approaches his eye as near the observed eye as he can while keeping it illuminated. The beginner should look through any lens in the ophthalmoscopic disk which will give him a clear view of the fundus oculi, without regard to the refraction. When he has become more apt at getting a good view, he may, after correcting any error of refraction which may exist in his own eye, find the *weakest minus* or the *strongest plus* glass, with which he gets the clearest picture. The edge of the optic disk or the small retinal vessels near the macula are good points to look at for this purpose. Steady practice of this sort will enable the observer in time to relax his accommodation entirely, so that he can accurately determine the refraction in the observed eye in every case.

"It is essential in beginning the study of ophthalmoscopy, that the patient's pupil be dilated as widely as possible by a mydriatic, and in examining by the 'direct' method, the effect of atropine is much to be preferred, as it not only dilates the pupil but suspends the accommodation."

VERY SIMPLE.—A classification of insanity is given by Dr. John P. Gray, which for simplicity quite equals the famous classification of skin diseases into "eczema and not eczema." It is as follows: *Mania*, manifested by delusions of excitement, expansive ideas, exaggerations, self-consequence, incoherence, etc. *Melancholia*, manifested by delusions of depressing character, painful ideas, and apprehensions. *Dementia*, representing conditions of mental failure and feebleness of mental action. All cases of insanity come under these three heads. Cases may be acute, subacute, chronic, periodic, paroxysmal, but they are either mania, melancholia, or dementia.

AMBULANCES alter cases.

Progress of Medical Science.

REMOVAL OF CALLUS BY THE GALVANIC CURRENT.—Dr. Meyer, of Berlin, records the following case (*Deutsche Med. Wochenschrift*): A boy, thirteen years old, had sustained a fracture of the upper arm. After a plaster-of-Paris bandage had been applied, the arm was in three weeks so far healed that the lower and upper arms stood at an angle of 80°, the wrist being tightly drawn up, and the fingers lying without power of motion on the hand. Attempts had been made in vain to produce extension. When he was brought to Dr. Meyer, the latter discovered on the inner side of the elbow-joint a callus that occupied a third of the lower arm and had included the flexors of the fingers, thus depriving them of active and passive motion. On the application of the induction-current to the upper arm there was considerable movement in the muscles supplied by the radial nerve. When the ulnar nerve was brought under the influence of the current a slight movement of the abductor pollicis was observable, while irritation of the median produced a tingling sensation down into the hand. The galvanic treatment was as follows: The arm was laid on a conductor of the size of an octavo sheet, and a small electrode was applied, partly to the median nerve and partly to the callus. Frequent voltaic alternatives were employed. After sixty applications the boy could stretch out his arm fairly straight, and the place of the fracture could now be plainly felt on the inner side of the upper arm. After ninety applications the callus was reduced one-third, the active movement of the elbow-joint was nearly restored, and that of the wrist considerably improved. After one hundred and eighteen applications the muscles generally were in so good a condition that there could be no reasonable doubt about the perfect restoration of the use of the hand. This, Dr. Meyer thinks, shows that of all means the galvanic current is the most intensely sorbefacient.

NITRATE OF POTASSA AND MERCURIAL INUNCTIONS IN ACUTE RHEUMATISM.—In *The Russian Medicina*, Dr. Grinevitzky advocates the treatment of acute articular rheumatism by the internal use of nitrate of potash (two drachms daily, in solution with raspberry syrup), and by the inunction of a mercurial ointment. The author's formula is: ℞. Ol. hyoscyami, ʒj.; ung. hydrarg. cinerei, ʒij.; ext. aconiti, ʒj. M. To rub in the joints affected every morning and evening. Fever gradually abates; the pulse becomes less frequent; articular pain, swelling, and heat decrease. The patient recovers in one or two weeks, according to the severity of the disease and its duration before coming under treatment. When resorted to in the very beginning of the affection, the treatment prevents spreading of the latter to other joints, or, at any rate, mitigates any subsequent symptoms. The author's assertions are based on an experience of more than twenty years' duration. None of other old or new anti-rheumatic remedies can compete with nitrate of potassa, as the author says. Frictions alone only somewhat mitigate the symptoms, but do not cure the disease, while the salt alone acts well, though recovery then becomes more protracted than where the inunctions are employed simultaneously. In conclusion, Dr. Grinevitzky states that, for the sake of comparison, he tried to treat some cases of rheumatism by nitrate, carbonate, and subcarbonate of soda, and by carbonate and subcarbonate of potassa, but did not obtain from them any use whatever.

GONORRHŒAL RHEUMATISM.—Loeb is of opinion that gonorrhœa is only complicated by rheumatism in those cases in which the gonorrhœal process has attacked the hinder portions of the urethra; and in favor of this view he adduces the two facts, first, that the rheumatic symptoms never occur in the early stages of a gonorrhœa,

and, secondly, that in the great majority of cases the rheumatism is never seen at all during the first attack, but only after subsequent attacks, when the posterior parts of the urethra are almost certain to be involved. As to the disputed point, whether the rheumatism is to be considered as a disease *sui generis* or as merely an ordinary rheumatic inflammation of the joints predisposed by the gonorrhœal infection, he comes to the conclusion that *polyarthritis rheumatica* and gonorrhœal rheumatism are two perfectly distinct diseases, and he bases his conclusions on the following grounds: 1st. The difference in the relation of the fever to the local changes in the two diseases—in ordinary rheumatism the fever and the joint-affection generally running hand in hand, whereas in gonorrhœal rheumatism the fever is always slight and in most cases is almost, if not entirely, absent. 2d. The difference in duration of the two processes, the gonorrhœal rheumatism running a much longer course. 3d. Gonorrhœal rheumatism is much less erratic in its character than ordinary rheumatism. 4th. The frequent association of gonorrhœal rheumatism with inflammation in the eyes—this inflammation, according to him, occurring sometimes without contagion, and being simply another local expression of the gonorrhœal infection. 5th. The less frequent implication of the heart in gonorrhœal rheumatism. 6th. The greater tendency to inflammation of the sheaths of tendons and synovial sacs generally in gonorrhœal rheumatism. 7th, and lastly. The difference in behavior of the two processes toward the salicylates. Loeb thus considers gonorrhœal rheumatism as an infectious process, the seat of infection being the hinder parts of the urethra; and this view receives apparent support from the recent discovery of a specific organism in the gonorrhœal secretion, the gonococcus. Some doubt, however, still exists as to the specific character of this organism; and hence Loeb is more inclined to think that the cause of the infection will be found in non-specific organisms, examples of whose action in producing inflammation in joints we have, according to him, in the rheumatic affections of the joints which sometimes occur during the puerperium, also along with bronchiectasis, scarlet fever, and dysentery. As to the treatment, it is especially important as quickly as possible to cure the inflammation in the urethra, and especially of the hinder parts.—*Practitioner.*

Decortication of the Finger.—Under this title M. Thomas, of Tours, described a peculiar accident, the effects of which he was called upon to repair. A man who wore a plain ring on his finger was suspended by it from a railing, and the ring slipped off, carrying with it the entire skin of the finger from its root to the tip. The cutaneous envelope was immediately replaced under antiseptic precautions. The union was not complete, but all the integument covering the first phalanx and a part of the second was preserved.—*Journal de Médecine et de Chirurgie Pratiques*, June, 1886.

A Simple Method of Removing Wens.—In the *Northwestern Lancet*, July 15, 1886, Dr. Lauenstein's simple method of removing sebaceous cysts of the scalp is described. The skin over large wens of the scalp is often so thin that, in the commonly practised method of extirpation with a free incision over the convexity of the tumor, the sac is often ruptured in spite of all care, and through collapse of the walls of the sac the separation of the skin is rendered difficult and protracted in a disagreeable manner. This accident, unless it is a case of inflamed wen, may be avoided with certainty by a simple expedient, which has recommended itself to him on account of the rapidity of its execution, and which will be readily appreciated by those to whom it often happens to be pressed for time, or who, living in the country, are obliged to operate without skilled assistants. After shaving and cleaning the neighborhood of the wen, he makes a radial cut, about one inch long, through the skin where it is separated from the capsule of the wen, for instance, on the back of the head at the lowest point of the base of the tumor; through this slit he introduces the slender handle of the scalpel used, or a similar instrument, between the skin and sac, more or less deeply according to the size of the tumor. This is very easily accomplished, and he then makes several sweeping movements of the scalpel-handle to the right and left, thereby separating with ease the sac from the skin. The elasticity of the skin allows almost the whole circumference of the wen to be separated in this way in a few seconds. He then cuts, with one snip of the scissors, the skin over the crown of the tumor as far back as is necessary, and shells it out whole from its seat. There is often no bleeding, because of the division of the vessels of the sac by a blunt instrument. The rest of the treatment—sutures, drainage—is not affected by this procedure; nevertheless, he adds that any crushing or tearing of the edges of the wound is completely avoided.

A Rare Case of Aphasia.—Dr. Volland reports the following peculiar case: A strong, healthy boy, fifteen years of age, fell into the cellar of a house which was in the course of construction, receiving a wound over the right parietal bone. The periosteum was stripped from the bone for a considerable distance; but the bone was not broken, and there were no symptoms of fracture of the skull. After a period of unconsciousness lasting three days, the patient came to himself. There was no paralysis; but, while apparently understanding everything that was said, he was unable to speak. The only word which he used in all questions and answers was a stammering "anna," and the same word was the only thing legible that he could write; but it was found that he could count correctly and clearly, and could also add, subtract, multiply, and perform any numerical problems with ease. After about two weeks the patient began to learn a few words. He would first decipher a word here and there in reading, and soon was able to repeat the word after reading it. The wound, which was received in March, healed rapidly, and the following winter the boy went to school. Here he was able, only with the greatest difficulty, to speak or write a connected sentence, and was very backward in reading and writing, but in mathematics easily kept up with the brightest and most advanced of his schoolmates. Six years later there was still much difficulty in speaking, and he often forgot words when at all excited. Within the last year he has had occasional attacks of vertigo, so that he would have to take hold of some support to keep from falling. The general nutrition and bodily strength are excellent.—*Centralblatt für Klinische Medicin*, July 10, 1886.

The Diuretic Action of Watermelon.—Dr. Popoff has been experimenting with the inspissated fresh juice, or syrup, of this fruit, and has found that it possesses marked diuretic properties (*London Medical Record*, June 15, 1886). When animals received from fifty to one hundred grammes of the syrup (with food) in twenty-four hours, the daily quantity of urine was three or four times greater than under ordinary conditions; again, on intravenous injection of the syrup, the urine for several minutes flowed in a stream from a cannula tied into the ureter. In dogs, the internal administration of five hundred grammes at a time produces no effect, except powerful diuresis. Intravenous injection of one to two grammes of the syrup causes an immediate increase in the secretion of urine, the latter assuming a dark color, and containing sugar. This increase lasts for ten to sixty minutes, and is accompanied only by a slight fleeting decrease of the blood-pressure. On the injection of 0.25 to 0.5 gramme for each kilogramme, a considerable fall of the pressure and a great acceleration of the pulse rapidly follow. An intravenous injection of 3.0 grammes per kilogramme produces a further fall of the pressure and a fleeting increase, with a subsequent sudden enormous decrease in the frequency of the pulse, the animal dying from cardiac paralysis. As some special

experiments show, the quickening of the cardiac action is dependent upon the syrup acting on the peripheral ends of the vagi. In all cases, intravenous introduction of the syrup rapidly produced a strong sedative effect, "the animal remaining strikingly quiet, and giving no response to tactile or even pathic irritation." Another group of experiments showed that the diuretic action of melon-syrup was dependent mainly upon its direct influence on the renal tissue.

Treatment of Neurasthenia and Hysteria.—In a recent paper Dr. Burkart reports a number of cases of hysteria and neurasthenia, treated by Weir Mitchell's method of rest in bed, massage and faradization of the muscles, overfeeding, and isolation, and points out the circumstances under which this method may be expected to give good results. The first condition of success is that the patient shall have preserved a certain amount of will-power, and shall have a clear idea of what it is intended to accomplish by a strict carrying out of the method. As contra-indications he mentions an irritable condition of the brain as regards its psychical functions, marked hyperæsthesia of the abdominal sympathetic, and uncontrollable reflex vomiting. If, however, this form of vomiting be absent, the presence of dyspeptic symptoms indicates a proper subject for this method of treatment. The digestive powers are very quickly restored in hysterical patients, though neurasthenia gastrica requires more time for its correction. Cases of spinal irritation are also speedily relieved by Weir Mitchell's plan.—*St. Petersburger Medicinische Wochenschrift*, June 28, 1886.

The Etiology of Puerperal Cystitis.—In several cases of puerperal cystitis, Dr. Bumm reports that he found a diplococcus resembling closely the gonococcus, but distinguishable from it by staining and cultures. The cocci were disposed in little collections, often lying within or around a cell. This micro-organism is said by Doléris to be constant in the lochia, and it is supposed that it gains entrance into the bladder during catheterization. In experiments upon animals Bumm found that the injection of these microbes into the bladder was seldom followed by any inflammation unless the mucous membrane were injured. In the latter case a catarrh, with profuse purulent secretion, was excited. The marked suppuration attending puerperal cystitis was therefore supposed to be due to these diplococci from the lochial discharge. When no wound of the mucous membrane of the bladder was present, the micro organisms found no lodgment, and were washed away by the urine.—*Allgemeine Medicinische Central-Zeitung*, July 17, 1886.

Another Method of Artificial Respiration.—Mr. J. A. Francis describes the following method of artificial respiration in the *British Medical Journal*. The body of the patient is laid on the back, with clothes loosened, and the mouth and nose wiped; two bystanders pass their right hands under the body at the level of the waist, and grasp each other's hands, then raise the body until the tips of the fingers and the toes of the subject alone touch the ground; count fifteen rapidly; then lower the body flat to the ground, and press the elbows to the side hard; count fifteen again; then raise the body again for the same length of time; and so on, alternately raising and lowering. The head, arms, and legs are to be allowed to dangle down quite freely when the body is raised. The author alleges that this method is most successful, and it is so simple that anyone can perform it without any teaching.—*London Medical Record*, June 15, 1886.

Syphilis Aborted by Sulphur Baths and Mercurial Inunctions.—Dr. P. J. Kalashnikoff records the case of a soldier who was admitted with a characteristic induration on the penis at the site of a recently healed primary ulcer, and with a marked universal adenitis. After ten sulphur baths, the sclerosis became exulcerated. The ulcer did not yield to local medication. Under the influence of the inunction of gray mercurial ointment (ten frictions of one scruple each, and ten of half a drachm), and sulphur baths (fifty one), the ulcer rapidly healed, and sclerosis and adenitis disappeared. His skin and mucous membranes remained healthy. Not a single syphilitic symptom made its appearance subsequently (more than six months passed from his cure up to the date).—*London Medical Record*, June 15, 1886.

Radical Cure of Hydrocele by Carbolic Acid.—Dr. G. Buckston Browne reports in the *British Medical Journal* of June 26, 1886, a case of hydrocele cured by injection of carbolic acid after iodine had failed. He writes that a gentleman, twenty-three years of age, consulted him in the early part of April about a hydrocele, which had followed an attack of orchitis fourteen months before. He was going abroad, and urgently desired a radical cure. On April 13th, Dr. Browne tapped the hydrocele and drew off six ounces, and injected two drachms of tincture of iodine. Next day there was pain in the groin and loin, and the scrotum was tender and full. In four days so much fluid had re-collected in the tunica vaginalis that he tapped again, and drew off two ounces. In three days the same amount of fluid had again collected, and he then determined to give carbolic acid a trial, being encouraged to do so by the paper of Dr. Keyes in The Medical Record of February 20, 1886. On April 20th he tapped, and drew off two ounces, and then injected, with an ordinary hydrocele-syringe, sixty minims of pure carbolic acid, dilequesce l with five per cent. of glycerine. The patient was ignorant of what had been injected, but at once said he tasted carbolic acid. Next day the part was swollen, but not very tender. No fluid was ever again detected in the tunica vaginalis; and he left London in a week, and has remained well ever since. The cure was rapid, complete, and nearly painless.

Lactic Acid as a Caustic.—It will be remembered that Mosetig has recommended lactic acid as especially valuable for use as a caustic from the fact that it spared the healthy tissues. This claim would seem, however, to be disproven by Drs. Spitzer and Hermannn in some recent experiments. These observers publish eight cases of lupus and epithelioma treated with concentrated lactic acid as proposed by Mosetig, and state their conclusion as follows: 1, The pain produced by the cauterization with lactic acid is at least as great as that caused by any other caustic; 2, the patients prefer invariably any caustic to lactic acid; 3, the action of lactic acid resembles that of other caustics, but is less energetic; 4, healthy tissues are not spared any more by this than by any other caustic; 5, lactic acid has to be employed for a much longer time than chloride of zinc and other energetic caustics.

Chlorotic Fever.—Mollière was the first to call attention to the fact that a mild febrile condition is frequently present in chlorosis, and one of his pupils, Leclerc, has extended his observations and confirmed the statements of his teacher. In thirty cases of true chlorosis, in which the temperature was taken with the greatest care, the author noted oscillations ranging from 99.7° to 101.5° F. The fever assumed one of two forms, either a continued febricula without noticeable oscillations, or a febricula with exacerbations. But in the cases observed the slightest accident might occasion a very decided rise of temperature, the susceptibility of chlorotics resembling in this respect that of children. The duration of the fever varied within wide limits, and in general corresponded to the slowness with which the chlorosis disappeared. The frequency of chlorotic fever is a matter not yet determined, but the elevated temperature is not an invariable accompaniment of the chlorosis. No satisfactory explanation of this occurrence has yet been given, and the experimental researches of the author have as yet been without result.—*Rivista Clinica e Terapeutica*, June, 1886.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, August 21, 1886.

RECENT CONTRIBUTIONS TO THE SUBJECT OF ANEURISMS OF THE HEART AND AORTA.

THE records show that about one death in every eight hundred, in this city, is due to aneurism. The very great majority of these deaths occur from aneurisms of the aorta. Although Crisp's statistics make popliteal aneurism second in frequency to that of the thoracic aorta, yet modern surgery has made death from this source comparatively infrequent. As not a few persons die with small or unrecognized aneurisms, it is safe to say that aneurismal disease is of tolerably frequent occurrence.

Of the numerous reports and papers upon aneurism that have been contributed of late, a majority are purely clinical. We leave it to our readers to judge of the interest and importance of such kind of work. The symptomatology of aneurism has been very thoroughly worked up, yet it is very true that the field is not entirely closed.

In the line of clinical study, Dr. Hobart A. Hare (MEDICAL RECORD, May 15, 1886) has reported a case of thoracic aneurism occurring in a girl only seventeen years old, and although the tumor bulged well up into the suprasternal notch, there was no dysphagia, dyspnœa, loss of voice, or dropsy. There was double aortic disease and enormous cardiac hypertrophy. In another case the patient was only twenty-eight. Here there was aneurism of the arch, with pressure on the trachea. The interesting point was that the pain, and even delirium, from which the patient suffered was relieved by hyoscyamine and increased by morphine.

A very rare case of aneurism of the hepatic artery (the eleventh on record) was shown to the London Clinical Society recently by Dr. R. Caton. The diagnosis was not made before death.

Equally rare are cases of aneurism of the splenic artery, of which Dr. F. Ch. Turner has shown a specimen ("Trans. of Lond. Path. Soc.," vol. 56). The disease occurred in a laboring-man, aged thirty-seven, who died suddenly from rupture of the sac.

Mr. Percy Kidd has shown to the London Pathological Society four specimens illustrating chronic cardiac aneurisms. In all cases the sac involved more or less of the interventricular septum, and, as is usually the case, was connected with the left ventricle. The cause of such aneurism is generally believed to be a chronic myocarditis, but these cases showed that one factor was the abnormal friction of endocardial surfaces upon each other.

Cardiac aneurisms are most frequently found at the apex of the left ventricle, and Dr. S. J. Sharkey has shown a specimen illustrating this ("Trans. of Path. Soc. of Lond.," vol. 56).

Acute aneurisms of the aortic and other valves are not infrequently caused by ulcerative endocarditis. Mr. Norman Moore reports a case illustrating this ("Trans. of Path. Soc. of Lond.," vol. 36).

An interesting illustration of a rare clinical variety of aneurism was exhibited by Dr. F. Ch. Turner to the London Pathological Society. The patient, a syphilitic man, died with symptoms of thoracic aneurism, a most notable feature being an œdema and lividity of the face and upper extremities. On post-mortem examination an aneurism of the ascending aorta, three inches and a half long, was found, communicating freely with the superior vena cava. Dr. Turner reported another curious case in which a thoracic aneurism had ulcerated through and finally burst into the œsophagus. At the autopsy the stomach was found full of blood. In still another case there was a dissecting aneurism of the arch of the aorta, which had perforated the pericardium. The patient died suddenly and it was found that the blood was diffused throughout the mediastinum and had also filled the pericardial sac.

Dr. F. de Haviland Hall (*Brit. Med. Journal*, December 19, 1885) reports a case of aneurism of the ascending and transverse portion of the arch of the aorta which is interesting, because no symptoms of aneurism were noted except those of pressure on the trachea and recurrent nerve. A malignant tumor was, therefore, diagnosticated. The symptoms were dyspnœa, cough, purulent expectoration, and paresis of the posterior crico-arytenoid muscles. On post-mortem examination an aneurism of the size of an orange was found, involving the posterior wall of the ascending arch and pressing on the left vagus and left recurrent.

Mr. T. G. Styan (*St. Bartholomew's Hosp. Reports*, xxi.) reports three cases of aortic aneurism, all of which had this peculiarity, that they ruptured into the left pleural cavity. In one of the cases the symptoms were those of biliary or intestinal colic and the presence of an aneurism was not made out during life.

Mr. Henry Morris ("Medico-Chirurg. Trans.," vol. lxviii.) reports a case of aneurism of the abdominal aorta, which caused gangrene of the right lower extremity, partly by embolism and partly by pressure on the inferior vena cava. The thigh was operated upon on account of the gangrene, but the patient died eight days later.

Dr. George B. Shattuck (*Boston Medical and Surgical Journal*, April 9, 1886) describes the case of a man, fifty-one years of age, who was brought to the hospital suffering from a pulsating tumor in the left lumbar region. He experienced intense pains; the tumor increased in size until it was as large as a water-melon. Death occurred, and at the autopsy an enormous false aneurism was found in the left flank, communicating with a true aneurism of the abdominal aorta.

In the line of diagnosis and prognosis Dr. A. A. Smith contributes two cases (MEDICAL RECORD, February 13,

1886), and shows that abdominal aneurisms may become protected by inflammatory connective-tissue deposits, the result of local peritonitis. In this way the tumor-wall may receive support, rupture be prevented, and life prolonged. The thickened matted mass, however, sometimes obscures the diagnosis.

As for treatment, a ligation of the innominate artery, successful for a time at least, for subclavian aneurism has recently been performed by Mr. Bennett May, of London.

Dr. Berend (*Deut. Med. Zeitung*, 1886, No. 1) records the results of his successful treatment of a case, diagnosticated as aneurism of the aorta, by iodide of potassium. The drug was given in ordinary doses for two months.

Dr. Black (*The Lancet*) adds another to the long list of cases in which aneurism of the thoracic aorta was treated unsuccessfully by galvano-puncture. Two isolated needles were introduced, and a current of nineteen cells, increased to thirty, was passed for an hour. Ten days later the operation was repeated, the current being passed for half an hour. Nine days after this the operation was repeated for a third time. After this the patient died, and at the autopsy no coagulum was found to have been formed in the sac.

The introduction into the sac of a hollow ivory needle through which a coil of wire is passed, and this connected with a galvanic battery, has been recently alluded to in this journal.

The treatment of abdominal aneurism by compression, as advocated by Mr. Holmes, receives poor encouragement from a case reported by J. R. Lunn and F. L. Benham ("Med. Chirur. Trans.," vol. lxviii). The patient, a man thirty-two years old, had a pulsating tumor in the abdomen five to six inches long, and six to seven inches wide. It was movable, and pressure on the aorta lessened the pulsation. A tourniquet was applied for four and three-quarter hours; the tumor pulsated less and became smaller and harder, but the patient died in three days. On post-mortem examination, it was found that a part of the jejunum had been compressed and was gangrenous.

In *The Lancet*, July 10, 1886, Mr. J. A. Kelly reports a case of simultaneous ligature of the right subclavian and right common carotid for aneurism of the ascending arch. The operation was successful and the symptoms were improved. A point of interest was that a good deal of the operation was done under cocaine.

DOES GOOD PLUMBING GUARANTEE A SANITARY DWELLING?

Dr. E. Noeggerath describes, in the *Journal of Obstetrics*, a microbe of extraordinary vitality which he obtained from uterine clots in a case of puerperal fever. The microbe was cultivated and its peculiar mode of growth noted. It was considered to be the cause of the fever:

"1. Because blood-clots expelled during the course of puerperal fever do contain, if any, the identical microbe which is found in abscesses developed in other parts of the body, *i.e.*, the specific cause of the fever in each individual case.

"2. Because this microbe belonged to the class of bacteria called saprogenes, with which corresponds the type of fever that I have attempted to describe.

"3. Because the patient was under its influence before and during confinement."

The fever in question, which was not fatal, was remittent, low, and prolonged. It was considered to be symptomatic of sapræmia, *i.e.*, of absorption of decomposed lymph and gases, not of a micro-organism itself, as in septicæmia and pyæmia. The labor was conducted upon the most careful antiseptic principles, the room, furniture, and clothing being thoroughly disinfected, and sublimate injections being made at intervals during parturition. Yet, despite it all, the microbe appeared and set up the putrefactive change which caused the fever. This microbe was found, among others, on the stopper of one of the wash-basins. Yet as regards the plumbing of the house Dr. Noeggerath says:

"Before and after the fever the present owner of the house had one of our best experts to examine the plumbing work, and he received the satisfactory assertion that it was the best that could be had in our day; and still the house was poisoned from the water-pipes.

"Consequently, a so-called good plumbing, from an engineering point of view, is no guarantee of a sanitary condition of a dwelling."

THE MICROBE OF RABIES.

The announcement of the discovery of the microbe of rabies, by Mr. G. F. Dowdeswell, of London, is made in terms which appear to us to be far from satisfactory.

In the first place, we can only express our astonishment that Mr. Dowdeswell has found so little difficulty in obtaining material for experiment—his language indicates that a large number of dogs with rabies was at his disposal. Now we know that one scientist in Berlin has been waiting in vain for a single case of undoubted hydrophobia for over three years, and that Dr. Billings, of this country, has not succeeded in obtaining, since his return from his visit to Pasteur, in Paris, a single specimen of a really hydrophobic dog, dead or alive, although reported cases of rabies have been of frequent occurrence. If we, therefore, express a doubt as to the genuineness of the material readily found in abundance by some experimentalists, the skepticism is pardonable.

Again, Fol made the same announcement with equal confidence in 1885. Now the microbe of rabies of Fol and that of Dowdeswell are not only not identical but opposite in character. Clearly one must be in error; which, if either, is in the right?

Dowdeswell takes much pains to state that his microbe will not take the stain of certain dyes, but omits for the present to state what stain it will take. Why make a mystery of it?

Dowdeswell cannot find his microbe in the salivating glands. Now we know that the microbe, if it exists at all, is certainly in the saliva of the dog, as that is the immediate medium of contagion to man. This fact casts a serious doubt upon the value of the Dowdeswell discovery.

Dowdeswell's microbe of rabies is said to be a micrococcus, not very minute, and of the usual form. They are spherical bacteria, and are usually found in cases of a contagious nature and virulent affections.

A NEW SKIN DISEASE.

For several years Western medical journals have contained articles upon a distressing form of skin disease known by the various names of "The Scratches," "Mange," "Prairie Itch," "Michigan Itch," etc. In a recent issue of the *Medical Age*, Dr. J. E. Clark gives a tolerably systematic account of it.

The disease, in most cases, is ushered in without any prodromata, the first symptoms being itching and a papular eruption. The papules are at first very minute. If not aborted they become vesicular in places, "the acuminated elevation of the cuticle giving way to the orbicular, which, with an accumulation of lymph, clear and colorless, marks the vesicular stage. In this stage the severe itching is attended with considerable superficial heat and tingling of the part. In some cases the local inflammation runs high, and the surrounding derma is of a bright scarlet color, with a feeling of tension in the part affected."

The eruption always occurs on a portion of the body covered with clothing, the hands and face never being affected. It favors the arms, chest, abdomen, and thighs, and is never general. Small sores sometimes result from scratching; they become covered, however, with a scab, which desquamates, and all trouble in that immediate part is removed.

Some physicians regard the disease clinically as eczema papulosum. Dr. J. E. Engstad, of Grand Forks, Dak., describes a vegetable parasite which he believes to be the cause of the disease. "This organism," he says, "is found in all the layers of the epidermis, but its chief seat is in the corium. The organisms belong to the class of cryptogamia. The fungi appear like flattened, short, or elongated cells, with a very slender and tapering projection from each end, binding from five to twenty together in a chain, or as an oval cell, with from four to twenty hooklets projecting from its sides. A good and powerful microscope (600–800) will bring them into view. Their diameter is from twenty to thirty micromillimetres, and the hooklets and tapering appendage measure from ten to thirty micromillimetres."

According to the above accounts the disease is a vegetable parasitic affection. It is slightly contagious, and may run a long course, lasting even years, and causing the greatest distress.

The remedies suggested are very numerous. Internal treatment does little or no good, according to most writers, though arsenic and mercury are recommended externally, or ointments of mercury and sulphur, naphthol soap, followed by inunction of sulphur ointment with petroleum, lotions of carbolic acid and hyposulphate of soda, and frequent baths are recommended. The thorough and persistent application to the skin of parasiticides seems to be the basis of all the successful methods of treatment suggested.

THE CHOLERA.

The epidemic of cholera in Italy this year has attracted little attention and appears to have excited no alarm. This is doubtless because of the general belief that the disease has spent its force. Parisian papers of this month express the view that the cholera, although still extending slowly in towns of Northeastern Italy, is showing signs of decline. It has disappeared from Naples, no cases are reported in Venice, and the disease does not seem to be attacking any place with a great degree of virulence In the week ending July 21st, the total number of cases reported was 717, with 328 deaths. In the subsequent week the figures were reduced to 199 cases and 83 deaths.

The cholera has reached Austria, but has so far only attacked a few places, viz., Fiume and Trieste, on the Adriatic coast. The number of cases reported is only one or two daily.

FURTHER INVESTIGATIONS REGARDING SCARLET FEVER AND COW'S MILK.

Some new contributions have been made to this subject by Dr. E. Klein. It will be remembered that a few months ago an epidemic of scarlet fever was traced to a dairy, the cows of which were suffering from a disease (vesication and ulceration) of the udder and teats. Dr. Klein inoculated calves with virus from these cows, and thus showed that the disorder was a transmissible one. He also found in the tissues and secretions a micrococcus, which he cultivated, the organism resembling in its growth a streptococcus. Inoculation of pure cultures causes death in some animals, with marked lesions of the peritoneum and kidneys, the latter organs looking like the kidneys in scarlatinal nephritis.

It is very evident that our English brethren have got hold of a very important subject for investigation, but it appears to us that Dr. Klein, with his streptococcus, is very much afloat. Certainly this cannot be the parasite of scarlatina, as the investigations of Fraenkel and Fraudenberg show.

ACUTE CARDIAC DILATATION.

Much has been written of late upon the subject of acute dilatation of the heart occurring in the course of febrile diseases. That such dilatation does very often occur, and that it may give rise to marked and even fatal symptoms, is admitted. Systematic writers upon cardiac diseases, however, have not yet called sufficient attention to this matter. In Brainwell's classical work, and in Dr. Osler's excellent article upon cardiac diseases in Pepper's "System of Medicine," the point is hardly alluded to. Eichhorst says more about it, and gives some interesting illustrations.

An English physician, Dr. G. Coates, has recently contributed to the subject in an article on "Temporary Dilatation of the Heart occurring during the Course of Acute Disease" (*The Practitioner*, July, 1886). Dr. Coates reports four cases of acute dilatation, occurring during the course of a fever following mumps, in pneumonia, and in rheumatic fever. In all cases the physical signs were very decidedly marked, but in only one case were there notable symptoms of cardiac weakness. Dr. Coates concludes that acute temporary dilatation does occur, that it may not give rise to any symptoms, and that it is due to simple stretching of the under-nourished muscle. Murmurs are sometimes, but not always, heard, and the second sound in two cases was reduplicated.

Dr. Oliver Wendell Holmes sails from Liverpool on August 24th.

News of the Week.

Laparotomy for Gunshot Wound of Intestine.—Dr. W. T. Bull, of this city, has again successfully performed laparotomy for gunshot wound of the abdomen. A sailor, aged twenty-five, was shot in the abdomen, August 12th, at 7.40 P.M., the ball entering two inches below and to the left of the umbilicus. He was taken to the Chambers Street Hospital in a cab. Two hours later the abdomen was opened, the wound having been first explored and found to be penetrating. There were no symptoms of any inter-abdominal injury, the pulse being 94, respiration 24, and temperature 98°. Much blood was found in the cavity, the small intestine was pierced in two places, the sigmoid flexure in one, and there was a wound of the sigmoid mesocolon, from which copious venous hemorrhage took place. The operation lasted one hour and a half, and was well borne by the patient. There have been no bad symptoms since; no vomiting, but slight pain and a moderate tympanites. The pulse has ranged between 90 and 110, temperature between 99° and 100°. This morning (the fifth day) there was a natural movement of the bowels. In short, the *only* untoward occurrence is the appearance to-day, August 17th, of a small mural abscess.

The Late Dr. Frank H. Hamilton.—At a meeting of members and officers of the Society of Medical Jurisprudence and State Medicine, held August 13, 1886, Judge Hull presiding, it was

Resolved, That in the death of Dr. Frank Hastings Hamilton, its President, the Society has lost one of its truest friends, wisest counsellors, and most distinguished members; that we tender to his bereaved family and surviving friends assurances of our profound grief and sincere condolence in their great affliction; that his loss falls with especial severity upon this Society, over which he has so ably and impartially presided, to which he has contributed so much that is valuable, and from whom it had hoped to receive so much in the future; a man whose life has been characterized by all the social and domestic refinements; whose public and professional career has now the highest applause not only wherever the English language is spoken, but in foreign lands as well; whose devotion to surgical science and the relief of human suffering has wrought for himself tablets of imperishable fame, achieving for him the distinction of being one of the most eminent surgeons of his age, and at the same time conferring lasting honor upon his country. G. W. Wells, M.D., *Secretary*.

After the adoption of these resolutions it was unanimously resolved to hold a memorial meeting in honor of Dr. Hamilton, at the hall of the Academy of Medicine, 12 West Thirty-first Street, on September 9, 1886, at 8 P.M.

American Social Science Association.—The General Meeting of this Association for 1886 will be held at Saratoga, N. Y., from September 6th to 10th, inclusive, opening at 8 P.M., September 6th, with an address by the President, Carroll D. Wright, of Boston. The Department of Education will meet on Tuesday, September 7th; the Health Department on Wednesday, September 8th; the Department of Jurisprudence on Thursday, September 9th; and the Social Economy Department on Friday, September 10th. Papers on scientific subjects will be read by Drs. Grace Peckham, Holbrook Curtis, Valentine Mott, Wallace Wood, T. Munson Coan, all of New York.

Possibly Suicide.—English journals say that there is, unfortunately, evidence to the effect that, in a moment of depression, Dr. Moxon administered poison to himself, a note to this effect, clearly written just before the fatal act, having been found among the papers on his table, the reason assigned for it being the insufferable torture experienced by him from an organic disease with which he was afflicted.

Dr. Pasteur.—Pasteur is a doctor at last, having been given a degree *honoris causa*.

The Sanitary Era is the title of a new weekly journal devoted to the subject of sanitation. It is edited by William C. Conant and published in this city.

Dr. R. P. Howard having resigned the position of Vice-President of the International Medical Congress, to be held in Washington next year, Dr. J. A. Grant, of Ottawa, has been appointed to the same office by the Executive Committee.

Billroth's Operations on the Stomach.—In the last five years Billroth has performed operations on the stomach in 32 cases, with 19 fatal results. Out of 15 gastrectomies for cancer, there were 7 recoveries.

The Kentucky School of Medicine had the misfortune to lose by fire, on June 10th, its entire premises and outfit. It has already secured a new and commodious building, however, and the work of turning out the much-needed new doctor will go on. It takes more than an ordinary conflagration to interfere with a real live American medical college.

The Iowa State Medical Society.—According to the *Iowa State Medical Reporter* the last meeting of this Society was a success socially, but hardly so in other respects. We are told that the scientific work was far below the capacity of its members, and that there appeared some evidences of lack of harmony among them. Iowa is a large State, with over three thousand physicians, and it ought to support a good society.

The Late Dr. Walter Moxon.—In a most appreciative sketch of the character of Dr. Moxon, Dr. Samuel Wilkes says: "It is impossible in a few lines to portray the character of so remarkable a man as the late Dr. Moxon. His was no ordinary mind, and I feel sure there is not anyone unfamiliar with his conversation and writings who could form any conception of its wonderful acuteness and depth. When I say his was no ordinary mind, I intend rather to convey the idea that Moxon could in no way be summarized as an eminent doctor or distinguished scientist. He was thus totally different from his late colleague, Fagge. The latter had a most orderly mind, of great acuteness, and threw aside everything he could not clearly bring to reasonable proof. Of such composition are most of our best scientific men—men whose methods of procedure are clear to all; and, if one

judge by results, in the complete overthrowing of old modes of thought, must be regarded as possessing the best minds of the age. Moxon was not one of these; and, in one sense, might be called superior, for he belonged to a class of persons whose mental processes are beyond analysis; he was essentially a genius; he could elaborate doctrines out of a brain which was always dealing with the most subtle problems. Just as the poet is born and not made, so it is with every genius. Moxon was thoroughly outside all that was commonplace, and, touched as he was with a spark of the celestial fire, he could pour out his thoughts with a brilliancy which often amazed his hearers. Even over his patients he discoursed in a manner entirely his own, and it is to be hoped that there are many of his old pupils who have preserved some of his highly acute and philosophic sayings. His intellect was of that high order that whatever he touched he needs must have advanced, and therefore all his contributions to medicine were of the most valuable kind. It is possible that he might have excelled still more at the Bar, or in literature become another Carlyle."

Is Pasteur also to Collapse?—The announcement is made of two more deaths of patients who had been bitten by mad dogs and then inoculated by Pasteur. Among fifty-four persons bitten by mad wolves and inoculated by Pasteur, fourteen have now died, which is about the ordinary percentage. It seems impossible not to conclude that the Pasteur virus is at least impotent against mad wolves.

Postmaster or Doctor.—An Alabama physician has retired from practice temporarily in order to become postmaster.

Regulating Medical Practice in Iowa.—The State Board of Examiners, says the *Iowa State Medical Reporter*, held their first session under the new law on July 9th. Ten per cent. of the physicians of the State presented diplomas or certificates of practice. Six presented themselves for examination. There is a good prospect of a satisfactory enforcement of the law.

American Dermatological Association. — The tenth annual meeting of this Association will be held at the Indian Harbor Hotel, Greenwich, Conn., August 25, 26, and 27, 1886.

The Association of American Physicians.—The extraordinary course of the *Journal of the American Medical Association* in attacking The Association of American Physicians and Pathologists has, we hope, received a check through the following letter, sent to the *Journal* by Dr. James Tyson, Secretary of the Washington meeting. He writes: "Referring to the communications in your issues of the 24th and 3d ult., with regard to 'The Association of American Physicians,' it was with extreme reluctance, and only after recalling the fact that published matter of this kind becomes the source of history—history which in this instance would be erroneous—that I decided to write briefly the actual history of the formation of the society. *First*, the organization was altogether independent of, and prior to, the idea of a Congress of American Physicians and Surgeons. The orginal suggestion came more than three years ago, *not* from Philadelphia or New York or Boston, but from Toronto, Canada. It was based upon the feeling that such a society had become almost necessary in view of the fact that all departments of medicine, except general medicine and pathology, were represented in special societies devoted to their interests. Further, it was long after the arrangements for organization were essentially completed that the idea of a Congress of American Physicians and Surgeons was formulated by the American Surgical Association. *Second*, the Association was not formed in antagonism to the American Medical Association, and it was a matter of serious solicitude with some of the founders lest such interpretation should be put upon its formation; but this was not considered sufficient reason for giving up a plan which promised so much for medicine and pathology. So far as I know, no member who is also a member of the American Medical Association has 'forsworn his allegiance' to the latter, as is alleged by your Philadelphia correspondent. *Third*, in selecting original members for the 'active list,' it was desired to secure men who had been and still are active in furthering the interests of medicine and pathology, either as practitioners, teachers, or writers. That this was accomplished with reasonable success, when it is remembered that a certain number of vacancies are maintained for the present, will, I think, be conceded by the unprejudiced observer. *Finally*, with regard to the name chosen, a moment's consideration should satisfy the critic that the use of any other 'article' than the 'definite' would produce a ludicrous and impossible title. Such a title would be '*An* Association of American Physicians,' '*An* American Gynecological Society,' '*An* American Ophthalmological Society,' etc."

A Fortunate University.—Since 1879 the University of Sydney has received donations exceeding a million of dollars. One bequest, known as the Challis bequest, is expected to realize £200,000. The Macleay Natural History collection, another recent gift, is valued at £25,000, and a sum of £6,000 has been promised for the endowment of a curatorship in connection with it. For the purpose of founding a library a donation of £30,000 was made.

Separate Licensing Boards in Canada.—The *Canada Medical and Surgical Journal* says: "The advisability of establishing a Central Examining Board has now been fully entertained both by the Governors of the College and also by the general meeting of the profession. It will, therefore, doubtless come into force as soon as the necessary legislation shall have been obtained. The proposed composition is such that all interests seem to be fairly represented. The total number will be twenty, more than would be required, except for the absolute necessity for a double set of examiners, English and French."

A Case of Graves' Disease, due to nasal hypertrophy, is reported by Professor Hack, of Freiburg. On destroying the diseased erectile tissue of the nose with a cautery, the eye and heart symptoms and stricture disappeared. Professor Hack thinks that Graves' disease may be a reflex neurosis.

Reports of Societies.

British Medical Association.

FIFTY-FOURTH ANNUAL MEETING.

Held at Brighton, England, on Tuesday, Wednesday, Thursday, and Friday, August 10, 11, 12, *and* 13, 1886.

(DIRECT CABLE TO THE MEDICAL RECORD.)

(Continued from page 188.)

THURSDAY, AUGUST 12TH—THIRD DAY.

THE Association was called to order at 11 A.M. by the President, WITHERS MOORE, M.D., F.R.C.P., of Brighton, Surgeon to the Sussex County Hospital.

The first order of scientific business was the delivery of the

ADDRESS ON SURGERY,

by FREDERICK ABELL HUMPHRY, F.R.C.S., of Brighton, Surgeon to the Sussex County Hospital, who first referred to the mutual relation existing between medicine and surgery, shown in the fact that the one could not be practised successfully to the exclusion of the other; that the invasion of the field of surgery from a medical point of view is a necessity; that the invasion by the surgeon of fields heretofore regarded as exclusively medical has carried with it broader views with reference to the condition of the whole body. At one time the cranial cavity was looked upon as belonging wholly to the physician, and whenever its contents became involved in disease, save what was the result of direct violence, the physician was consulted. So it was with the thorax and abdomen. Only a few years have elapsed since it was regarded as chimerical to propose to explore the abdominal cavity by means now so freely practised by surgeons. The consequence was that physicians had so thoroughly familiarized themselves with the diseases of the contents of these three great cavities of the body that now it is doubtful if medicine has not done as much for surgery as surgery has done for medicine. That this mutual relation has been recognized has been shown by the fact that careful surgeons, in all cases surrounded by the least doubt, call to their aid the diagnostic ability of the skilled physician before applying the resources of their art.

The speaker then compared old with modern surgery, and here he was led to mention and to describe more or less in detail the advancements which had been made, not only in science, but in the application of its principles, aided by the marvellous discoveries of anæsthetics and the use of antiseptics.

As an illustration of an opportunity for further advancement, notwithstanding the great achievements already made, special reference was made to our present knowledge of visceral syphilis. Attention was then directed to the medical treatment of surgical cases. In many cases surgical operations failed to cure the patient because they were performed only as an aid to the physician, and the patients died because the surgeon failed to give them the medical treatment required to cure the disease that gave rise to the necessity for the operations.

In this respect provincial surgeons enjoyed advantages not vouchsafed to their apparently more highly favored brethren of the great metropolis; for, being general practitioners also, they were able to extend to their patients all the benefits which experience as physicians in private practice enabled them to impart.

The address was concluded by special reference to the advantages afforded by Brighton to scrofulous patients, and the benefit which surgical cases could obtain by reason of better nursing and the facilities for attending to the general system, hygienic and otherwise, than could heretofore be offered.

The address was listened to with marked attention throughout the entire delivery, and at its close Sir William MacCormac proposed a vote of thanks to Mr. Humphry, which was seconded by Mr. Wheelhouse, and heartily adopted by the Association.

AWARD OF PRIZES.

The gold medal for distinguished merit was presented to Dr. Edward Waters. This is the highest honor which the Association can bestow, and was awarded to Dr. Waters in recognition of his long, arduous, and at last successful labors in securing medical reforms.

The *Stewart* prize was awarded to Dr. Robert Cory, who had demonstrated on his own person the possibility of vaccinal syphilis.

The *Middlemore* prize was divided between Mr. Berry and Mr. Frost.

PRESENTATION OF AMERICAN DELEGATES.

NATHAN S. DAVIS, M.D., LL.D., of Chicago, President of the International Medical Congress, was presented to the Association, and spoke at some length with reference to Congressional matters. Sterling and most fitting were the words he used in memory of Gross and Flint, which drew from the sympathetic audience a hearty applause. He extended a cordial invitation to the members of the British medical profession to attend the forthcoming Congress.

DR. WILLIAM BRODIE, of Detroit, was introduced, and responded in a few well-timed remarks, which were received with cheers. Other delegates were introduced and spoke, and on motion by the President, seconded by Balthazar Foster, President of the Council, Dr. Davis and his colleagues received a vote of thanks for their unanimous expression of fraternal feeling toward the profession of the United Kingdom.

The Association then adjourned to meet on Friday, August 13th.

At 7 P.M. the General Association attended a public dinner—a sumptuous repast—followed by speech-making.

MEETINGS OF SECTIONS.

SECTION IN MEDICINE.

The Section met in the Music Room, and was called to order at 2 P.M. by the President, DR. H. BROADBENT, who delivered a short address, which was followed by the regular subject for discussion, entitled

ON THE EFFECTS PRODUCED BY GALL-STONES, WITH PARTICULAR REFERENCE TO SOME LESS KNOWN POINTS IN THEIR SYMPTOMATOLOGY.

W. Ord, M.D., F.R.C.P., of London, opened the discussion, which was continued by Dr. T. Churton, Professor Charcot, of Paris, France, and Dr. Sir Peter Eade.

The discussion pertained largely to some of those rare disturbances which are manifested by the nervous system.

GEORGE H. SAVAGE, M.D., then read a paper on

MENTAL SYMPTOMS WITH LOCOMOTOR ATAXY,

in which he referred to those peculiar mental aberrations sometimes seen in connection with chronic diseases affecting the nervous system, and which have been regarded as being close to the border-line of insanity.

C. H. RALFE, M.D., followed with a paper on

FUNCTIONAL ALBUMINURIA,

in which the arguments *pro* and *con* were lucidly set forth, leaving the hearer to conclude that the greatest safety for the patient consisted in giving him the full benefit of the doubt before deciding that his case does not present a serious aspect. That there were cases in which albuminuria was temporary had been fully demonstrated.

This paper was followed by one on

THE RELATIONSHIP OF UREA TO CERTAIN DISEASED PROCESSES,

by T. OLIVER, M.D., chiefly those affecting the digestive organs and the nervous system.

The Section then adjourned to meet on Friday.

SECTION IN SURGERY.

The Section was called to order by the President, JOHN ERIC ERICHSEN, F.R.C.S., F.R.S., of London, and the first paper was on

HEPATIC PHLEBOTOMY AND PUNCTURE IN HYPERTROPHIC CONGESTIONS OF THE LIVER,

by GEORGE HARLEY, M.D., F.R.S. The operation was regarded as a feasible one under proper antiseptic precautions, and one likely to be attended by permanent benefit when successfully performed.

J. K. THORNTON, ESQ., then read a paper entitled

THE SURGERY OF THE LIVER,

in which all the known operations upon this organ were fully considered.

A. WILLETT, ESQ., followed with a paper on

CHOLECYSTOTOMY,

and HOWARD MARSH, ESQ., of London, reported

A CASE OF ABSCESS OF THE LIVER OPENED BY INCISION,

in which the patient made a good recovery.

LAWSON TAIT, ESQ., then read, for Dr. Mackay, of Huelva, a contribution to

THE SURGICAL TREATMENT OF GALL-STONES.

These papers were discussed together, and the discussion was participated in by a large number of members.

DR. FITCH OWEN, of Nova Scotia, read a paper on the use of

THE DOME-TROCAR

and associated instruments in paracentesis, aspiration, transfusion, ovariotomy, and tunnelling the enlarged prostate.

EDMUND OWEN, ESQ., followed with a paper on

PSOAS ABSCESS,

in which he discussed the questions when and where to evacuate it under antiseptic precautions.

WILLIAM ADAMS, ESQ., of London, read a paper

ON THE TREATMENT OF CONGENITAL DISPLACEMENT,

which is the so-called congenital dislocation of the hip-joint. His method is by long-continued recumbency and extension, and he exhibited his new extension couch.

The Section then adjourned to meet on Friday.

SECTION IN OBSTETRICS.

The Section was called to order by the President, ALFRED MEADOWS, M.D., of London. The first paper was read by W. T. LUSK, M.D., of New York, and entitled

THE PROPER MOMENT FOR THE PERFORMANCE OF GASTROTOMY IN ABDOMINAL PREGNANCY.

It was discussed by Mr. Lawson Tait, of Birmingham, Eng., Dr. H. P. C. Wilson, of Baltimore, Md., the President, T. R. Jessop, T. M. Dolan, A. W. Edis, and Dr. Lusk.

D. BERRY HART, M.D., then read a paper, in which he reported a successful case of

ABDOMINAL SECTION FOR RUPTURED FALLOPIAN TUBE FŒTATION.

It was accompanied by a microscopical examination of the part of the tube removed, which was especially interesting with reference to certain histological and pathological questions.

J. H. AVELING, M.D., reported a case of

EXTRA-UTERINE GESTATION ARRESTED BY ELECTRICITY.

The subject was discussed by C. J. Wright, M.R.C.S., of Leeds; W. Gill Wylie, M.D., of New York; Lawson Tait, Esq.; Drs. W. T. Lusk and H. T. Hanks, of New York, and several others.

DR. RANNEY, of Michigan, read a paper on the

TREATMENT OF MASTITIS,

which was discussed by several members, and was followed by a paper by DR. BEVERLEY, in which twenty cases of

EMMET'S OPERATION

were detailed. This gave rise to discussion, participated in by Drs. Gordon, Kelly, and Wylie, after which the Section adjourned to meet on Friday.

SECTION IN THERAPEUTICS AND PHARMACOLOGY.

The Section was called to order by the President, DR. T. LAUDER BRUNTON, of London, and PROSSER JAMES, M.D., of London, read a paper on

LOCAL ANÆSTHETICS.

This was followed by a discussion on

ANALGESICS,

which was opened by DR. SPENDER, of Bath, and continued by Brown-Séquard, of Paris, Liebreich, of Berlin, the President, and E. Mackey, M.D.

MORTIMER GRANVILLE, M.D., read a paper on

THE RELIEF OF PAIN BY MECHANICAL VIBRATION OR PERCUSSION,

which was followed by one on

THE THERAPEUTIC EFFECT OF COCAINE IN OPHTHALMIC PRACTICE,

by W. H. JESSOP, M.B.

Stephen MacKenzie, M.D., then read a paper on

THE VALUE OF CANNABIS INDICA IN CERTAIN CASES OF HEADACHE.

It was regarded as an efficient remedy, especially in some forms of migraine.

The Section then adjourned to meet on Friday.

Friday, August 13th—Fourth Day.

The Association convened at 10 A.M., and heard the

ADDRESS IN PUBLIC MEDICINE,

given by E. D. Mapother, M.D., Consulting Officer to the City of Dublin.

It related largely to the status of the medical profession in Ireland, and to its work. Epidemics and alcoholic diseases were of infrequent occurrence in that country. Among the humbler rural classes and the common middle classes the sick poor in Ireland were better cared for than in any other country—thanks to the Medical Charities Act. College hospitals for infectious diseases were needed. Provident dispensaries were unknown in Ireland, except a few in large towns. The county infirmaries were well managed, and there was no city in the world where so many hospitals existed in proportion to the population as in Dublin, where there were ten hospitals.

The speaker then referred to the two professional occupations suitable for women, namely, mechanical dentistry and dispensing medicines. With reference to allied sciences, there was no teaching of veterinary medicine in Ireland.

On motion by Richard Patrick B. Taaffe, M.D., of Brighton, seconded by Surgeon-General Moore, Dr. Mapother received the hearty thanks of the Association, for his able address.

CONCLUDING MEETING—HONORARY MEMBERS, ETC.

The concluding general meeting was held at 4 P.M., and at 8 P.M. a brilliant reception was given by the Mayor of Brighton.

At the concluding meeting Drs. N. S. Davis, of Chicago, John S. Billings, of Washington, J. A. Grant, of Ottawa, and Kingston, of Montreal, were elected honorary members.

After the reading of several reports from standing committees, on medical reform, parliamentary bills, scientific grants, collective investigation, etc., and the adoption of the usual votes of thanks to the President, citizens, etc., the Association adjourned.

The attendance during the annual meeting numbered nearly sixteen hundred.

On Saturday, August 14th, numerous excursions were given, and thus closed one of the most successful meetings in the history of the Association.

MEETINGS OF SECTIONS.

SECTION IN MEDICINE.

Dr. Radcliffe Crocker gave a demonstration

ON THE REMOVAL OF HAIR BY ELECTROLYSIS.

This was followed by a paper on

THE ETIOLOGY OF RHEUMATISM,

by A. Mantle, M.D., in which the author considered his subject from the bacterial standpoint, and exhibited specimens of the micro-organism he had found in rheumatism.

Dr. Haycraft then read a paper on

THE RELATION OF COAGULATION OF BLOOD TO DISEASE,

in which he made special reference to the more modern views concerning the exact factors in the process.

A paper on a cognate subject, and entitled

INADEQUATE TREATMENT OF ANÆMIA,

was read by Sir Dyce Duckworth.

Dr. Radcliffe Crocker also read a paper on

RECURRING ECZEMA,

which was followed by one

ON COMPRESSED AND RAREFIED AIR,

by A. Gamgee, M.D.

SECTION IN SURGERY.

Mr. Erichsen, President, called the Section to order at 11 A.M., and Victor Horsley, of London, read a paper on

THE ADVANCES IN THE SURGERY OF THE CENTRAL NERVOUS SYSTEM,

which he illustrated by means of photographs and the lime-light. The paper was one of the most interesting presented to the Association, and was discussed by Professor Charcot, of Paris, and J. Hughlings Jackson.

Bruce Clarke, Esq., and W. E. Steavenson, M.D., read papers on

THE EMPLOYMENT OF ELECTRICITY IN THE TREATMENT OF DISEASES OF THE URINARY ORGANS.

Reginald Harrison, Esq., of Liverpool, read a paper on

URETHRAL STRICTURE,

in which he set forth the advantages arising from the treatment by internal and external urethrotomy combined.

Noble Smith, Esq., read a paper on

OBSCURE DISEASE OF THE SPINE

pertaining to both bony and soft structures, and its relation to severe surgical injuries.

Sir William Stokes, of Dublin, followed with a paper on

ACUTE MYXŒDEMA OCCURRING SOON AFTER THE REMOVAL OF THE THYROID BODY.

Walter Whitehead, Esq., reported three hundred consecutive cases of

HÆMORRHOIDS CURED BY EXCISION,

thus exhibiting a remarkable surgical success.

S. Benton, Esq., read a paper on

FISTULA IN ANO,

in which he directed special attention to the horse-shoe variety, and its radical cure.

This was followed by a paper on

THE SURGICAL TREATMENT OF ACNE AND LUPUS,

by James Startin, Esq., who reviewed the methods by caustics, the use of the actual cautery, and by excision, puncture, etc.

THE SURGICAL TREATMENT OF CERTAIN TUMORS OF THE NECK,

was the title of a paper read by F. B. JESSETT, ESQ., after which the Section adjourned.

SECTION IN OBSTETRICS.

The subject for discussion was

REMOVAL OF THE UTERINE APPENDAGES.

The discussion was opened by Dr. Savage, of Birmingham, continued by Dr. More Madden, of Dublin, Dr. Imlach, of Liverpool, Mr. Lawson Tait, of Birmingham, and others. The tenor of the discussion was like that unto which reference can be made in nearly all the current medical periodicals of the day.

J. W. BALLANTYNE, M.B., of Edinburgh, exhibited

SPHYGMOGRAPHIC TRACINGS IN LABOR AND THE PUERPERIUM,

which was followed by a paper on

THE USE OF STEM PESSARIES,

by J. GORDON BLACK, M.D., of Harrogate.

DR. T. M. DOLAN then related several obstetric experiences, and made observations on the cases reported.

DR. A. W. EDIS read the last paper, which was entitled,

CASES ILLUSTRATING THE DIFFICULTIES OF DIAGNOSIS IN GYNECOLOGICAL PRACTICE.

Judging from the errors that have been made, all such cases are worthy of special consideration.

MISSISSIPPI VALLEY MEDICAL SOCIETY.

Twelfth Annual Session, held at Quincy, Ill., July 12, 1886.

THE above Society met on July 12th, DR. ARCHIBALD DIXON, of Henderson, Ky., President, in the chair; DR. E. B. MONTGOMERY, of Quincy, Secretary *pro tem.*

DR. H. M. LANE, of Carthage, Mo., read a paper on

YELLOW FEVER IN BRAZIL.

The Doctor had been on the ground, and related his own experience and observation in dealing with this disease by Freire's method. He gave in detail the manner of preparing the virus for inoculation, and recommended that this Society should memorialize Congress, asking the appointment of a committee to investigate this method, with a view to introducing it into this country.

DR. LOUIS BAUER, of St. Louis, presented a patient on whom he had performed laparotomy for symptoms of ileus. He found

AN ABSCESS IN THE LIVER,

from which he drew off a quart of pus, then opened more freely and washed out the cavity with an antiseptic fluid. A portion of the gall-bladder sloughed out, and the large intestine was perforated, but no constitutional disturbance resulted. The Doctor believed with Lawson Tait that laparotomy was frequently useful. Discussed by Drs. Beard, of Vincennes, Ind., and Bernays, of St. Louis.

DR. F. W. BEARD, of Vincennes, related a case where he had observed

SEMINAL EMISSIONS AT DEATH FROM HANGING.

DR. A. H OHMANN-DUMESNIL, of St. Louis, read a paper on

LUPUS ERYTHEMATOSUS

and reported a case. The patient was a farmer, aged fifty-two, who had always been in good health. The lupus involved the dorsum of the hand and arm, and occasioned no complaint on the part of the patient. He illustrated the pathology of the disease by several very fine microscopical specimens. As to treatment, he used a concentrated solution of lactic acid. Photographs of the case were also shown.

DR. ROBERT BARCLAY, of St. Louis, in a paper on

NOISES IN THE HEAD AND EARS,

devoted especial attention to the pathological conditions giving rise to them and their treatment.

The President, DR. ARCHIBALD DIXON, of Henderson, Ky., read a paper entitled

PERINEAL LACERATIONS.

He greatly favored Simon's method of repair.

DR. FRANK R. FRY, of St. Louis, read a paper on the "Etiology of Chorea." He advocated the neurotic theory and opposed the embolic. The exciting causes he thought to be various.

On motion of DR. DUDLEY S. REYNOLDS, of Louisville, the Society adopted the Code of Ethics of the American Medical Association.

DR. HENRY M. LYMAN, of Chicago, read a paper on the

DISCOVERY OF ANÆSTHETICS,

going thoroughly into the history of the subject.

DR. DUDLEY S. REYNOLDS, of Louisville, read a paper on

OPTICAL DEFECTS AND THEIR CORRECTION.

He exhibited an instrument for the measurement of the lenses. Its recommendation was simplicity.

DR. J. L. GRAY, of Chicago, showed a stomach-pump, with siphon attachment, which could be useful in introducing aliment or washing out the stomach.

DR. E. B. MONTGOMERY, of St. Louis, read a paper entitled

THE THERAPEUTICS OF HOT WATER.

He detailed its uses in a great variety of conditions.

This paper was extensively discussed.

DR. L. H. COHEN, of Quincy, read a paper on "Electro-Therapeutics."

DR. J. N. LOVE, of St. Louis, read a paper on

ARTIFICIAL ALIMENTATION,

in which he discussed especially the absorptive power of the rectum.

Officers were elected as follows:

President—I. N. Love, M.D., St. Louis.

First Vice-President—Joseph Robbins, M.D., Quincy.

Second Vice-President—Jacob L. Geiger, M.D., St. Joseph, Mo.

Third Vice-President—T. B. Harvey, M.D., Indianapolis.

Secretary—J. L. Gray, M.D., Chicago.

Treasurer—A. H. Ohmann-Dumesnil, M.D., St. Louis.

Assistant Secretary—Edward Alcorn, Houstonville, Ky.

DR. AMOS SAWYER, of Hillsboro, Ill., read a paper on

THE THERAPEUTICS OF SUBNITRATE OF BISMUTH AND ASCLEPIAS TUBEROSA.

The author opened with the assertion that acology had been inexcusably neglected in our Society proceedings. The author thought that one of the principal therapeutic effects of bismuth was its power to coagulate mucus. He had used the subnitrate of bismuth to coagulate the mucus in throat and nasal troubles.

In the tormina of dysentery, so distressing to the patient, the fluid extract of asclepias tuberosa, in teaspoonful doses, every two hours. A warm infusion of the fresh root also acts like a charm. In drachm doses every two hours it relieves the pain of acute muscular rheumatism in from six to eight hours; also the severe pains of pneumonia are relieved by it. Asclepias tuberosa is certainly a sudorific anodyne, and occasionally, through an idiosyncrasy, an emetic.

Dr. A. C. Bernays, of St. Louis, reported an operation for

LIGATING BOTH VERTEBRAL ARTERIES

in a case of epilepsy. The patient, a boy, aged twelve years, had had fits for seven years, sometimes over one hundred per day. Occasionally free intervals of several weeks. No hereditary encumbrance, no physical infirmities; well developed and tall for his age. Both arteries were tied. The ligature of the artery on the right side was very tedious, on account of venous hemorrhage from the perivertebral plexus, and on account of an abnormal course of the artery. It was but half the normal size, and skipped the sixth vertebra, running toward the median line to enter some vertebra higher up. This operation lasted about two hours. The left vertebral artery was tied, just as it entered the transverse process of the sixth cervical, in the usual way. It was somewhat larger than was suspected. Only ten minutes were required for this ligature. The incision was made to the outside of the external jugular vein, parallel to the rear border of the sterno-cleido-mastoid muscle, beginning half an inch above the clavicle, and extending 2.5 inches upward. The reporter made anatomical demonstration, and showed that the artery could be tied as it passes over the massa lateralis of the atlas, or even between any two vertebræ, after clipping out that part of the transverse process which corresponds to the head and neck of a rib with bone nippers. The essayist showed that the operation was not nearly so difficult and dangerous as would be supposed, judging from its anatomical relation and depth. The case did well; the wounds healed kindly, and there were no spasms since the operation up to the time at which the boy left the hospital for his home. The pulse ran up to 180, and the respirations to 58 per minute, immediately after the operation, and only returned toward the normal condition very slowly. The temperature was nearly normal on the second day. This remarkable height reached by pulse and respiration is a most interesting observation. It can be accounted for by the following reasoning, based on physiological facts: The medulla oblongata receives almost its entire blood-supply from the vertebral arteries. The pneumogastric nerve-centres are located in the medulla oblongata, near the calamus scriptorius. By cutting off the direct blood-supply the inhibitory centres are deprived of proper nourishment, and their action impaired. Therefore we can readily understand that the accelerating centres of the sympathetic held full sway until the collateral circulation was more or less perfectly established.

The reporter gave statistics in regard to the operation, which he thought was very much neglected in this country, in spite of the encouraging experiences of Alexander, of Liverpool, who had cured, or benefited, more than half of his cases.

The Doctor also showed a post-mortem specimen, a lady who had died from rupture of the cyst in

EXTRA-UTERINE PREGNANCY,

and consequent hemorrhage. The specimen showed a double uterus, with the fœtus in the left Fallopian tube.

A very enjoyable reception was given at the residence of Dr. R. W. McMahon.

The next meeting will be held at Crab Orchard Springs, Ky., the second Tuesday in July, 1887.

Roman Law and Medical Practice.—The Roman laws ordained, says Montesquieu, that physicians should be punished for neglect or unskilfulness. In treatment, if the physician was a person of any fortune or rank, he was condemned to deportation; but if he was of a low condition in society he was put to death, which was rather hard on the said physician of low condition.

A Cut in Time saves nine.

Correspondence.

LITHOLAPAXY IN BOSTON.

To the Editor of The Medical Record.

Sir: Under the heading "Operations for Stone in the Bladder" the Philadelphia *Medical News* of June 19th last, in an editorial, presents some views on the outlook for litholapaxy which are in a measure discouraging. The article states that "this method is practically applicable only to calculi of moderate size, and requires a degree of skill and experience on the part of the operator which cannot always be found. The consequence has been a more frequent return to cutting operations than was expected in view of the earliest achievements of litholapaxy." Since the introduction of Professor Bigelow's improvements in the method of crushing and evacuating stone in the bladder, no case has presented itself at the Massachusetts General Hospital which has, on account of the size or hardness of the stone, necessitated resort to a cutting operation. Practically the question of size is not to be considered, since any stone small enough to admit of some portion of its circumference being seized between the blades of the lithotrite can, providing it is not too hard, be successfully crushed and evacuated. The hardest form of calculus is that composed of oxalate of lime. In August last Dr. Beach removed, at the Massachusetts General Hospital, a stone of this character weighing 34.68 grammes. As is always done here when the urethral orifice is not up to the normal calibre of the remainder of the canal, the meatus was cut preparatory to the introduction of the largest-sized lithotrite. The stone was readily grasped, but only cracked after several attempts. Each fragment had to be crushed with the screw. Stones of this character are frequently considered as being beyond the scope of the lithotrite, and are removed by a cutting operation. The eight years during which Professor Bigelow's improvements have been in practice here have evidently not been enough to introduce them thoroughly elsewhere. The evidence which the clinic at the Massachusetts Hospital has thus far furnished would seem to show that litholapaxy must only be abandoned when a stone is diverticulated, or the urethra not sufficiently developed, as in children. Numerous cases are reported where enormous prostate hypertrophy prevented complete crushing, and the stones had to be cut for. Dittle and Bois each report a case where, owing to an anchylosed, strongly flexed, adducted, and inward rotated thigh, the lithotrite could not be used.

Boston.

THE TREATMENT OF IVY-POISONING.

To the Editor of The Medical Record.

Sir: In an editorial on the subject of rhus-poisoning, in The Record of July 31st, the statement is made that specifics for this affection do not in reality exist, and that the most that can be done is to palliate the symptoms, and, perhaps, shorten the period of the inflammation. I am convinced that in this you are mistaken, and that in bromine we have a specific which, when properly applied, will in every case cut short the attack within twenty-four to forty-eight hours after the first application.

I have used it now in nearly a hundred cases with this invariable result, and many of my medical friends have had the same experience, while I have yet to hear of a single unsuccessful trial. I have used it in cases of great severity, and also in cases which had long resisted treatment. Once during my service in the navy I was stationed where there were some five hundred recruits, who spent a good deal of their leisure time upon a tract of ground where the *rhus radicans* abounds, so that I had a number of new cases of poisoning each day. At this time an officer joined us who had been suffering for five weeks. The application cured him at once. Being un-

usually susceptible to the action of the poison and seeing the promptness of the cures daily effected, he conceived the idea that by having the whole skin affected and then cured, he might purchase immunity from future attacks. He therefore gathered the leaves of the plant, bruised them, and rubbed the juice upon the entire surface of the body. I saw him in about sixteen hours after the application. He was standing naked in the middle of the floor, unable to sit or lie, or bear any clothes to touch him. He was greatly swollen, especially about the genitals and face; his features were nearly obliterated, and his eyes were buried by the tumefaction. He was suffering greatly from pain and the discomfort of his condition. His temperature was elevated two degrees, and his pulse was 110°. I caused the application to be made at once to every part of the body. Relief was almost immediate. Pain and swelling began at once to subside, temperature became normal; in twenty-four hours he was able for duty; in forty-eight hours every trace of his experiment had vanished. Not a single vesicle formed. (This case was reported in 1883, before the Dakota Medical Association.)

I cannot but believe that my constant success in such a large number of cases spread over twelve years' practice and treated in the West Indies, the Pacific Islands, California, Dakota, and elsewhere, is due to the specific power of bromine. At all events my experience shows an extraordinary result, and seems to justify my once more urging the agent before your notice. It was first presented in THE RECORD of May 20, 1878. The formula used is:

℞. Bromi..... gtt. xv.
Ol. olivæ..... ℥ j.

M. S.—Apply freely to poisoned surface four times a day. Wash with warm water and castile soap twice a day.

The solution should always be fresh, as it deteriorates by evaporation even when cooked.

Respectfully yours,

S. A. BROWN, M.D.

SIOUX FALLS, DAK., August 4, 1886.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Dermatitis Venenata—the inflammation produced by poison-oak or ivy, is claiming attention. It isn't infrequent with us; is most times obstinate, always annoying and painful. Have myself been a victim more than once, and know experimentally the exquisite torments of the affection, and the inefficacy of much of the treatment as well.

Was suffering from a particularly trying attack some years ago; both arms were well-nigh raw to the shoulders, and there is no adjective to qualify the torment I endured. Everything had failed me, and in my desperation I thought of mur. tinct. iron locally—my clearest idea being that the smart of the remedy might at least obscure that of the disease. In this I wasn't disappointed. I incautiously mopped both arms rapidly and thoroughly. For twenty or thirty minutes my sensations were varied and lively; after which, the disturbance subsiding, I decomposed the tinct. with a wash of soap and water, completing the treatment with a dressing of olive oil. Relief was immediate and complete, desquamation ensuing within a few days.

Have used the tinct. in numerous instances since, and with uniform results. More than one application has rarely been necessary, and when so, only I think because the first was not thorough. Within a few days my own son came home to me with both feet and ankles so inflamed from this poison as to practically disable him. It was of two weeks duration, the usual remedies giving no relief. One thorough application of the tinct. was all that was required.

In children, or nervous, susceptible patients, where the abrasions from inevitable scratching are extensive, it is well to advise them of the sharp, but transient, burning attending its use. Either so, or apply it gradually, giving time for accommodation of parts, etc. I use it full strength, and as we do iodine.

There is nothing *specific* in the action of the drug; nor do I use it empirically. This form of dermatitis differs from others of its class only in its source or origin—the rhus family being responsible here. The condition is one of inflammation of the derma, probably just the same as in traumatism, the application of heat, cold, etc., and characterized, in degree, by the usual *neber, caler, doler*, with intolerable itching as a harrassing climax. The usual local sedatives and mild astringents do not answer—their action is too superficial. Cauterants, of course, are out of the question. But something from the border-line between the two—from among the stronger astringents, of which the mur. tinct. is fairly typical—meets the demand, and accords with principle. The use of it, too, is free from the objection to carbolic acid (probably as efficient in equivalent strength) in that neither possible idiosyncrasy obtains, nor is there local or general trouble to be apprehended from its employment.

I think any patient thus racked may rather confidently expect prompt relief from the thorough use of the tinct. as above, in any stage. A little pluck to endure the stinging pain for a few minutes is the only prerequisite. Short acquaintance with the affection will render any change welcome. Very respectfully,

A. G. BROWNING, M.D.

MAYSVILLE, KY., August 12, 1886.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Spirits of turpentine applied, if possible, before the vesicles rupture, is an efficient application in rhus-poisoning. I am, sir, Very respectfully yours, etc.,

T. E. WILCOX, M.D.,
Assistant Surgeon U. S. Army.

WASHINGTON BARRACKS, D. C., August 6, 1886.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I was somewhat disappointed in readinng your editorial in THE RECORD of July 31st on "The Treatment of Rhus-Poisoning"—disappointed, because I expected to find, somewhere in the body of the article, something confirmatory of the virtues of a solution of the bichloride of mercury as a topical remedy in the therapy of this dermatitis.

I can assure you of the specific virtues of the bichloride in the treatment of rhus-poisoning. The poison-oak abounds in this section, and I have had repeated opportunities for making observations with various remedies, and have abandoned all, except a ten to twenty grain solution of corrosive sublimate, as it has proved to be a specific in my hands. I have kept no record of cases so treated, but can state most positively, that if applied on the second or third day of invasion, that a cure will follow as rapidly as a cure could be expected to obtain. In other words, the bichloride stops the inflammatory action at once, and resolution proceeds from thence to a complete relief. For purposes of safety, I sometimes repeat the application a second time, but in the large majority of cases, a single one suffices for a complete and immediate cure.

WILLIAM B. DAVIS, M.D.

GRAYSVINE, FARRAGUT COUNTY, TEN.

SOME FURTHER REMARKS ON THE DEATH-PENALTY AND METHOD OF INFLICTION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I was much interested in an article appearing in THE MEDICAL RECORD of July 24th, by Dr. Wooster Beach, of New York, in regard to the death-penalty and methods of infliction.

Dealing as it does with so serious a matter, it cannot be other than a question of extreme importance; a question of importance from various stand-points—popular, moral, medical, and legal; let me combine the last two, medico-legal. The first two can be passed by as being outside the pale of discussion in a purely medical journal, while the last two may be retained as presenting grounds for general remarks, since they so often are found hand in hand, especially in questions like the above.

In this country, as is well known, hanging is and has been for some time the method of inflicting the death-penalty, and although on many occasions it has been severely attacked, and at times has, as in Maine, Iowa, and Wisconsin, been abolished, yet only to be resumed, it now remains the accepted form of punishment, the chief reason of this being, no doubt, the wholesome dread which such a method of death holds over the heads of those who are tempted to commit such crimes as demand capital punishment. Now, so long as this fear actually exercises and brings about a marked decrease in the percentage of such crimes, no doubt this form of inflicting the death-penalty, or one equally efficacious, will be retained, however revolting such a death seems to the public mind, especially when accompanied by such awkward and disgusting blunders as we frequently see laid at the doors of those whose duty it is to inflict the death-penalty!—a seeming relic of barbarism, or a relic of barbaric customs prolonged into the nineteenth century!

Dr. Beach in his article has enumerated various other forms of death, some of which have long been used in other lands, as the guillotine in France, garroting in Spain, etc., but he speaks of one which I desire especially to refer to, viz., death by the use of an anæsthetic (chloroform or ether).

Now it is quite generally known, I apprehend, how easy and painless a death can be produced by the use of this powerful agent (chloroform), and right here it may be remarked how strange it is that individuals bent on self-destruction will adopt all sorts of horrible methods to accomplish their object, as cutting the throat, shooting, the use of violent poisons, and the very method we have been speaking of—hanging—rather than drop into oblivion by inhaling a few drops of chloroform from the midst of a cluster of heliotrope, as a famous novelist has graphically put it.

To return to the use of chloroform as a means of inflicting the death-penalty.

How often has the experimenter and physiologist, while eagerly at work in his laboratory, attempting to unfold some new truth or striving to clear up some not yet quite decided or fully understood question of function or action of organ or nerve, exclaimed, "Oh, if it were only possible for us to conduct our examinations on man himself!" But up to the present time he has sighed in vain, and has gone on doing the best he could, confining his researches to cat, dog, or monkey, being obliged to judge only by analogy or approximate similarity found existing in the ascending grades of animal life.

And now, without further introduction, comes my plan, and though it may seem very visionary at the present time, let it be remembered that "great oaks from little acorns grow."

Let every criminal sentenced to suffer the extreme penalty of the law be delivered over to our most accomplished experts in comparative anatomy and savants in medicine; have these gentlemen authorized to experiment as they shall see fit upon such criminals, only that all such experimentation shall be made in the presence of a committee of medico-legal officers chosen by the Government, whose duty it shall be to see that the full letter of the agreement be carried out, viz., that from the time the culprit passes into the hands of the scientists, until his death shall have taken place, he shall suffer no pain or distress, other than that incidental to passing under the influence of the anæsthetic, and after his death the remains shall be disposed of as in the case of hanging by the sheriff.

The wished-for insensibility shall be initiated by ether if thought proper, and the individual shall never be permitted to recover consciousness, or any condition approaching it, again; he shall be kept under the influence of the anæsthetic a sufficient length of time to insure the success of the experiment, or such length of time as those present shall think advisable, and then the anæsthetic shall be pushed to the extreme, and so bring to a close the life which was condemned because it took life.

What a splendid field of investigation and research, for denial or corroboration of those principles already supposed to be clearly understood, as well as the certainty of discovering new truths, would be opened to the medical profession, and through the profession to mankind in general!

To be sure, we could not make certain experiments on the body of the criminal while unconscious, and then allow him to recover, so that we could await the results, as in the case of animals; nevertheless, that a vast deal could be accomplished no one will deny.

Now, as regards the influence such a method of punishment would have on those tempted by one cause or another to render themselves liable to the death-penalty.

If we can judge at all by the horror which people in general have of vivisection, we should have no need of a death-penalty for a long while!

The would-be murderer, having in view only the knowledge of vivisection as held by the public mind, would not be very prone to run the risk of such a terrible ending should he be apprehended; and yet when a criminal did suffer death in the way above suggested, he really would be executed by the most painless method possible.

In this way two great things would be accomplished: 1st, There would be fewer murders by far; 2d, when one did occur, a compensation for the life that was lost might be found as a germ long hidden, its place of concealment being in the body of the assassin, a germ which in time to come would develop into a boon of priceless value to the sons of men.

J. B. Thornton, Jr., M.D.

Scarboro, Me.

WHAT CAN WE CURE?

To the Editor of The Medical Record.

When one takes up a new work on the practice of medicine and contrasts it with one written a century ago, he finds far more diagnosis and pathology, but less therapeutics. A more accurate account of the part played by drugs in the cure of disease has entombed a good many specifics. Whole classes of remedies are left out of modern therapeutics.

Others, while retaining a feeble existence, are destined to go sooner or later.

Lithontriptics to dissolve stone in the bladder are defunct; emmenagogues are in a decline; expectorants show evident weakness.

That any drug is possessed of power, *per se*, to produce the menstrual flow, has ceased to be believed by the profession.

Dr. Meigs called emmenagogues "hen-persuaders." A patented hen's nest was so constructed that the eggs would drop out of the nest so soon as layed, whereupon the hen would lay again. There was no end to the number of eggs that could be produced in this way.

Expectorants were believed to possess some inherent power of hunting for the lungs, and loosening adhesive mucus from the bronchial tubes. Some doctors still believe that squills, ipecac, and senega possess some power to get phlegm out of the lungs.

These so-called expectorants once had much reputation in the treatment of pneumonia.

They were supposed in some unknown way to get the exudation loosened and "spit up."

This is now a vain hope. There is not the slightest evidence that any known drug has any such special affinity for the lungs.

Some men are always in a fog in the treatment of pneumonia.

Most of the remedies in use for this malady have harmed the patient more than the disease.

> "Like blind men fighting in the dark,
> They never fail to miss the mark;
> When death doth fail, the doctor's sure
> To meekly stand and claim the cure."

The better class of physicians are not expecting honors from prescriptions. Flint was no drugger. Holmes is a medical sceptic. Bennett, before whom the dosers and druggers quail, says there are but four drugs known whose effects are unquestionably beneficial in particular diseases. They are: 1, Quinine in ague; 2, pitch ointment in psoriasis; 3, male shield fern in tape-worm; 4, sulphur ointment in scabies.

In the days of our ignorance we hoped to shorten the course of measles, scarlet fever, small-pox, and typhoid fever. To-day we count on our fingers to measure the day of crisis—of typical endings. Acute ophthalmia, superficial erysipelas, and sporadic flux are found to be self-limited. Nitrate of silver, sugar of lead, sulphate of iron, iodine, et cetera, have all lost their reputation for limiting the spread. Whatever is used, the spreading ends in three or four days. Acute ophthalmia ordinarily ends in fourteen days, doctored or undoctored. Collyriums have made seas of briny tears, but performed no cures.

The land rings with anthems sung to the doctors who have cured sporadix flux. The eclectic and the homœopath have divided honors with the regular physicians in the cures. Most of the patients go abruptly into convalescence on the fourth day. Even that endemic disease, gonorrhœa, which every ignorant and dishonest doctor will promise to cure in five days, Trousseau declares to be the despair of the physician.

Diday says syphilis is cured by the grace of God.

When we cut out the confessedly incurable and the self-limited complaints, we have not got much to work on. The specialist claims what is left. Drugs intelligently used, I doubt not, have often greatly assisted nature in her extremity.

Sulphate of quinine, while it is still prescribed by the routinist in typhoid fever, is eschewed by the more thoughtful men in the profession. Given day after day, to reduce a temperature which comes back day after day until the disease has run its course, was indeed very silly practice, to say nothing of its deleterious effect on the digestive and nervous systems.

"The United States Dispensatory" contains eighteen hundred closely written pages, giving the virtues of innumerable drugs. Yet alcohol and opium are of more value than all the others combined. Opium has assuaged more pain, soothed more sorrows, and saved more lives than all the remedies in the materia medica. Good doctors father no prescriptions, no specifics.

While Ringer is quoted as a believer in specific medication, while his book goes through semi-annual editions, his most vaunted remedies are for functional disorders. A good physician's highest hopes are realized when he has by opium assuaged pain, and by alcohol kept the heart wagging in the decline of some violent malady.

If we have been nature's adjunct in her extremity, we have filled our mission.

Alcohol, though slandered and vilified by fanatics, has saved millions from an untimely end. There seems to be some inexplicable affinity between alcohol and the human system. The higher the civilization the more apparent the affinity. Noah, who built the mammoth ship that saved the world, felt its soothing influence; while Solomon, the wisest of mankind, like Mohammed, interdicting wine, fell the victim of a more ravishing vice.

Noah's first thought, when his boat landed, was wine. He planted his vineyard before his corn or tobacco. The Bible says, "Give wine to him who is of sad heart, and strong drink to him who is ready to perish." But as this is not a dissertation on prohibition, æsthetics, psychology, or divinity, I will not pursue this thought further.

A doctor's faith in physic is the measure of his intellect. It is always in inverse proportion. Confidence in God and nature points to large comprehension.

When we look upon the countless millions who have lived their allotted time undoctored and undrugged, our faith in physic weakens. With all our knowledge, all our skill, we give out at threescore and ten. The divine appointment of death robs us of Utopian hope in drugs. Impossibility of proof of demonstration is at the bottom of endless controversy in medicine and divinity. We all agree about the multiplication-table. Truth is mightier than lore—than authority.

The strife between nature and art in the cure of disease has resulted in a victory for the former. Nature, unadvertised, has won a thousand trophies to one of art, whose seas of ink have been drained to prove one cure.

G. M. DEWEY, M.D.

KEYTESVILLE, Mo., August 1, 1886.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 8 to August 14, 1886.

STERNBERG, GEORGE M., Major and Surgeon. Granted leave of absence for fifteen days. S. O. 186, A. G. O., August 12, 1886.

WOLVERTON, WILLIAM D., Major and Surgeon. Granted one month's leave of absence, to commence on or about August 15, 1886. S. O. 104, Division of the Atlantic, August 7, 1886.

LORING, LEONARD Y., Captain and Assistant Surgeon. Granted leave of absence for one month, on Surgeon's certificate of disability, with permission to apply for an extension of two months. S. O. 59, Division of the Pacific, August 2, 1886.

ADAIR, GEORGE W., Captain and Assistant Surgeon. Ordered for duty as post surgeon at Fort Brady, Mich. S. O. 103, Division of the Atlantic, August 6, 1886.

GANDY, CHARLES M., First Lieutenant and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 103, Division of the Atlantic, August 6, 1886.

MERRILL, JAMES C., Captain and Assistant Surgeon. Assigned to duty as post surgeon at Fort Klamath, Ore. S. O. 130, Department of Colorado, July 30, 1886.

BENHAM, ROBERT B., Captain and Assistant Surgeon. Relieved from temporary duty at Fort Omaha, Neb., and ordered to Fort Bridger, Wyo. S. O. 97, Department of the Platte, August 5, 1886.

HOPKINS, W. E., First Lieutenant and Assistant Surgeon. Ordered from Fort Lowell, Arizona Terr., to Angel Island, Cal., for duty as post surgeon. S. O. 61, Division of the Pacific, August 6, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ended August 14, 1886.

WALTON, THOMAS C., Surgeon. To remain on present duty until September 1, 1887.

WHITE, C. H., Surgeon. To remain on present duty until August 21, 1887.

RUSH, C. W., Passed Assistant Surgeon. Authorized to delay ten days, under orders to Sitka, Alaska.

LUMSDEN, G. P., Passed Assistant Surgeon. Ordered to Hospital, Mare Island, Cal.

The Medical Record

A Weekly Journal of Medicine and Surgery

Vol. 30, No. 9 NEW YORK, AUGUST 28, 1886 Whole No. 825

Original Articles.

MANGANESE IN THE TREATMENT OF MENSTRUAL DISORDERS.[1]

BY THOMAS J. KEARNEY, M.D.,

NEW YORK.

My justification for presenting this paper is merely to relate three or four cases which, as far as they go, corroborate what has been claimed for the remedy, hoping, at the same time, to excite discussion of the subject, and thereby to elicit your experience not with manganese alone, but with the many remedies used in menstrual troubles. It was my intention, originally, to present a historical summary of what has been observed and written on the subject, but I find that this has been quite recently done in an able manner by Dr. C. E. Billington, of this city, in a paper which he read before the Section on Materia Medica and Therapeutics of the Academy of Medicine, and published in THE MEDICAL RECORD of March 6th of the present year.

Manganese is now the fashionable topic. I need not tell you that in medicine, as in society, one of the greatest motor forces is the tyrant fashion. This fact is patent at every turn one makes. You all remember that but a few years ago the most extravagant claims were made for condurango in the treatment of cancer; that eucalyptus was to supersede quinia in malaria; that the unfortunate male organ of generation (the portal through which is introduced so much of the misery that afflicts humanity) was made the prey of the surgeon's knife, with the assurance that through such procedure a revolution in the domain of neurology was to be effected. Now fashion has ceased her plague of the male sex, and is turning her attention with increased interest and renewed energy to our sisters. Behold the transformation in female anatomy and physiology that is being brought about under the new dispensation of gynecology in our day! What marvellous results, successful or otherwise, are being achieved! Some are inclined to think that ovarian surgery may be carried too far; that the propagation of the race may be seriously curtailed, if not arrested, unless, indeed, the physiologist discover some other than the old-fashioned method of conception.

But condurango, eucalyptus, and circumcision have been relegated to their proper sphere in therapeutics. It may be said that manganese is now usurping the place once occupied by the remedies to which I have above alluded, and that fashion, rather than real merit, is the cause of its popularity. I cannot deny that this is, to some extent, true—herein lies one of the dangers to be avoided; yet there are certain phases in its history which go to show that it is not to be classed with merely fashionable remedies. In the first place, manganese has not suddenly sprung into prominent notice, its acceptance has been slow, and its claims have been met with intelligent scepticism; in the second place, I think anyone who has examined the clinical evidences will acknowledge that it has a decided influence on the female generative organs in a certain class of cases.

In a very careful study of all I could find written on this subject, I have failed to find that anyone claims anything extraordinary for manganese. No prophecies of a revolutionizing character are assured through its agency. The earliest recorded case of amenorrhœa cured by manganese is reported by Dr. Henry Broadbent, in the "Proceedings of the Clinical Society of London for 1868-69," vol. ii., p. 122. It was a case of three months' standing, in which manganese chlor., gr. ij., with quin. sulph., gr. j., t.i.d., was given, with the effect of producing the menstrual flow in thirty-six days. I should state that Broadbent gave the remedy for its tonic effect alone, and with no view to the establishment of the menses directly. To Ringer and Murrell, however, we are indebted for first bringing manganese forward as an agent in amenorrhœa.

The credit of the first considerable contribution, in this country, to the study of manganese is due to Martin, of Chicago. He has employed the drug not in amenorrhœa alone, but in menorrhagia and metrorrhagia as well.

My experience has not been large enough to warrant me in holding decided views, yet I feel called upon to record what few cases I have had, and to discuss some questions of a general character in relation to menstrual disorders.

I began to use manganese in October, 1883, shortly after the appearance of Martin's first article. I have prescribed it in its different forms altogether in ten cases. In seven I used the permanganate of potash, but it became necessary to discontinue it after the first dose in consequence of the great irritability of the stomach it caused. The patients, in fact, became refractory, and would no longer submit to treatment because of what they considered the poisonous effects of the drug. They almost invariably experienced vomiting, and a sense as if a knife were being driven through the upper part of the chest, while some had, in addition to these symptoms, pretty bad abdominal pains and burnings. I have kept notes of three cases in which I have had very gratifying success, and which I will relate in the order in which I treated them.

CASE I.—Mary B——, aged twenty-six, single, U. S. Is a healthy, well-developed young woman, who, with some anxiety, consulted me in October, 1883. Stated that up to two months before she had always menstruated regularly. In the last two periods she had been irregular; menstrual flow coming on a week later, scanty in amount, and color each time becoming much lighter. I ordered potass. permanganat. in capsules, each containing two grains, one to be taken night and morning. Took one that night, and found that the flow came on very profusely in bed. Took no more, because the flow was greater than she thought normal. After this she continued regular until March 14, 1886, when she called on me, complaining that she was two weeks over her time. Having assured myself that she was not pregnant, I prescribed pills containing gr. ij. manganese binoxid., with directions to take two t.i.d. Courses came on profusely on the morning of the 17th, after having taken ten pills.

CASE II.—Annie F——, aged twenty, single, U. S. Is of delicate constitution. Has been under my care for the past three months for bronchitis, with circumscribed consolidation of both apices, during which time she has been taking cod-liver oil and iron. Called for advice and treatment, October 10, 1883. For the past eighteen months or two years menses have been irregular, sometimes too late, often too early, scanty, of pale color; is unwell for three days. Her general con-

[1] Read before the New York Medical Union, June 2, 1886.

dition now is good. Ordered potass. permanganat., gr. ij., in capsules, t.i.d. Took medicine for two days. Menses came on profusely. After taking first capsule felt pain, constriction, and burning of throat. This trouble was less after taking the other doses.

March 22, 1886: Has been quite regular since last note, which is more than two years and a half ago; quantity and quality normal.

Case III.—Mrs. A. K——, widow, aged twenty-six, U. S. Has always had excellent health, and has good family history. Has had one child. Menstruated first time at twelve years and six months; habit every three weeks, lasting five days, very profuse, with some pain; noticed that since birth of her child, which was five years ago, she began to grow very stout and at the same time to become irregular; is unwell only two or three hours, quantity small, and color pale; during her period has flashes of heat, dizziness, and headache; constipated; has enormous appetite, but no dyspepsia; she leads an indolent life, remaining indoors all the time and taking no exercise. She consulted me for these troubles in January, 1884. Ordered permanganate, gr. ij., t.i.d., in a goblet of water, for two or three days before the expected period; to take physical exercise, regulation of the diet and bowels. In the middle of the night, four or five days after this, and without having taken any medicine, she began to menstruate as usual, scantily. Took gr. ij. of permanganate next day three times, when flow became very abundant, so much so that she discontinued the medicine immediately; had to use eight or nine napkins.

February 15, 1884.—Took the medicine as ordered, yesterday, but had to discontinue it because of the stomach irritability it occasioned.

February 21st.—Patient returned to-day, and says that she afterward persevered with the medicine, but that the menstrual flow did not appear at all; head feels full and dizzy, otherwise well, as she has reduced a good deal in weight from the long walks she takes every day.

April 8th.—Expects to be unwell on the 9th or 10th; headache, fulness and throbbing of temples, and feeling as if she were going to bleed at nose. Ordered potass. permanganate in pill, gr. j., made up with paraffine, after each meal.

April 19th.—Patient did not begin to take her pills until to-day. Menstruation began immediately, and continued until the 22d, during which time she took fourteen grains in all; flow profuse.

May 10th.—Began to take pills of manganese binoxid., gr. ij., t.i.d., on the 8th inst.; became unwell that night, and still continues so. All disagreeable symptoms have disappeared.

September 23d (four months afterward).—Has been regular since last note; health excellent.

The subject of Case I. related to me the case of a young woman, with whom she worked, and to whom she gave one of the capsules of permanganate. This young woman had then (June, 1884) not menstruated for two months, and had been irregular for a year and a half. To use my informant's language, the medicine threw the patient into spasms and the menstrual flow came on in about half an hour. She complained also of distress at superior part of the sternum.

Certain reflections have been prompted by a consideration of these cases. In Case I., and in that of the girl to whom she gave the capsule, the menses came on after having taken but gr. ij. of the permanganate. No doubt you will ask yourselves, as I often have, was the menstrual flow produced by the remedy? I am inclined to think it was. Dr. Martin [1] and Dr. Billington [2] each relate a case in which the same result followed after small quantities of the drug—in the case of the former after gr. viij., and of the latter after six in twenty-four hours. Though these quantities are larger than mine, yet they must be considered small.

[1] Medical Record, September [illegible]
[2] Ibid., March [illegible], 1884.

Again, Case I. was not anæmic; she was well in all other respects and presented the appearance of perfect health. Whether or not the case at the time of the first treatment, in 1883 (on account of the small quantity taken), illustrates the efficacy of the pot. permanganate, I think the second treatment, in 1886, shows a result due to manganes. binoxid. The condition of Case II., though suffering to some extent from anæmia, had been much improved under iron and cod-liver oil. The reason I am particular to mention the presence or absence of anæmia is, because I am inclined to abstain from using remedies to promote menstruation when the anæmic state exists.

Case III. presented no signs of anæmia, though one would be led to think, from her habits, that she could be in no other condition. In fact, I considered her plethoric. This case corroborates Martin's experience with the drug in plethora, and also shows the necessity of persevering under what were, to me, discouraging circumstances, re-establishment of the menstrual molimen not having been effected until after five months of treatment.

In looking through the not very extensive literature of this subject, I noticed that with one or two exceptions the writers treat of the use of the remedy in amenorrhœa alone. Martin was the first to use it in menorrhagia and metrorrhagia as well. In his first communication (The Medical Record, September 29, 1883), he relates the cure of two cases of the former and one of the latter. In a paper read before the Chicago Medical Society, January 5, 1885, and reported in the New York *Medical Journal* for January 24th of the same year, he reports two cases of metrorrhagia and menorrhagia cured, and four severe cases of the same in the practice of Dr. D. F. Bradley, of Chicago, which were greatly benefited by manganese, when iron, ergot, gallic acid, mineral acids, astringents, and hot-water injections failed completely. Dr. T. G. Thomas, in a letter to Dr. Billington, dated February 9, 1886, claims the same results from manganese in these conditions.

At this juncture the question as to the mode of action of manganese presents itself. Again, is there any particular form of the drug which alone is efficacious in the disorders of menstruation? The permanganate of potash is the most commonly used of all the forms, but there is abundant evidence that other combinations are effective. In Broadbent's case the chloride was used. Ringer and Murrell and Thomas have had equally good results from manganese binoxid. as from the permanganate salt, and recently Martin has found the oleate a successful remedy when applied by inunction. Dr. R. Bartholow, in the *Medical News*, November 22, 1884, discusses this question and considers that the emmenagogue properties of potass. permanganate are due to the large quantity of oxygen it contains. The oxygen, according to him, is the chief factor. I cannot believe this to be so, since other forms of manganese have been at least as nearly effective as the permanganate. Cases I. and II. that I present, in which I used the binoxide as well as the permanganate, show this. I am inclined to think, however, that less of the permanganate is required to produce an emmenagogue effect.

Martin is the only one, as far as I know, who has attempted a theory of the mode of action. He says: "From my observations I have been led to consider manganese, in any form, a direct stimulant to the uterus and its appendages. It may exert its influence by acting as a direct vaso-motor nerve-stimulant to the vascular system of the parts, and in consequence of the improved circulation directly increase the tone and nutrition of the organs, or it may exert its whole force through stimulation of the sexual nerve-ganglia, or even, possibly, of the sexual *nerve-centres*, thereby bringing the organs to their normal state of action. At any rate, its action is prompt and direct. In bringing the uterus and appendages to a normal of menstrual tonicity, when lack of tone

is dependent on some previous depression of nutrition, manganese has certainly no equal." If I properly understand what is here meant, manganese should be placed in the category of those remedies called excito-motor, having the power to increase arterial tension, and with special action on the uterus.

It would resemble ergot, then, very closely in its action. Clinically, this seems so, since it is followed by equally good results in the opposite conditions, amenorrhœa and menorrhagia. It is not placed among the excito-motors by therapeutists however. Bartholow says that in small doses it diminishes the pulse-rate, lowers the action of the heart, and lessens blood-pressure. Heretofore it was always considered to be allied to such drugs as iron, zinc, nickel, etc., which tend to promote constructive metamorphosis, remedies decidedly slow in their action. As a regulator of the menses, it may be that a new property has been discovered in manganese. Further observations, however, are necessary before we are warranted in formulating a plausible theory as to its mode of action.

In speaking of the therapeutic action of this drug we are necessarily led to a consideration of the causes underlying the disorders of menstruation, and are admonished that the greatest care and intelligence should be exercised in selecting the cases in which remedies of this kind are to be used. I think you will agree with me that this is not always done; on the contrary, there are no complaints in which more unintelligent prescribing is prevalent than in the class of cases here referred to. There is no doubt that this is due to the fact that amenorrhœa and its opposite conditions are looked upon as diseases instead of mere symptoms. They are never primary in their origin, but are always dependent on unhealthy constitutional conditions or local organic disorders, either alone or combined. Trousseau says: "As long as these general troubles exist, we vainly try to recall the menses with drugs; the first condition of all is to re-establish equilibrium, and then the special excitant of the uterus becomes an important weight in the scale."

No doubt you are as much impressed with this statement as I, and may consider it unnecessary to quote it; but my memory is not so poor that I can forget how short a time ago it is since I came to recognize and understand its truth. The great danger in becoming too enthusiastic about new remedies is that a habit of superficial and one-sided observation is bred in us—therapeutics being advanced at the expense of pathology. Manganese will no doubt be found a very efficient remedy, but we must not fall into the error of believing it to be a specific. This indeed it is not, and few if any will be found to make such claim for it. I believe it is a drug which simply promotes constructive metamorphosis, acting like iron and its congeners, by supplying a natural and therefore necessary constituent to the blood. In addition to this it has, no doubt, some special action on the uterus, for how can we otherwise explain its effects in menorrhagia and metrorrhagia, where the promptness of its action is in marked contrast to the necessarily slow operation of general nerve and blood tonics?

In speaking of the treatment of amenorrhœa I want to particularly call your attention to some errors into which many have fallen. It is pretty generally believed, I think, that some peculiarly mysterious and deleterious influence is caused immediately and necessarily from the discontinuance of the menstrual flow. And again, it is thought by not a few that because the remedies used produce a flow of blood from the uterus, that menstruation is therefore established. To quote Trousseau again, where he speaks of the treatment of amenorrhœa: "A great many morbid states hold the function in check and simulate (so to speak) the part of pregnancy. How often a careless physician stumbles against such a contradiction. One of two things happens: either the emmenagogue succeeds or the morbid obstacle resists its action. Suppose the emmenagogue carries the day; it has forced the contradiction. Do you think your conquest legitimate? No. You have produced a uterine hemorrhage, but you have not re-established the menses."

. . . . . .

"The emmenagogue stimulants may cause fluxion of the womb, but they either cause uterine hemorrhages, which are not the menses, or if they restore the function legitimately, it is because the diathesis of the function (so to speak) pre-existed, and was only awaiting an auxiliary stimulus."

It is pretty generally believed now, that normal menstruation is always accompanied by ovulation. Suppose then, a depraved state of the blood or a condition of enervation exists which of necessity interferes to the extent of arresting ovulation, of what avail will our emmenagogue remedies be while this constitutional condition lasts? In anæmia, for instance, will we not do harm when we cause a uterine hemorrhage which can have no other effect than to increase the anæmia? Among the cases reported as having been successfully treated with manganese, I noticed many in which anæmia was considered the underlying cause. I say successfully treated, because they were so reported; but I am not altogether sure that the treatment was always successful. Very often there was nothing in the reports to show that the cases were observed for any time beyond that in which the menstrual flow was initiated. How are we to know, then, that the remedy caused anything but a temporary uterine hemorrhage, which, if an anæmic state obtained, rendered the patient's condition worse than before? In such a condition of things we are forcibly reminded of the good old times when resort to the lancet was so common in fevers. Instead of pyrexia being reduced by the venesection it was increased by the loss of blood; this cause of fever, however, being little understood or wholly ignored, phlebotomy was again utilized, to the destruction of the patient.

According to Ringer and Murrell, manganese is contra-indicated in cases of acute congestion and in general conditions of sthenic reaction. They also assert that abortion is not liable to result from ordinary doses, should pregnancy be overlooked in any case. For my own part, such has been the powerful effect of the permanganate salt in particular, in my hands, that I would hesitate long before giving the drug unless perfectly sure of the absence of this condition.

The Prevalence of Infanticide in China.—There is a missionary society in existence, with its headquarters in France, the object of which is the rescue of Chinese infants abandoned to die by their parents. Colonel Cheng-Ki-Tong, in a recent work, "Les Chinois Peints par Eux-mêmes," denied that such a custom prevailed, and held up to ridicule the children belonging to this society, who, he said, were beguiled into giving their pennies for the rescue of infants who did not need rescue. Dr. D. J. Macgowan, however, in a paper in the *China Review*, shows that this custom is prevalent in many parts of that country, to such an extent, indeed, that numerous asylums have been erected by charitable individuals among the Chinese themselves for the reception and care of these neglected infants. Female children are the only ones drowned, boys being needed to conduct ancestral worship. The parents are usually very willing for a little cash to sell their girls instead of destroying them.

A Large Fibrolipoma.—Dr. W. Stankiewicz reports the case of a patient who had a tumor in the lumbar region, which had been growing for fourteen years and was of such a size that it hung down to the knees. Its base was forty-four inches in circumference. It was removed by operation, and weighed, after extirpation, forty pounds. —*Centralblatt für Chirurgie*, May 15, 1886.

THE DETAILS OF THE OPERATION FOR REMOVAL OF MAMMARY CANCER.

By ROBERT T. MORRIS, M.D.,

NEW YORK.

In a standard work on surgery, published as late as 1882, the article on amputation of the breast contains the following information: "The integuments should be brought together and maintained *in situ* by plaster or some other means, according to the inclination of the surgeon. Compresses of lint should be adjusted along the edges of the wound to maintain the flaps and subjacent tissues in close apposition, but openings must be left at either extremity of the wound for the escape of discharges." The reviser of the article adds a word in reference to extensive removal of malignant neoplasms, and says that "healing by first intention under these conditions is, of course, often out of the question, and such wounds heal slowly by granulation." To find information of this character in a modern work on surgery is certainly exasperating to the practical surgeon of to-day; and perhaps a concise description of the operation, and of a sort of wound treatment which belongs to this part of our century, will be of value to ambitious operators who have nothing but standard works to depend upon for instruction.

The greater number of surgeons will prefer, I suppose, to have a description which figures a case in private practice at the house of the patient.

For an operating-table the kitchen-table will answer very well. It is placed in a good light, covered with a quilt and a sheet of rubber, and is tipped a little to one side in order to allow irrigating fluids and blood to run off into a basin placed below.

A smaller table is moved to a point conveniently near, and is furnished with the following instruments and materials:

First: A roast-beef platter filled with 1 to 30 carbolic-acid solution, and holding a pair of vulsellum forceps for lifting the breast; half a dozen retractors of different shapes and sizes for managing slippery tissues; a pair of large and a pair of small curved scissors for trimming away fascia, etc.; a pair of straight scissors for cutting dressings, and a couple of scalpels. A pair of mouse-tooth forceps for lifting small portions of diseased tissue will be found very handy.

Second: A quart bowl filled with 1 to 30 carbolic-acid solution, and holding eight or ten artery forceps.

Third: A saucer partially filled with alcohol, and containing four metres of No. 8 catgut, and one of No. 5, prepared according to Kocher's method;[1] a metre of No. 7 chromic catgut; a large needle, and a large absorbable bone drainage-tube.

Fourth: A saucer of 1 to 30 carbolic-acid solution containing two strips of sheet lead, each of which is about four inches long and an inch wide, and perforated at intervals of half an inch with an awl; several half-split BB shot, and a few strands of silkworm-gut.

Fifth: A bottle of Lister's protective oiled silk in 1 to 30 carbolic-acid solution.

Sixth: A bottle of iodoform.

Seventh: A razor and nail-brush, and a cake of soap.

Somewhere near the table hangs a common fountain syringe, containing two or three quarts of warm 1 to 2,000 bichloride of mercury solution.

A wash-bowl of 1 to 1,000 bichloride of mercury solution contains four towels and two sponges.

The etherized patient is now brought in and placed upon the table. The diseased breast, the axilla of that side, and the skin for several inches about are soaped, shaved clean, and then scrubbed with the nail-brush and washed with 1 to 1,000 bichloride solution.

The operator and his assistants wash their hands in soap-suds and then in 1 to 1,000 bichloride solution, and they do it thoroughly, too, if they appreciate the fact that a life has been placed at their disposal.

One of the assistants takes the straight scissors from the dish of 1 to 30 carbolic-acid solution, cuts one-fourth of a yard of bichloride gauze from the roll in the clean tin-can, musses the gauze into a fluffy handful, and puts it on a towel. He then pulls out of its cover half a pound of bichloride cotton, taking care that it does not hit his clothes, and lays it on the towel with the gauze. The towel is rolled up about its contents and stowed away until after the operation.

A towel is taken out of the bowl of 1 to 1,000 bichloride solution, wrung dry, and laid across the patient's chest just below the breast (the patient lying on her side). A second prepared towel covers the shoulder and arm, while the third towel is spread on the rubber sheet between the patient and the surgeon, in such a way that instruments, sponges, catgut, and hands will touch no unprepared thing.

One assistant holds the arm of the affected side above the patient's head, and the arm is to be kept in this position until the operation is finished. The surgeon having determined the outlines of the cancerous mass in the breast, carries an incision through the skin around it, and so far away from its margins that healthy tissues only are cut into. The distance from the diseased part at which the surgeon must cut will vary very much with the case, and this point is to be learned by experience only. If a cancerous tumor could be colored deep blue, we should probably find the deep-blue color running through the mass to the axillary lymphatics, and thence to the deep lymphatics of the neck. The muscles and fascia in the vicinity would be colored less and less deeply, until the hue gradually faded out and became lost in the tissues at several centimetres' distance. To eradicate this great nest of microbes, and prevent their heaping up morbid accumulations of cells in the near future, a pretty extensive operation is always required. It will not do to follow the lines of incision which are usually given in the text-books, and the operation must be done without much regard for the beauty of the flaps or the graceful curve of the line of incision. It is well, however, to make the first cut on the lower side of the tumor, so that blood from the higher incision will not obscure the field. A few rapidly made strokes with the scalpel now divide the subcutaneous fatty tissue, and then a pause is made in order to pick up and ligate bleeding vessels with No. 8 catgut. The breast is seized with vulsellum forceps by an assistant, and traction is made while the surgeon divides the fascia of the great pectoral muscle, and shells out the cancerous mass with its surrounding layers of fat. The fountain syringe is to be used at frequent intervals, until the whole operation has been completed. And the bichloride solution is thrown not only over the surface of the wound, but also over the skin in the vicinity.

The next step in the operation is to clear out the axillary lymphatic glands and vessels and the loose axillary fat and connective tissue. It makes little difference whether these tissues are badly diseased, or whether they show no sign of being implicated, they are to be cleanly removed at any rate. The incision for giving free entrance into the axillary region should extend from the wound already made, up along the inferior margin of the great pectoral muscle as far as to its point of insertion into the humerus. It is a pretty good plan to dissect directly down to the axillary vein when this has been done, because the vein is a first-class landmark and there will be less danger of cutting or tearing its coats. If this enormous vein should be opened accidentally, it must be closed by ligation of the portion about the wound, and not by ligation of the vessel in its whole circumference. It would seem as though the cephalic vein ought to be able to carry the return flow of blood from the arm, but a sufficient number of cases of gangrene of the arm following injury to the axillary vein have given

[1] The unprepared catgut is put into oil of juniper for forty-eight hours, and is then transferred to a bottle of turpentine and alcohol, in which it remains until wanted for use.

serious testimony, and we must keep a sharp eye on that vessel.

Before removing tissues from the axilla, it is best to hunt out the internal cutaneous, intercosto-humeral, and three thoracic nerves, and to free them from surrounding tissues. If they are evidently involved in the disease they had better be removed, but the patient will want them if they are found to be worth keeping. There is not often danger of cutting the other important nerves at the bottom of the wound accidentally.

The axillary glands and fat, and the fascia which holds the lymphatic vessels, are removed thoroughly. In one of my cases, in which the glands were not very extensively involved, the little lymphatic vessels were hard and knotty, and a branch an inch or so in length could be held out horizontally by one end, just like a tiny twig of samphire.

The lymphatics which extend up to the clavicle can ordinarily be removed without the necessity of dividing the pectoral muscles transversely, but sometimes this will have to be done when the fascia looks suspicious.

While removing the lymphatics from under the clavicle, the operator should remember that a gland lies hidden, like a little mouse, between the opposed margins of the deltoid and major pectoral muscles, and that it will very likely creep out and go to eating again as soon as the surgeon has passed. An incision an inch in length, through the skin over the clavicle, will usually give room for removing this gland. The cervical glands and vessels which we meet on our way to the thoracic duct, or to the right lymphatic duct, can be brought out through the same opening. The last step in the operation will be to remove the fascia from the anterior surface of the major pectoral muscle, and from over the ribs and serrated muscle if it is necessary to do so. If muscular tissue is anywhere involved, it must come out, and the incision must go a long way from the diseased part into healthy muscle. Hemorrhage is stopped at every point by ligating the cut vessels with No. 8 catgut.

In closing the wound, the well which has been made in the axilla will disappear if the arm be let half way down. The air being pressed out of the hole, atmospheric pressure will keep the tissues in apposition in that region afterward.

One or two or three principal interrupted sutures of chromic catgut or of silkworm-gut are now inserted through the skin flaps. If the flaps are not heavy, the chromic gut can be tied in the ordinary way. If the flaps are going to make considerable tension on the sutures, the ends of the gut instead of being tied are passed through the holes in the strips of lead which have been waiting in the carbolic-acid solution; and then the split shot are pinched on to the gut ends, so that the strips of lead will take most of the tension from the sutures which are to close the wound.

Silkworm-gut is to be used in the place of the chromic gut only when there is danger that fourteen days' time will not give sufficiently long support for the flaps. Chromic catgut will not last much longer than two weeks, but silkworm-gut does not become absorbed at all.

The margins of the flaps are next united as far as possible with interrupted sutures of large catgut, and then a continuous suture of the smallest catgut makes the neatest possible approximation of the edges. If the margins of the wound can be everywhere approximated, so much the better; but this point is not to be considered during the performance of the operation, because a large exposed space left to heal by granulation is much preferable to a prettily closed wound which covers cancer-impregnated tissues. Primary union will occur in both of the wounds; and the granulating patch which is left in the one case can easily be covered with skin grafts or with a piece of skin transplanted from the arm, if it is too large to heal without aid. After all of the sutures have been inserted and an opening for the drainage-tube has been made, the bone-tube is put in in such a way that the axilla will be well drained. At the time when the tube is inserted the patient's arm must be held rather near her side, in order to relax the muscular walls of the axilla. If this is not done the air will probably rush into the wound cavity again, and then the surgeon has to fuss with the wound for several minutes in order to get the air out.

The temptation to give a final flushing with bichloride solution through the open-mouthed, inviting-looking drainage-tube is sometimes hard to control; and the feeling is somewhat akin to the one which the operator has when he longs to give the wound a final wipe with the cleaning-up towel. It is not safe to flush the wound through the drainage-tube, because a good deal of the bichloride solution may remain back in the wound. The reason why bichloride of mercury is an unpopular antiseptic in some sections of the country is because a little gumption is required in order to use it properly.

A harelip pin stuck through one edge of the emerging end of the drainage-tube will sometimes be required in order to keep it from slipping in beneath the skin. I made this suggestion at an operation not long ago, and one of the bystanders took a pin out of his pocket-case, swashed it around in the carbolic-acid solution a couple of times, and then handed it to me for use. Was that pin ready for use? Not at all! it needed a bath in pure carbolic acid for several minutes first.

After the drainage-tube and sutures are satisfactorily arranged, some iodoform should be rubbed all over the skin in the region of the wound, and any exposed tissues should be well sprinkled with it.

A piece of Lister protective, just large enough to cover the sutures and the exposed tissues, is next taken out of its bottle of antiseptic solution and spread evenly in place, a hole being torn in it opposite the drainage-tube opening.

The bichloride gauze is taken out of the towel and placed over and around the protective; and the bichloride cotton covers everything beneath it. A strip of muslin eighteen inches wide, with a hole for the forearm of the wounded side, is now passed around the patient's chest and pinned snugly in place, so that the dressings will not slip and so that the arm is kept perfectly at rest. No particular after-treatment will be necessary until two or three weeks have passed; and if no space has been left to heal by granulation, the wound will be entirely well at the end of that time.

The patient can get out of bed as soon as she pleases after forty-eight hours have passed, and I seldom have to restrict the diet after that period of time.

The dressings are not to be changed until two or three weeks have passed, but if serum runs through the cotton, the bedclothes must be turned down so that drying can go on quickly.

The most difficult thing which the surgeon has to do in an operation of the sort above described is to give close attention to untrained assistants, in order to be sure that they violate no antiseptic rule. Without intending to do so, an assistant who is absorbed in the operation may lay a sponge or an instrument on the bare table or on a chair.

When, at the end of two or three weeks, the dressings are removed, it will be found that primary union has occurred, and that there is no pus in the dressings. I believe that there is almost never excuse for suppuration on the ground that the patient is too old or too young, or too sick or too robust, or too fat or too lean, or too rich or too poor, or too anything else that one can think of.

To suppose that suppuration, or septicæmia, or pyæmia, or erysipelas, or tetanus are liable to result from a large wound is nonsense, unless the operator happen to belong to one of the following groups:

1. Men who became successful surgeons in earlier times with old methods, but who are now too far advanced in years to take up the newer and better methods of to-day, and who delude themselves with the notion

that the details of an antiseptic operation resemble the "walking and the talking of the prestidigitator."

2. Men who have had no opportunity to learn scientific antiseptic methods of work.

3. Men who cannot learn scientific antiseptic methods of work.

As regards the probability of recurrence of the disease after removal of mammary cancer, it is extremely difficult to make a prognosis in any given case. Statistics are really worthless on this point, because authors are not in the habit of stating the exact extent to which their operations were carried; and the painstaking sort of work which we now do is of quite a recent date. If it is possible to remove tuberculous tissues completely in caries of the knee-joint, it seems as though we ought to be able to remove cancerous tissue completely in some cases of this disease.

We know that in the majority of instances the blood is infected, and that the disease will break out again at an early date.

I find that physicians living at a distance from the great medical centres are, as a rule, opposed to operation in cases of cancer. They say that the patient must endure the suffering of an operation without gaining very much by it. Here there is a great field for reform work, and so soon as physicians and patients awake to a full appreciation of the advantages given by a strictly antiseptic operation they will not hesitate about a decision in favor of the removal of cancerous neoplasms. The operation, when done according to methods which are fully up to the times, and on operable cases, will cause the patients no actual suffering; and the intervals of freedom from the disease which are thus given will be delightful periods for the poor victims.

I have no patients who are more grateful than my cancer patients, although to all of them I have said, "your disease will undoubtedly return."

SOME IMPROVED FORMS OF BURNERS FOR THE GALVANO-CAUSTIC TREATMENT OF NASAL AND POST-NASAL HYPERTROPHIES.

By FRANK B. EATON, M.D.,

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY IN THE MEDICAL DEPARTMENT OF WILLAMETTE UNIVERSITY, SALEM, ORE.

If we compare the surgical methods of treatment of nasal and post-nasal diseases in vogue in Europe with those employed by our own surgeons, we are struck with the fact that the latter are, in spite of their advanced position in other fields, rather in the rear in this, except, perhaps, in respect to one weapon—the cold snare.

A reference to the earlier contributions of such progressive workers as Baginsky,[1] Löwenberg,[2] Voltolini,[3] and Thudichum,[4] will show that another method of treatment—*the galvano-cautery*—has long been the more favored one in England and on the Continent. Thudichum, indeed (*loc. cit.*), employed the galvano-caustic snare for the removal of nasal polypi as long ago as 1864, and gradually the electrode has replaced the various cutting and tearing instruments among the majority of operators in the majority of cases. Issue may be taken with the above statement as to the backwardness of our surgeons in the treatment of nasal diseases. Let me not be misunderstood. In our great medical centres are surgeons as competent, advanced, and progressive in the treatment of nasal diseases as any abroad; but they have yet to produce treatises as comprehensive as that of Mackenzie, or manuals as practical as that of Woakes;[5] hence the average of information on these subjects among our surgeons at large, who, as a rule, read first the works and follow the methods of their countrymen, is less than that of foreign surgeons. In no way can I so well substantiate these assertions as by referring the reader to a posthumous paper of R. Schalle, of Hamburg, published in the "Archives of Otology" in 1882.[1] In this most practical and valuable series of observations were anticipated, by its author, before 1880, many of the surgical procedures in the nasal cavities, and especially those by galvano-cautery, with which the majority of our surgeons are only just becoming familiar. No doubt a prime factor in retarding the general employment of the galvano-cautery in this country, for the treatment of nasal troubles, has been that most ingenious and now familiar instrument—Jarvis' snare. In the skilled hands of its inventor it will accomplish, no doubt, all that can be accomplished by any form of cold snare; but I appeal to the experience of the majority of the surgeons who have used it whether it has not in the end disappointed their earlier expectations, particularly in cases of the smaller and sessile posterior hypertrophies of the turbinated bones. These the snare is "clever" enough to engage; but, alas! just when we are sure that the loop has begun to cut through the growth, it provokingly glides over the surface, slips off, and the wearied patient must submit to a renewed attempt. This not infrequently happens, too, with the larger hypertrophies.

I have succeeded in introducing needles through posterior hypertrophies, and thus snaring them off, by means of an ingenious little needle-director which Dr. Jarvis showed me, invented by himself, and which he kindly permitted me to have duplicated and put upon W. F. Ford's catalogue. Dr. Jarvis informed me, however, that from constant practice he is sufficiently expert to introduce needles through posterior hypertrophies unaided by any special instrument. Those who have attempted to transfix such growths will nevertheless, I think, agree with me that, even aided by his needle-director, this is generally extremely difficult to accomplish, especially in cases of small hypertrophies, and it is almost impossible to transfix any posterior hypertrophy at its base. Again, the removal of anterior hypertrophies by the snare has always been extremely painful, nor does cocaine avail to prevent it, and in this tedious mode of operation the suffering entailed is often bitterly referred to by the patient. It is not without reason, then, that the galvano-cautery has been preferred before the snare in many cases by surgeons long experienced in the treatment of diseases of the nasal cavities. There are, of course, cases in which the snare would be preferred, as, for instance, in marked hypertrophy of the pharyngeal tonsil and in most cases of polypi. But even in these cases the cautery finds its place, and should follow the snare in the after-treatment. It is clear that in some cases cutting-forceps, such as Dr. Löwenberg's post-nasal forceps, have advantages over all other instruments; but I maintain, in favor of the galvano-cautery, its superiority in respect to adaptability to the greatest variety of circumstances, as, for example, to adults or children, to use anteriorly or by way of the mouth, etc.

As to the comparative value of chemical cauterization, the testimony against this last method is so universally unfavorable that I need not consider it here. With all these objections in view to other methods, what proportion of our surgeons commonly make use of the galvano-cautery in diseases of the nares? Comparatively few; and it is the purpose of this article to account for this, and to describe a form of battery and improved burners which are within the reach of all surgeons, and useful in the hands of those of average skill.

In the first place, until lately the high price of the cautery batteries in the market, the difficulty of managing and keeping them in order, and the fact that they were unnecessarily large and powerful for use in nasal

[1] "On Acute and Chronic Inflammatory Diseases of the Nose, and some of their Methods of Treatment, a posthumous paper, by R. Schalle, Hamburg, Archives of Otology, vol. xi., p. 118.

diseases, has deterred many surgeons from purchasing them.

Many physicians possess but a limited knowledge of electric science; hence they imagine that it requires a large, powerful, and expensive battery to furnish a current sufficient to heat the nasal electrodes. This is an error. The size and number of plates are in proportion to the amount of platinum that must be rendered incandescent. A large electrode-écraseur, such as used, for instance, for amputating the cervix uteri, requires a powerful current, such as furnished by a number of plates of considerable size, and a correspondingly large amount of exciting fluid, these involving an expensive apparatus.

But the burners used in the nares are practically very small knives, or small wire snares, and a current sufficient to render them incandescent is readily derived from one large cell of two elements arranged for quantity. The battery which above all is suited for this purpose, as to convenience, efficiency, and economy, is that devised by Dr. Carl Seiler, of Philadelphia.[1] The one shown in the cut is that especially designed for use with nasal burners. It is thus described by Dr. Seiler:[2]

"This battery consists of a series of carbon and zinc plates connected for quantity, . . . mounted on a plate which is fastened near the top of the box, so that they hang from the interior of the box. Immediately beneath the plates is a hard-rubber cell containing the exciting fluid, mounted upon a platform which can be raised or lowered by means of a treadle projecting from the box. This treadle is jointed, so that by folding it up it can be placed inside of the box out of view and harm's way. When it is depressed, the platform with the cell rises, and the system of plates is immersed in the exciting fluid, whereby the current is established. The height to which the cell is raised determines the amount of current, and consequently the amount of heat in the platinum loop. . . . As the treadle is actuated by the foot of the operator,[3] it will be seen that he can control the amount of current during the operation without the aid of his hands or of an assistant, as is necessary in the case of the ordinary galvano-cautery batteries, and can regulate the temperature of the knife to a nicety. The rubber cell being large, contains a large amount of fluid, and as the plates are entirely out of the fluid when the platform is lowered, the liquid is not readily exhausted, so that the necessity of refilling the cell with fresh fluid does not occur very often; a point the advantage of which will be apparent to everyone who has ever used a battery with small cups which require refilling after each operation."

It would be difficult to say too much in praise of this battery, and of its advantages to the surgeon.

It cannot, however, be said that Dr. Seiler has been equally happy with the handle and burners which he has devised to accompany his battery;[4] nor are those of Dr. Shurley[5] free from serious imperfections. Their handles, in common with all those furnished by our instrument-makers, are far too large and clumsy for delicate manipulation. The nasal mucous membrane being one of the most sensitive of the body, every untoward movement of the surgeon's hand while directing instruments in the anterior nares inflicts considerable pain, and it is needless to state to those who have used the above handles (Dr. Seiler's is five and three-fourths inches long and weighs two and one-fourth ounces) that not only is unintentional pain often inflicted, but anything approaching delicate manipulation or complete control of the electrode is impossible; for these handles must, from their size and weight, be grasped; being too large and heavy to be lightly held by the fingers. As for the nasal electrodes or burners introduced by the above well-known surgeons, there is one singular defect common to all, and that is that their greater diameter (transverse), including that of the platinum knife, when fixed in the handle, is horizontal instead of being, as it should, vertical. The transverse diameter of the anterior nares being almost obliterated in many cases of hypertrophic catarrh, the disadvantage of this is obvious.

Another defect is that most of the burners employed in the anterior nares to destroy hypertrophied tissue of the turbinated bones are used as *knives*, to make incisions. Now the object of all cauterizations of these parts is to form *broad* cicatrices, which is to be accomplished rather by *searing* than by incising; and, besides, a seared wound does not bleed as does an incised one. Again, none of the electrodes now made, to my knowledge, are suited to destroy posterior hypertrophies of the turbinated bones, while those devised by D. Lincoln[1] for use in the post-nasal space are too long and bulky, and involve the use of a large handle.

Dr. Shurley's burner, for use in the same region, has not, I think, a sufficient incandescent surface, though it is very useful. Many of the electrodes now in use are covered with asbestos, vulcanized fibre, or other non-conducting material, which interferes with attempts to bend them to any great extent. The object of such coverings is to insulate the wires of the electrodes, and to protect the parts not to be burned. A suitable battery renders such coverings entirely unnecessary, as the platinum is quickly rendered incandescent, and the cauterization is accomplished before the copper wires leading to the platinum have time to become heated. Besides, these coverings increase the diameter of the electrode and obstruct the operator's view.

In the electrodes I have devised and tested in a great variety of pathological conditions of the nasal cavities, I have endeavored to do away, one by one, with the objectionable features above enumerated, and to adapt them to reach those parts of the nares hitherto entirely, or only with difficulty, accessible to the cautery. First of all, I discarded the large and clumsy handle and the circuit-closer, substituting for the former a small, light handle in one piece with the electrode, and for the latter the closing of the circuit by the foot, after the manner of Dr. Seiler, using for this purpose a battery of my own construction, though I prefer the one described above of Dr. Seiler. Each electrode, as seen in the cuts, has its own handle, measuring one and three-fourth inch in length, permitting it to be held lightly between the thumb and one, two, or three fingers. Their average weight is but one drachm and a half. The conducting-cords are attached directly to the electrode. A set of these burners, as devised by me, comprises eight pieces, to which I have given appropriate names.

The *lateral burner* (that for the right naris is shown in Fig. 3–A), perhaps the most generally useful of all, is jointly the device of Dr. R. G. Rex (formerly of this city, now of San Francisco) and myself. Notwithstanding its resemblance to that introduced by Löwenberg,[2] it materially differs from his, and was made and used by me before either Dr. Rex or myself knew of the latter's existence. The essential point of difference is the position of the platinum relative to the vertical diameter of the electrode. In Löwenberg's burner, in order to bring the platinum in contact with the tissue to be burned, it is necessary to turn the instrument upon its axis, and thus the greater diameter becomes parallel to the horizontal diameter of the naris, which, as pointed out above, is a practical disadvantage. The great advantage of my lateral burner is that, owing to the platinum arising from the distal end of the lower copper wire in a gradual

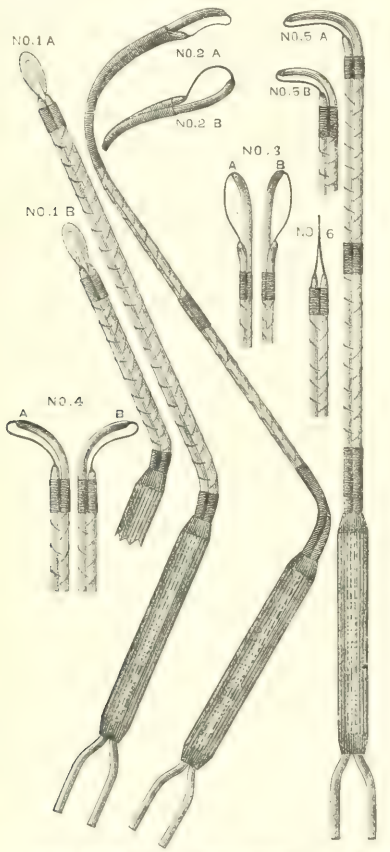
curve, the plane of which is at a right angle with the vertical diameter of the electrode, and the diameter of the copper wires being only one and one-fourth millimetre, it is possible to destroy with it erectile or other hypertrophic tissue that is in actual contact with the septum or nasal floor opposite without burning the latter. This advantage I have found greatest in cases of hypertrophy of the tissue of the middle turbinated bone, which is often in contact with the septum.



Dr. F. E. Eaton's Naso-Pharyngeal Cautery Electrodes: 1–A, long spatula-burner, for hypertrophy of turbinated bones; 1–B, short spatula-burner, for anterior hypertrophy of turbinated bones; 2–A, lateral S burner, for growths on post-nasal space; 2–B, S burner, for growths on post-nasal roof; 3–N, lateral burner for right nostril, for hypertrophy of turbinated bones; 3–B, the same, for left nostril; 4–A, scythe-burner, for right nostril, for posterior hypertrophies of turbinated bones; 4–B, the same, for left nostril; 5–A, post-nasal scythe-burner, for growths in post-nasal space; 5–B, the same, of smaller size, for children; 6, pointed burner, for puncturing anterior hypertrophies.

The platinum of this and all the burners is No. 27 (English standard), which I have found to be of sufficient thickness to produce a searing effect, and to burn deeply.[1] Owing to the above-described curved shape of the platinum, it is possible, in some tolerant cases, by keeping it at a white temperature, and beginning the incision at the posterior end of the inferior turbinated bone and drawing it steadily forward, always aglow, to destroy the hypertrophied tissue upon the latter, throughout its length, in one sitting, for the curved platinum does not catch as long as it is kept glowing and steadily moving.

In Figs. 4–A, and 4–B, is shown my *scythe-burner* for the destruction of posterior hypertrophies of the *right* middle and inferior turbinated bones. A similar one, with the "scythe" turned to the right, is used in the left naris. It is not unlike the one described by Schalle,[2] who gave it its name; but the arrangement of the platinum is different, being carried on to form the end of the hook or "scythe," and being used for a different purpose. It is admirably adapted for destroying posterior hypertrophies of the turbinated bones, and with it I have successfully accomplished this, even when circumstances made it impossible to direct the burner by posterior rhinoscopy. In such cases I introduce it, scythe upward, from in front into the post-nasal space, then bring the handle to a vertical position (the scythe being at a right angle to the handle), draw the instrument forward directly in the line of the turbinated bone until the scythe hooks itself upon the hypertrophy (which, as in the case of the snare, is the only obstruction which checks its progress), and make the platinum glow. Of course it is better to direct the burner, especially in posterior hypertrophies of the middle turbinated bone, by the rhinoscope.

This burner I have also often used to produce absorption of large enchondromas of the septum, as the point of the scythe, when glowing, can be sunk deeply into the cartilaginous growth on its posterior, as well as its upper and outer surfaces. In some cases of polypi of the middle turbinated bone, which cannot be engaged in the snare, this scythe-burner can be passed behind the pedicle and the latter burned through.[2]

The *long* and *short spatula-burners* (Figs. 1–A and 1–B) differ only slightly from those generally used, as far as the shape of the platinum is concerned. They have the same general features, as to handle and proportions, with my other burners; but I have directed Mr. Flemming to bend the platinum longitudinally into a "furrow" shape. They are used to enlarge the wound made by the lateral burner, which is **V**-shaped, by passing them, when glowing, along its track. They are also useful for burning the anterior surface of the middle turbinated bone. For growths in the post-nasal space I use two forms of burners. One of these is an invention of my own, which I call the *S burner*[3] (Figs. 2–A and 2–B). The original feature of this burner, besides the handle, is the position of the platinum—a piece of curved No. 27 platinum-wire being placed upon the upper side, instead of the usual distal spatula-knife. The advantage of the wire over the knife I find to be not only that the wire is more easily brought in contact with the different parts of the roof of the pharynx, and, when glowing, passes readily through inequalities; but, being blunt, it does not catch in and lacerate the mucous membrane in its often unavoidable contact with it during its introduction, as is often the case with Dr. Seiler's electrode. It is so made as to be readily bent to any desired shape. Mr. Flemming also makes modified forms of this burner (not illustrated), with the platinum-wire turned to the right and left, after the manner of the lateral burner, which are very convenient for burning the hypertrophied salpingo-pharyngeal folds leading from the orifices of the Eustachian tubes to the fauces in many cases of postnasal catarrh.

In Figs. 5–A and 5–B, is shown Schalle's *long post-nasal scythe-burner*, to be introduced by way of the anterior nares. It is the same form of instrument described as follows by him, except that I employ copper wires of less thickness and prefer a smaller scythe for children. Schalle describes it thus:

"The latter (scythe-burners) consist of copper wires 2 mm. thick, one of which bends above in scythe form, continues transversely for 12 or 14 mm., according to circumstances, and then, being bent again, runs again in the direction of its first part; but at a distance of 2 mm. its course is continued in a platinum wire to which it is soldered, so as to return to its point of origin, where it

[1] Hemorrhage from erectile tissue is avoided by lifting the burner from the wound while incandescent, and by using cocaine beforehand.

[1] Archives of Otology, xi., p. 135.

[2] An interesting case of this kind is narrated by Schalle, Archives of Otology, vol. xi., p. 142.

[3] A term applied by German surgeons to the common double-curved post-pharyngeal electrode.

joins the second returning copper wire. When the instrument is applied behind the proliferation (pharyngeal tonsil), the platinum wire closely hugs the upper pharyngeal wall, and when rendered white-hot and drawn toward the nasal septum, it destroys the proliferation."[1] Concerning its use in the case of children, he says further: . . . "operation under digital direction is always preferable in children. In them I also introduce the scythe-burner through the nares, then bring it into its correct position by the finger of the other hand, introduced through the oral cavity, and make it glow. In using the scythe-burner, the action of which here is excellent, the point of the guiding-finger is protected from being burnt by the intervening space, so that we have the advantage of controlling the incandescent instrument by the palpating finger."[2]

In adult patients with quiet palate I prefer to use Jarvis' snare, with curved cannula from the mouth, in cases of hypertrophy of the pharyngeal tonsil where the growth is large enough to be engaged in the loop; but in sessile, small hypertrophies of this organ, I prefer, in adults, to use the above-described S burner. I have never yet experienced the disagreeable results produced by reflex irritation of the accessory nerve, following the use of burners in the post-nasal space referred to by Schalle,[3] though I have often freely burned hypertrophied tissue in all parts of this cavity; nor do I think this accident likely to follow cauterizations done under rhinoscopy, but only such blind, and I think unjustifiable, operations as performed by him, in some cases, unassisted by the mirror or palpating finger.[4] Fortunately, as is well known, the fauces are remarkably insensitive in many cases of serious post-nasal obstruction, and rhinoscopy is easy.

In conclusion, I would state that I have given due credit for all ideas and hints I have utilized in the construction of these burners. Schalle's burners, if indeed they were ever made for general use, I have never seen. The form and proportions of my burners have grown out of my own experience in treating chronic hypertrophic catarrh, most cases of which have come under my care complicated with acute and chronic catarrh of the middle ear, a form of aural disease which the moist climate of the Willamette Valley seems to render unusually common in Western Oregon.

In a future article I hope to give some useful hints upon the indications for the use of the galvano-cautery in nasal and post-nasal catarrh, complicated with aural disease, illustrated by appropriate cases.[5]

NOTE.—Since writing the above I have found it better to work with the battery placed upon the floor, instead of carrying out the plan of placing it upon a table. To obviate the weight and stiffness of the heavy conducting cord, I have directed Mr. Flemming to shorten it to thirty-five inches, and to continue it into two light cords to which the burner is attached. The dragging weight of the cord is avoided by simply supporting it by drooping it over the pipe of the condenser, or fixing by any device which may occur to the operator.

The *pointed burner* (No. 6) I devised to carry out the plan suggested by Dr. Henry Schweig (THE MEDICAL RECORD, vol. xxix., No. 26, p. 206), of puncturing anterior turbinated hypertrophies. This method I have tested and found effectual for destroying hypertrophies of the anterior third of the inferior turbinated bone. Naturally it is limited to these, as the point cannot be guided accurately farther back. The point is half an inch long, and is not represented of sufficient length in the cut.

Clinical Department.

THE EFFECT OF SEA-BATHING ON THE EAR.

DR. SEXTON'S AURAL CLINIC, NEW YORK EYE AND EAR INFIRMARY, reported by W. A. BARTLETT, M.D.

NUMEROUS patients come to the infirmary, during the out-door bathing season, with distressing pain and noises in the ear, usually of unaccountable origin until questioning about getting sea-water in their ears brings out the fact that they have been disporting themselves in the surf, swimming, or diving. Even then some are surprised or incredulous to learn that, in struggling in the boisterous waves, one may experience unheeded the dashing of a heavy breaker against the side of the head, coming with sufficient force to drive the irritating cold salt-water into the ear and bruise the drumhead by its impact, thus setting up inflammation, or to even rupture that delicate membrane outright. The contact of the briny fluid, which often holds in suspension quantities of sand and small marine shell, while lying in the outer ear against the drumhead, may also give rise to inflammatory trouble. But it is still more incomprehensible to the ordinary bather that the water, which sometimes enters the open mouth or nasal passages while he unguardedly exposes these back-door portals of the ear, so to speak, to an incoming wave, possesses sufficient momentum to force its way up the Eustachian tube to the middle ear. This is an accident to which he is also liable from strangulation while diving or playing in the water, and the ear-drum is much more liable to be seriously affected in this manner than when deluged by water from without.

Of seven acute cases, ranging in age from eleven to sixteen years, selected out of many recently treated at the infirmary, only one of them recalled any previous ear trouble. All of them were males. Women seldom disport themselves violently as bathers, but men and boys often behave most rudely, and frequently, from protracted sojourn in the water, come ashore much exhausted.

In four of these seven typical cases the ear had been injured by the entrance of water *via* the Eustachian tube, since it appeared that they had been strangled and had sniffed water up the nose, causing much coughing and sneezing. They had likewise experienced immediate discomfort in the ear.

In the other three cases the damage had been done by the entrance of water into the external auditory canal from without; and in one of these water may have entered from both directions.

Sometimes recovery takes place spontaneously at this stage, leaving slight or no trouble, but persons with nervous exhaustion, or run down from any cause, cannot always thus escape.

If the trouble, however, advances, as was the case in the patients above alluded to, following the uncomfortable feeling of "stuffiness" or "water in the ear" almost always described as being immediately experienced is more or less pain in the organ, and perhaps deafness; the latter, usually but slight, is generally disregarded when the pain is severe.

The urgency of the symptoms in these seven cases must have been very great, for most of them were obliged to leave off work sooner or later; three of them came for relief the day following the injury, two came the fourth day, one the fifth, and one the fourteenth day.

In five of the cases inflammation was almost entirely limited to the *attic of the tympanum and contiguous parts;* in these *there was no discharge from the ears* whatever escape of secretions there was took place through the Eustachian tube to the throat. In these cases characteristic appearances of the membrana flaccida gave evidence of the seat of the trouble; it was inflamed—in some instances distended as well. Where the process extended further the adjacent canal-walls

were tumefied, or even the seat of an incipient dissecting tympano-mastoid process. In some, mere exudation showed itself as larger or smaller cysts on the membra vibrans. Pent-up secretions were the cause of greatly increased pain, and autophonia, and sometimes of a feeling of "numbness;" and as the periosteal inflammation extended both internally and externally, the severity, of course, proportionately increased.

Prompt surgical treatment was employed in three of the cases, giving vent to secretions in the attic, and assuring future drainage. Two of the attic cases drained spontaneously, and did well without operative treatment. In all of them rest was advised, and local dressings and constitutional treatment adopted as required. In two of the seven cases the atrium was the principal seat of disease; one of them began to discharge in thirty-six hours, the other in two weeks, spontaneously.

It is usually these attic cases that show such a strong tendency to take on severe symptoms and involve the mastoidea; but when drainage is early secured, with proper constitutional and local treatment, the more severe may generally be prevented. Thus two of the attic cases were cured in two days, one in three days, one in fourteen days, and one in twenty-six days. The atrium cases were cured in eight and thirty-nine days, respectively—the latter being complicated with other troubles.

Persons may nearly always escape the injury to which the ears are liable in bathing by the observance of a few simple precautions. They should not expose the face or ear to incoming waves, especially such as are just "breaking" at the height of the head—*i.e.*, they should be on their guard not to be caught unawares. In floating upon the back water is liable to trickle in the canal of the ear, and in diving it also enters easily. Such a result may be prevented by wearing non-absorbent cotton or sheep's wool in the opening of the ear.

On coming out of the bath no time should be lost in wiping out any water that may remain in the canal, and drying the parts; this may safely be done by rolling a small bunch of the fibres of absorbent cotton-wool on the end of a "parlor" match, from which the ignitable portion has been burned. The cotton should project well over the end of the stick to protect it, and form a brush resembling those made of camel's hair. This brush may, with care or after proper instruction, be carried by the bather himself down into the ear for an inch, or until felt impinging on the drumhead; the use of one or more will remove all moisture, and probably prevent any further injury liable to occur from the presence of such an irritating fluid as sea-water.

QUININE IN THE TREATMENT OF WHOOPING-COUGH.

Dr. Ernest M. Lyon, of Newark, N. J., referring to a recent notice of the use of quinine in pertussis, writes:

"I have used it extensively and successfully in my own practice, as follows: ℞. Quiniæ bisulph., ʒ j.; elix. simplic. rub., U.S.P., ℥ jss. M. Sig.—Teaspoonful to a child aged five years and upward. I give it every three or four hours until cinchonism ensues, and keep the patient continuously under its influence, my guide for its administration being the frequency and severity of the paroxysms. By this means I feel assured that I have succeeded in favorably influencing the course of the disease, and shortening its duration in a majority of cases. I use the bisulphate because it seems to me it is better borne by the stomach, and in solution for the more accurate division of the doses. My experience has been that children do not object very strongly to the taste after taking it a few days. After each dose I give a lump of sugar saturated with lemon-juice, and always upon an empty stomach. I kept three of my own children cinchonized almost continually for nearly two weeks without any bad effects."

Progress of Medical Science.

Rheumatic Hyperpyrexia.—The sudden supervention of hyperpyrexia in the course of an attack of acute rheumatism, associated as it is with delirium and other nervous symptoms, constitutes a most formidable complication and one that requires very prompt treatment in order to avert a fatal issue. The symptoms of such a condition, which was usually supposed by the older writers to be a sudden metastasis of the rheumatic inflammation from the joints to the brain, are summarized by Dr. Henry Barnes in the *Edinburgh Medical Journal* for July, 1886, as follows: "There is great thirst, with a dry brown tongue; anxiety, restlessness, and insomnia; a dry burning skin, or more frequently profuse perspiration; often a miliary rash, the vesicles resting on an injected base, giving the skin a mottled appearance, sometimes mistaken for the rash of typhus; the joint pains may persist, or there may be a sudden cessation of them; there is acute delirium, followed by stupor, coma, and sometimes by convulsions. The temperature may rise from 104° to 110° or 112° in a few hours. The general condition of the patient resembles one suffering from typhus. Cardiac complications may be present or absent, but if present, are usually slight in character. As a rule, the degree of pyrexia in rheumatic fever bears some proportion to the number of joints affected and to the intensity of inflammation. In ordinary cases the temperature runs up to 102°, or even higher, on the first day, but there is no typical range. Evening exacerbations may bring it up to 103.5° or 104°. There are sometimes periods of intermission. The onset of complications is usually attended by a rise in the temperature, but this is never great unless the case turns out to be one of hyperpyrexia with delirium. The onset of grave symptoms is usually sudden. Dr. Wilson Fox collected twenty-one instances in which the temperature rose suddenly from 102° or 105° to 109°, 110°, and 111°, and where the duration from the date of the rise of temperature to death was in one case only two hours (103.5° to 109°); in another, four hours and a half (104.8° to 109°); in another, seven hours (105° to 110°); and in a fourth, eight hours (102.2° to 109.5°). In eleven cases the period varied from nine to sixteen hours. The symptoms may come on at any period of the disease, early in the case, when the articular inflammation is at its height, or when convalescence is established. The post-mortem appearances are similar to those found in typhus and other forms of blood-poisoning. There are no marked visceral lesions; there is rapid decomposition of the body; dark fluid blood; staining of the lining membrane of heart and large vessels; hypostatic congestion of lungs; a large soft spleen; granular degeneration of heart and voluntary muscles." Dr. Barnes relates the history of a case of this nature in which the good effects of prompt treatment are well illustrated. The patient was a girl, aged twenty, who was suffering from rheumatism involving a number of joints. The case progressed slowly, without anything worthy of special note, until the ninth day, when the temperature suddenly began to rise. As soon as it reached 106°, wet packing was commenced by means of a sheet wrung out of cold water. As the temperature did not fall rapidly, ice was added to the water, and lumps of ice were rubbed on the outside of the sheet. This had the effect of reducing the temperature within an hour to 99°. During the process of packing the patient became more conscious, and seemed to enjoy the cold pack very much. Toward the end, after nearly four hours in the pack, she felt rather uncomfortable and chilly. The temperature subsequently did not rise above 101.3°, and, with slight interruptions, the case progressed favorably, and the patient made a good recovery. As a practical result of his experience and studies, the author urges that in all cases of acute rheumatism, as soon as there is any indication of nervous

symptoms, and particularly in patients of a high degree of nervous susceptibility, a careful watch should be kept on the temperature, and it should be taken at frequent intervals. As soon as it shows a tendency to rise to the hyperpyrexia range, preparations should be made for the external application of cold. The dangerous symptoms may be sudden in their onset, and drug-treatment seems to fail to arrest them. The question as to what point the thermometer should reach before cold is applied is an important one, and the general condition of the patient will also have to be considered before coming to a decision; but in general Dr. Barnes recommends that it should not be allowed to rise above 105°, as the chances of success appear to be greater the earlier the cold-bath treatment is commenced. Of all means of applying cold, the graduated bath gradually cooled from 90° to 70° is the best, but as this is not always available, the cold pack, ice-bags, or cold affusion may be tried. Frequent testing of the patient's temperature is necessary during the process, and as soon as the reduction of temperature to 100° or 99° is effected, the treatment should be suspended, the patient should be placed in warm blankets, or otherwise dangerous symptoms of collapse may supervene.

The Use of Esmarch's Bandage in the Production of Anæsthesia.—M. Chandelux recommends the previous application of Esmarch's bandage when it is desired to produce local anæsthesia by means of the ether spray. He was led to make use of this procedure by the observations of M. Horand in 1867, who found that the difficulty of anæsthetizing a part bore a direct relation to its vascularity. The author claims the following advantages for his method: 1, anæsthesia is produced in from twenty to forty seconds, while by the ordinary method two minutes or more are required; 2, after the spray is discontinued the anæsthesia remains for about three minutes, since the parts are not warmed by the blood-current; 3, the operation—for example, the removal of an in-growing nail—is greatly facilitated by the absence of hemorrhage.—*Bulletin Général de Thérapeutique*, June 15, 1886.

Cure of a Lingual Ulcer by Galvanism.—Dr. Meyer has employed the galvanic current with success in the treatment of a very painful ulcer of the tongue which had existed nine years. The current employed was of sufficient strength to be felt without causing any pain. The positive pole was held in the hand while the negative pole was applied for thirty seconds to the most painful points. The pain was quieted for several hours after the first sitting. The treatment occupied about eighteen months, with two intervals of six weeks each. The total number of *séances* was one hundred and ninety. A perfect cure was reported to have been obtained.—*Journal de Médecine de Bruxelles*, June, 1886.

Hemi-rheumatism.—Dr. Casalis has recorded the results of the examination of a large number of cases of chronic rheumatism, and states that in a large proportion of them the articular manifestations were localized on one side of the body (*Journal de Médecine et de Chirurgie Pratiques*, June, 1886). This predilection for one side was so marked that he considered it to constitute a special variety of the disease, which he called hemi-rheumatism. These facts, he remarked, would seem to lend weight to the theory which has been suggested, that the central nervous system plays an important part in the production of chronic rheumatism.

Contusion of the Lung.—Dr. T. Piéchaud relates the following case: A man, about thirty years of age, who was driving a cart-load of pigs, came into violent collision with another vehicle and was thrown from his seat on to the pavement, with one of the animals falling on his chest. He experienced intense pain at the moment; this continued, together with great oppression at the chest and profuse frothy expectoration of blood. A minute examination failed to detect fracture of the ribs. No emphysema was discovered. About the middle of the right lung, posteriorly, there existed a tract of absolute dulness to the extent of several centimetres, with complete absence of respiratory murmur, and a marked tubular breathing. Above and below this zone air entered the lung freely, with a slight amount of crepitant *râles*. It was evident this zone of dulness from which the air was excluded corresponded with contusion and rapid sanguineous infiltration of the parenchyma of the lung. The progress of this case was favorable. Three days after admission to the hospital there was entire absence of fever, the pulse was calm, respiration normal, panophysis greatly diminished, and shortly wholly ceased. The symptoms, course, and result here obtained, when compared with those of inflammation or of laceration of the lung, leave no doubt that the lung in this instance had been only severely bruised. The patient was fortunate enough to escape the complications which commonly follow injuries to the chest. The only therapeutic measures adopted consisted of rest, astringent beverages, and opiates. Recovery complete.—*Provincial Medical Journal*, June 1, 1886.

Poisoning from Sorrel.—A curious case of poisoning is reported in the *Hospital Gazette* of June 19, 1886, the chemical features of which possess especial interest from a medical jurist's point of view. The victim of the accident was a boy five years of age, who gathered and ate a quantity of sorrel growing in the vicinity of his father's house. Subsequently the symptoms to be expected from the action of the poison contained in the leaves set in, and, to quench the thirst from which he suffered, the little fellow swallowed a quantity of soapy water which chanced to be within his reach. Death speedily ensued and, post-mortem, the stomach was found to contain oxalic acid in considerable amount. The action of the alkali in the soap swallowed had resulted in the production of soluble oxalate, by absorption of which the fatal event had been precipitated.

Chromic Acid in Granular Lids.—M. Darier states (*Revue Clinique d'Oculistique*, May, 1886) that, observing the good effects of applications of chromic acid to granulations of the pharynx and neck of the uterus, he determined to try it in granular inflammation of the conjunctiva. He takes a brush dipped in an aqueous solution of chromic acid crystals, and after having wiped away the tears covering the palpebral conjunctiva, touches lightly the affected points, but only these. In this way he obtains a desquamation of the epithelium, but never has to fear a deep eschar. The pain following the application is only temporary. The applications may be repeated daily, but M. Darier prefers to make them at several days' interval. He uses the chromic acid five or six times during the course of treatment, making applications in the intervals of glycerole of sulphate of copper. The effect of the latter is, he says, greatly enhanced when it is employed in this manner. He used chromic acid with good effect in a number of cases of old trachoma which had resisted every other mode of treatment.

A Two-pound Child.—Dr. S. L. Post reports in *Daniel's Texas Medical Journal* for June, 1886, that he delivered a woman, twenty-three years of age, and the mother of three children, of a fœtus weighing only two pounds. There were no pulsations in the cord, which was cold and atrophied and wholly detached from the placenta. After diligent work the child was made to breathe, and it is now as well as any infant. The woman menstruated regularly during her entire period of gestation, and during the last four weeks flooded so profusely that she was unable to attend to her domestic affairs.

Disinfectant for the Mouth.—Thymol, 5 grs.; benzoic acid, 3 ss.; tincture eucalyptus, 3 iij.; water, Oj.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, August 28, 1886.

RECENT CONTRIBUTIONS TO ELECTRO-PHYSIOLOGY.

IN the Lumleian lectures, recently delivered in London by Dr. Stone, several of the problems of electro-physiology were dealt with, and some decidedly radical views were expressed. We have not space to enter critically into an analysis of Dr. Stone's opinions, but it may be said that many of them will not be received without considerable opposition.

The lecturer first showed that the discovery by Professor Hughes that the telephone can be used for the estimation of electrical currents may be utilized in electro-physiological studies. He next took up the question of the electrical resistance of the human body. By using large lead electrodes wetted with salt water the resistance of the skin was almost abolished, and Dr. Stone then found that the resistance of the other tissues was only about one thousand ohms, a much smaller amount than has previously been given.

We do not see, however, that Dr. Stone's discovery or correction is practically of any great moment, since, in fact, the skin resistance must always be taken into account.

The learned lecturer, indeed, seems even to think that the skin is not one of the tissues of the body. His experiments upon the resistance of the body in disease, however, are very interesting.

In dropsy it was found that the resistance was diminished; in one instance, as Dr. Stone ascertained, even to one-half. In six cases of hemiplegia, with contracture, the resistance was much less on the paralyzed side of the body. Again, in impregnations of the tissues by various metals the electrical resistance was much altered; mercury had a decided influence in diminishing it, as also had copper, while the influence of lead was but slight. Further studies in this direction are much to be desired.

In the passage of electricity through the body chemical decompositions take place, and electricity is developed and stored. One of the most striking of Dr. Stone's experiments were in this line, showing that the human body may be made a kind of storage battery. For example: In a case of old-standing sciatica, with wasting of the leg, and in two of diabetes, it was found that by charging the body with a moderate strength of constant current for half an hour a considerable discharge took place from the body, which might last for several hours. The first and largest discharge that occurs after the body has been charged is probably to be accounted for as a phenomenon of self-induction; but the less marked though longer discharge is most probably due to electrolysis.

Dr. Stone is very sceptical as to the correctness of present views regarding electrotonus; but while he apparently shows that these views do not express the exact truth with regard to the relations of electricity to nerve-function, he does not substitute any very clear explanation of what these electrotonic phenomena depend upon. We are quite willing to be shown what is wrong, but it would also be pleasant to learn what is right. A fact, not entirely new, is stated with regard to induced currents, viz., that the resistance of the human tissues to them was much less than to the constant current (600 ohms to 1,160). Dr. Stone also says that he has been able to measure the strength of induced currents. "The most available instruments for this purpose," says Dr. Blackwell, "are Hartmann's unifilar dynamometer, which Dr. Stone employed, and Kohlrausch's combined meter-bridge and induction-coil. When the resistance in the circuit through the human body, the Kohlrausch apparatus being employed, is balanced by an equal resistance through the bridge in derivation, the telephone (substituting the galvanometer) becomes silent."

THE FUNCTIONS OF THE TONSILS.

DR. R. HINGSTON FOX, in the July *Journal of Anatomy and Physiology*, discusses the functions of the tonsils and advances some interesting ideas in regard to them which to many will also be novel. These adenoid glands belong to the digestive and not to the respiratory function, the air respired through the nose passes through the pharynx posterior to them, they, when the mouth is closed, resting against the tongue and shut off from the pharynx. They are not, the writer contends, to lubricate the fauces and aid in deglutition as has been claimed. From their structure, which is similar to the solitary agminated glands in the intestine, he reasons that their function is absorbent. He announces his belief that "the function of the tonsil is connected with the stream of saliva which is poured over it, without cessation, day and night," absorbing from the saliva in the intervals of meals certain of its constituents which would be otherwise wasted. The adenoid tissue of which the tonsils are composed may be regarded as the birthplace of leucocytes. The materials, according to this theory, which might be wasted by the stomach, are intercepted by these glands, and made to minister to the growth of white cells.

He closes his article with this explanation of the atrophy of the tonsils which takes place in middle and later life:

"Adenoid tissue everywhere is more largely developed in childhood, when not only nutrition but growth has to be provided for, than it is afterward. And there is nothing surprising in the fact that these nurseries of young leucocytes (permit the fancy), planted here as it were by the river side and drawing their sustenance from the nutrient stream, should dwindle in later life when the demand for white cells has become much less."

The writer does not discuss the effects, if there are any, which the removal of tonsils in childhood, a not infrequent surgical operation, might occasion.

THE CURE OF TRAUMATIC TETANUS.

In a recent newspaper account of a case of traumatic tetanus cured by morphine and stimulants, the physician in attendance was reported, we hope incorrectly, as saying that it was "the only case of cure of traumatic tetanus in the history of the world." This statement, if it was made, was of course an absurdly wild one; but it is nevertheless true that traumatic tetanus is a very serious affection, and genuine cures are of sufficient rarity to deserve being reported in medical journals.

In *The Lancet* of June 12, 1886, Mr. William T. Jackman reports briefly a case of tetanus which recovered under the influence of the new hypnotic, urethran, in conjunction with chloral hydrate. The patient presented well-marked symptoms of tetanus, resulting from a crushing of a finger between two cog-wheels. The trismus was complete and opisthotonus was well marked. Severe paroxysms of pain, greatly exaggerated at night, were complained of. Chloral hydrate in twenty-grain doses every three hours was ordered, but had no other effect than to relieve the paroxysms of pain somewhat during the day. As no abatement of the symptoms was apparent after ten days of this treatment, it was resolved to discontinue the chloral at night and to substitute urethran in four-grain doses every two hours from 6 P.M. to 6 A.M. The first night of this treatment showed a marked decrease in the severity of the symptoms, and from this time the patient made a gradual and uninterrupted progress toward recovery.

A case of traumatic tetanus, cured by large doses of whiskey, was reported in The Record not long ago by Dr. Hobart Cheesman, of this city. But while, in the absence of other means, it would be proper to exhibit large amounts of stimulants, and the newspaper writer above referred to seems to have resorted largely to this agent, such a drug as urethran, if equally efficacious, would for many reasons be far preferable. In the case of Mr. Jackman the failure of the chloral hydrate to relieve the severe symptoms, and the noticeable improvement under the influence of urethran, would seem to point to the latter as likely to prove a very valuable drug in the treatment of tetanus, and would certainly warrant its further trial in this stubborn and dangerous disease.

LA PERLÈCHE; A NEW PARASITIC AFFECTION OF CHILDREN.

Under the above title, Dr. Justin Lemaistre, of Limoges (*Journ. de la Société de Méd. de Haute Vienne—Le Progr. Médical*) describes a peculiar skin affection very prevalent among the children in and about the city of Limoges, and probably in other provinces of France. Among 5,500 school-children examined, 312 were found affected, while in the village of Périgord over half had the disease. It is called by the peasants *perlèche*, because the sensation of dryness and smarting causes the patients to lick (*pourlécher*) their lips. It is also called *bridon*, because the commissures of the lips are cracked or excoriated so that they look as if bridled. It is at these points that the disease is chiefly located. The epithelium becomes blanched, macerated, and detached. Sometimes cracks are formed in the direction of the commissural fold. These may bleed and cause pain. The lesion recalls many of the objective appearances of certain mucous plaques. The disease is self limited, lasting only from fifteen days to a month as a rule; but it may reappear again and again, so that sometimes a child will suffer for a year. The disease is perfectly devoid of danger, and causes no constitutional symptoms. M. Lemaistre has clearly shown that it is contagious, and that the ordinary mode of contagion is by school-children drinking from the same cup.

Upon these cups, in the drinking-water, and upon the infected surface of the skin, M. Lemaistre discovered a micro-organism which he cultivated and called the *streptococcus plicatilis*. In the Pasteur flasks the organism develops with extraordinary rapidity. In examining the diseased skin microscopically, the microbes were found on the borders of the epithelial cells, which often became disintegrated and destroyed.

The microbe lives in stagnant water, wells, and springs, in the form of a micrococcus. When taken into buckets, pails, and unclean drinking vessels, it develops into little chains. In this form it is transferred to the lips, where it develops. The crucial experiment of testing whether this was actually the pathogenic organism of *perlèche*, by inoculating pure cultures was, unfortunately, not tried. So that Dr. Lemaistre's view that it is the cause of the disease does not amount to a demonstration. The *perlèche* is a disease of uncleanliness, and can easily be prevented. Its importance lies in the possibility of its being mistaken for syphilis, and in the annoyance and suffering it gives to children, who are not to blame that their parents and school officials are neglectful.

POISONS IN FOOD AND DRINK.

The current number of *The Forum*, a periodical which has already taken the first rank in publications of its class, contains an article on "Poisons in Food and Drink" by Dr. Cyrus Edson. Dr. Edson has won some reputation for his energetic prosecution of adulterators, and though his work has seemed at times somewhat sensational, he has undoubtedly done good service in the cause of public health. His opinions on the subject of adulterations are very positive.

Beginning with water, he asserts that not one well in a hundred contains water fit to drink. Ice, too, is a source of danger. The idea that in freezing the water purifies itself is a mistake, and, consequently, the ice-supply needs as much looking after as does the water in which it is drunk. The dangers of milk are two-fold. It may be contaminated by a disease, such as tuberculosis, affecting the cow, or diluted with infected water; or it may be skimmed and rendered innutritious by simple attenuation.

Not a week passes, we are told, but seizures are made in our public markets of carcasses of animals that have died from disease. Diseases which cause suppuration affect meat most injuriously. When it becomes known that an epidemic is raging in a certain section, unprincipled dealers

buy up the stock and convert it into beef, mutton, or pork, for the benefit, mainly, of the Knights of Labor and their dependents. Bob-veal, which is the meat of the calf under four weeks old, is innutritious and indigestible, yet it is not infrequently sent into the markets.

Everyone knows that candy is adulterated, but we are told that in making jellies the adulterator reaches the acme of his art. Most fruit-jellies sold to-day are a fraud, being composed of glucose, water, dried-apples, coloring and flavoring matter, and gelatine.

Canned meats and vegetables are, as a rule, safe, unless decomposition has taken place before the cans are closed. Sometimes, also, tinners make cans from tin-plate which contains lead.

Coffee and tea are often adulterated, or "fixed," so as to deceive the customer into believing that the article is better than it really is. The dangers from poisons in food and drink are two-fold, that from accidental contamination and that from deliberate adulteration. To remedy the first, the public must be educated in the rudiments, at least, of hygiene; to correct the second, we need wise laws with proper methods for enforcing them.

News of the Week.

THE DEATH OF DR. ELLSWORTH ELIOT HUNT.—Dr. Ellsworth Eliot Hunt, son of Dr. Ezra M. Hunt, of Metuchen, N. J., died of phthisis, at Pensacola, Fla., August 17th, aged thirty-one years. Dr. Hunt was a profound student and brilliant scholar. At Princeton, where he received his academic education, he was the first and only pupil who won by competitive examination the Steinke prize of $1,500 for languages. Subsequently he secured the fellowship in experimental sciences. He graduated third in his class at the College of Physicians and Surgeons in 1878, served as interne in Roosevelt Hospital, after which he repaired to Vienna to complete his studies. He was but a year and a half in practice when he was seized with pulmonary hemorrhage and was forced to repair to Florida, never to return.

A WONDERFUL OPERATION.—We learn by an account in a recent issue of the *New York World* that another rare and wonderful operation has been performed with brilliant results. This time it was a very painful cancer, situated in the dangerous locality of the breast. The skilful surgeon at the hospital was willing, however, to take all risks to save the life of the patient. The incisions were carefully and judiciously made "in the direction of the fibres of the great pectoral muscle," the slightest deviation of the blade inviting death. The knife was carried "around the diseased mass in such a manner as to include *every part of it*, the lower incision being made first." The pectoral muscle was "thoroughly exposed by the removal of its fibrous envelope." "Strict antiseptic precautions" were observed, and, *mirabile dictu*, the wound "healed by first intention," without any increase in the temperature. All this shows what advances are constantly being made in our noble art by bold and skilful surgeons. We hope, however, that success will not make some of our operators too bold. Who will be the first one to tackle "a wen?"

THE LATE DR. FRANK H. HAMILTON.—At the meeting of the Chicago Medical Society, August 16, 1886, the following were unanimously adopted:

Whereas, This Society has learned, with deep regret, of the death of Dr. Frank Hastings Hamilton, of New York, and,

Whereas, In his death the United States has lost one of its most distinguished surgeons, one of its ablest teachers, one of the purest patriots, and in his private life, one of the most amiable men;

Therefore, Be it resolved by this Society that we hereby give public testimonial to the many virtues of the deceased, and that we tender his family the assurance of the profound sympathy of this Society with them in the hour of their affliction, and that an engrossed copy of these resolutions be furnished them, and a copy spread upon the records.

L. H. MONTGOMERY, M.D., *Secretary*.

NEW CARDIAC TONICS are now appearing with almost menstrual regularity; and it is to be hoped that a climacteric will soon be reached. One of the latest, if not finest, under the name of nitrosalicylate of bismuth, has received the favorable notice of Professor Wagner, who has used it in his clinical practice at Buda-Pesth. It has the advantage, we are told, of being rapid in its action, and never cumulative in its effect. Its only disadvantage is that its effects pass away rapidly when its use is discontinued, and that some patients manifest an idiosyncrasy with regard to it.

PELLETIERINE IN OCULAR PARALYSIS.—Dr. Galeozowski is an ophthalmologist of Paris, the pronunciation of whose name produces a facial spasm, but who, despite his appellative defect, is frequently discovering very wonderful things. Lately he has obtained a curious and unlooked-for result in using pelletierine. Having observed that the muscles of the eye were contracted when pelletierine, or a decoction of pomegranate, was given as a vermifuge, he was led to try the action of the salt in paralysis of the muscles of the eye, supplied by the third and sixth pair of nerves. The results obtained were very satisfactory, paralysis of the branches of the nerves being either cured or much improved after three or six doses, even where, under previous treatment by other means for several months, no relief had been experienced.

THE TREATMENT OF ORCHITIS AND EPIDIDYMITIS found most successful by Mr. F. W. Loudes (*Lancet*) is to paint the affected part with a solution of nitrate of silver (℥ ij. to ℥ j.), with rest in bed, and support to the inflamed organ. One application is generally enough.

INSUFFLATION OF IODOFORM AFTER TRACHEOTOMY.—Dr. G. Shirres found, in two cases (*Lancet*), that the insufflation of ten grains of iodoform every four hours prevents the development and extension of the membrane.

THE BLACK LIST.—The number of institutions in this country whose medical diplomas are not recognized by various State Boards of Examiners is quite large, although fortunately some are now defunct. Here is the latest list: American Eclectic College, Cincinnati; American Health College, Cincinnati; American University of Pennsylvania (Buchanan), Philadelphia; Beach Medical

Institute, Indianapolis; Bellevue Medical College of Massachusetts; College of Physicians and Surgeons, Buffalo, N. Y.; College of Physicians and Surgeons, Milwaukee; Eclectic Medical College of Philadelphia; Edinburgh University, Chicago and St. Louis; Excelsior Medical College, Boston; Hygeo-Therapeutic College, Bergen Heights, N. J.; Hygeo-Therapeutic College, New York City; Joplin Medical College, Joplin, Mo.; Livingston University, Haddonfield, N. J.; Medical Department of the American University of Boston, Boston; New England University of Arts and Sciences, Boston; New England University of Arts and Sciences, Manchester, N. H.; Penn Medical University, Philadelphia; Philadelphia University of Medicine and Surgery, Philadelphia; Physio-Eclectic Medical College, and Physio-Medical College, Cincinnati; St. Louis Eclectic Medical College, St. Louis; St. Louis Homœopathic Medical College, St. Louis; Curtis Physio-Medical Institute, Marion, Ind.; American Anthropological University of St. Louis; Medical Department of Drake University, Des Moines, Ia.; and King Eclectic Medical College, Des Moines, Ia.

THE FRENCH SURGICAL CONGRESS.—The Second Session of the Congress is to be held at Paris this year, from October 18th to 24th. The opening meeting will be held on Monday, October 18th, in the School of Medicine. Four sittings will be occupied with several questions, and at least three with various papers. Communications should be sent to Dr. Pozzi, 10 Place Vendome. The special questions for discussion are: (1) Nature, Pathogenesis, and Treatment of Tetanus; (2) Nephrotomy and Nephrectomy; (3) Orthopædic Resections; (4) Operative Intervention in Irreducible Traumatic Dislocations.

Reviews and Notices.

PSYCHIATRY: A CLINICAL TREATISE ON DISEASES OF THE FORE-BRAIN, BASED UPON A STUDY OF ITS STRUCTURE, FUNCTIONS, AND NUTRITION. By THEODOR MEYNERT, M.D. Translated, under authority of the Author, by B. SACHS, M.D. Part I. The Anatomy, Physiology and Chemistry of the Brain. 8vo, pp. 285. New York and London: G. P. Putnam's Sons. 1885.

THE first two-thirds of the book is devoted to a description of the anatomy of the brain and cord, the remainder to a discussion of its physiology, nutrition, and to certain fundamental points in psychology. There is finally an appendix on the mechanism of expression.

The first chapter contains a very brief description of the development of the brain, and an account of the arrangement of the lobes, fissures, and convolutions. This is essentially the same as that usually given by other writers, but one will find besides much information in comparative anatomy. In the next chapter there is a description of the basal ganglia, and remarks on the general architecture of the brain. The author describes the course of the various fibres and commissures of the brain, and illustrates them with drawings of his torn preparations. To one who had the torn brains before him, the descriptions given by Meynert would not seem difficult, although he is the opposite of a lucid writer, frequently turning aside to discuss or comment upon some point bearing more or less indirectly on his main subject.

The minute anatomy of the cortex is given at some length with the familiar illustration of the five layers, which has gone the rounds of text-books for years.

After this point it must be admitted that the anatomical part of the book is not only difficult to follow, but in the descriptions of the course of fibres and connections and functions of the nuclei of the basal parts of the brain, and of the pons and medulla, the author is not always in harmony with the latest views of other eminent anatomists. This portion is nevertheless instructive to those who already know something of the subject.

The colored cross-section of the spinal cord is, we confess, quite beyond our powers of understanding or criticism.

An extremely instructive and suggestive portion of Meynert's work is that upon the physiology or physio-psychology of the brain. His discussion here is, to be sure, not systematic, and he seems quite incapable of continuously coherent literary expression. Meynert endeavors to explain all psychical processes through the interaction and association of cells, fibres, and end-organs. Every nerve-cell has the property of *sensitiveness*, which is developed in the fore-brain into sensation. Mental processes are the results of the associated activities of these cells, which form a surface upon which impressions of the external world are received.

Meynert is an idealist, and affirms that physiology can teach nothing else. The ego or personality is the aggregate of our memories, and is founded upon and depends upon the structure of our cortex. The will is practically an unknown quantity, but it is not free. Meynert is necessarily a disbeliever in freedom of the will, or rather, with modern psychologists, he discards the term.

The author gives no place to instinct in man. Every act, even that of the sucking child, is a conscious or reflex one.

"The avoidance of the greater pain is the determining motive of all human actions," is another of Meynert's deductions. The feeling of happiness is the result of a mental condition in which there has been excited innumerable actively working concepts, and in which there is an unrestricted flow of associations and a free expansion and running over of nerve impulses.

The cerebral cortex has two tasks—one the innervation of processes of thought and movements, the other the innervation of the vaso-constrictor muscles. When thought is active, vascular innervation is lessened and hyperæmia results, and *vice versa*.

Meynert's psychological suggestions, as we have already said, are valuable and suggestive, but it must be confessed that his views are nearly all old, and that the whole subject has been much better dealt with by Wundt and the modern English school.

The author gives a very interesting account of the nutrition of the brain.

The translator's share in this work cannot be too highly commended. He has performed a very difficult and arduous task in a manner beyond criticism.

The work is well and copiously illustrated.

SUBPREPUTIAL MEDICATION.—The *Medical World* claims advantages in the treatment of gonorrhœa by what is termed subpreputial medication. The method consists in rubbing up morphine and cocaine in lanolin (wool-fat), and inserting it under the prepuce after thorough cleansing. Dr. Taylor claims that this at once relieves all pain by producing complete numbness of the whole organ. He claims that the advantage of lanolin over other vehicles is the readiness with which it is absorbed. He applies sufficient of the mixture for the patient to have one fourth of a grain of cocaine at once; but we think in violent cases this might be increased to one grain or more, since the hypodermatic injection of one or two grains produces no serious results. This is a mode of treatment that leaves the erring Hebrew out of account.

THE Doctor who holdeth his peace impresseth his patient.

FIFTY-FOURTH ANNUAL MEETING,

Held at Brighton, England, on Tuesday, Wednesday, Thursday, and Friday, August 10, 11, 12, *and* 13, 1886.

REPORTS OF SECTIONS.

(Continued from page 227.)

SECTION ON SURGERY.

(Special for THE MEDICAL RECORD.)

WEDNESDAY, AUGUST 11, 1886—SECOND DAY.

MR. ERICHSEN'S ADDRESS ON THE TENDENCY OF MODERN SURGERY.

THE President of the Section, MR. ERICHSEN, Surgeon Extraordinary to the Queen, and Consulting Surgeon to University College Hospital, London, took the chair at 2 P.M., and delivered a presidential address which occupied rather more than half an hour in delivery. He took for his subject "The Tendency of Modern Surgery," by which he meant, he said, the lines that it would be most profitable to follow in the immediate future by those seeking to advance surgery beyond its present lines of undoubted excellence—not the lines that led to success in its teaching, and still less in its practice—but with the advance in all that related to the science and art of surgery. Had they, in fact, reached the final termination of the old routes, and must they follow, if not new, at least less well-explored tracks, if they wished to reach a uniformly higher level? Before answering these questions he would consider briefly the direction in which surgery had advanced since the introduction of anæsthetics into its practice. The discovery of anæsthetics, he reminded his hearers, had been made by an American dentist, working without scientific aid and without any thought of the far-reaching consequences of his discovery. From this epoch he roughly dated the "development of modern surgery." This advance had been in three distinct lines—first, and mainly, in the extension of the scope and in the improvement of the methods of operative surgery; secondly, in the precision, both as to exactitude of performance and certainty in the result of operations; thirdly, in the application of those methods of scientific research by which those sciences are advanced on which practical surgery is based. Dealing in detail with the first of these three, he remarked upon what he said would now be regarded as the horrors—both as regarded physical suffering and absence of sanitary precautions—of the præ-anæsthetic days. The scenes witnessed then the present generation of surgeons could hardly realize. The change that had come over the whole field of operative surgery was more than startling. Operations which Robert Liston—the boldest surgeon and the most skilful operator of his day—would have shrunk from attempting were now daily performed, and organs which were supposed by him to be forever safe from the knife, were now incised or extirpated as matters of ordinary routine practice.

Such had been the skill acquired in recent years that he (Mr. Erichsen) thought there could be little doubt that the final limit had been reached in the direction of all that is manipulative and mechanical, though within these limits there might be much of movement, of change, and of modification. Every artery in the human body accessible to the surgeon's scalpel had been tied, and they had reached the final limit in operations on the arterial system. Every limb had been long since amputated at its highest point; every large joint had been excised. Sculpture, architecture, painting attained their highest degrees of excellence years ago; surgery, he thought, was now in the same position. Turning to the advance in surgical precision, he said there was little left to be desired so far as exactitude of performance was concerned, while precision of result had been obtained as far at least as the wound was concerned. The rules laid down for most operations were so precise that the surgeon could hardly err, the more so as the use of anæsthetics, by rendering the patient insensible to all suffering, made it unnecessary to operate against time, a cause of much fatality in former days. The modern surgeon could assure his patient that there would be no suffering during the operation and no pain afterward, except when the wound was dressed, for any other could be averted by antiseptic dressings. Precision of result, so far as recovery was concerned, was less certain, but here also the gain had been immense, and death after an operation was now looked upon as a rare contingency. Coming next to the application to practical surgery of those methods of scientific research by which those sciences are advanced on which the practice of surgery is based, the speaker showed that the art of surgery had ever been in advance of the science, and that science had too often had to content itself with giving a rational explanation of the phenomena already determined by the art of surgery. What was termed "scientific surgery" was of comparatively modern origin, and dated from the days of John Hunter. Art was final, but science was illimitable. They had yet to learn much from that compound science, biology, in its application to the elucidation of surgical problems—that compound science of modern creation, into which physiology and histology, pathology, chemistry, and physics entered in equal proportions, which worked by means of experimental research; and this was the line of investigation which, he ventured to think, promised the greatest and most useful results to the cultivation of surgery in the future. The speaker concluded by instancing a few of the more important results that had already rewarded scientific research.

At the conclusion of the President's address, SIR HENRY THOMPSON read a paper, introducing

A DISCUSSION ON SUPRA-PUBIC LITHOTOMY.

He said it was a question of what operation was best to remove a stone of large size. Crushing was now considered the best—except for very large stones—but this was not so formerly. Lithotomy was then in vogue, and was attended with great mortality in cases where the calculi were large. Sir Henry Thompson said that at an early period of his career he had endeavored to find some other method than cutting. He gave a graphic description of the effects of removing large stones by perineal operation. After referring to eight deaths as occurring in twenty-five cases of lithotomy, he spoke of a series which were treated by crushing without any death occurring. Lithotomy acquired its repute under Cheselden, who operated mainly on young children and middle-aged adults with stones of medium size. To-day the situation was changed. The lateral operation was always difficult for large stones, and it was for those of exceptional size that the supra-pubic operation was designed. He enumerated

EIGHT ADVANTAGES AS ATTENDING IT.

1. There were no important structures in the line of the incision, or which could be injured by the forceps. 2. The space for manipulation was practically unlimited. 3. There was no danger from hemorrhage, as any which might occur could easily be stopped. 4. The incision was easier of performance, and the removal of the stone safe and easy. 5. The urine left the wound drier and safer. 6. Antiseptics could be used. 7. It was impossible to injure the sexual organs, or to produce recto-vesical, or vesico-vaginal, fistulæ. 8. It was better for large stones. There were but two possible dangers:

The peritoneum might be opened, or extravasation of urine might occurr. He would deal with the latter first. The risk of its taking place was small, and it could only occur from needless interference outside the bladder. No part outside should be approached save in the line of the incision. There was only one way in which it occurred. The stone sometimes emerged spontaneously, the bladder contracting around it. Only one who had met with such a complication knew what to do. In such cases manipulation with the staff might cause extravasation. It was interesting to note that John Douglas made a similar remark as to the use of the staff.

IN THE MODERN SUPRA-PUBIC OPERATION NO STAFF WAS NEEDED.

As to the danger of wounding the peritoneum, that was *nil*. He had never seen this happen, nor even heard of its happening; but even if it did occur, modern resources would enable us to deal with it. The modern method of raising the bladder had the advantage that it aided us in avoiding the peritoneum; but this was not the only benefit of the method.

AN ADVANTAGE OF THE SUPRA-PUBIC OPERATION WAS THAT WE COULD EXPLORE THE BLADDER WITH THE FINGER, NO PROSTATE INTERVENING.

To raise the bladder he used a rectal bag distended. He had never used or advised one containing more than twelve or fourteen ounces. He had lately used and advised a more elongated bag, slightly flattened from before backward. This was introduced as soon as the patient was under ether, and distended with two syringefuls of water from a syringe containing six ounces. The catheter was then passed, and the bladder slowly distended by injecting from six to twelve ounces of weak boracic lotion. It would then form a dull, rounded tumor above the pubes. The surgeon, standing on the left of the patient, then made the abdominal incision from below upward. A separator was used to keep the tissues apart. The stone was removed with the scoop and a finger, or by two fingers without the scoop. He did not advise closing the wound in the bladder completely at the time of the operation, as there would be some risk of forcing urine through the wound. There would be less danger of this in children. A catheter was passed into the bladder above the pubes, and left in from twelve to forty-eight hours.

A CATHETER IN THE URETHRA WAS UNNECESSARY,

and only a source of annoyance. Sir Henry Thompson said he had operated by the supra-pubic method on eleven patients; seven of these were old men. Three were cases in which the stones were very large, one being a stone of twelve ounces. One was a patient with a very large prostate, so large that the bladder could not be explored from the perineum. Sir Henry Thompson concluded by expressing a regret that he had not used the supra-pubic operation sooner, but it was a satisfaction to him to think that he had introduced it into this country soon after Taylor had employed it.

Mr. Reginald Harrison (Liverpool) showed a large stone removed by the supra-pubic method, and in the removal of which midwifery forceps had been employed. For the last twenty-five years he had used lateral lithotomy, he said, and chiefly in children, because he preferred the crushing operation for adults. The mortality in his cases had been only one in twelve, and he did not think better results could be obtained from the adoption of the supra-pubic operation until better evidence than that at present adduced had been brought forward in its favor. It was important to study the subject. He had never met with any serious difficulties in removing by the lateral operation stones weighing as much even as five ounces. Such difficulties as had occurred would not, he believed, have been removed by the adoption of the supra-pubic operation. If, either in lateral lithotomy or in operations on the prostate, the wound continued to bleed, he plugged it with an india-rubber plug exactly fitting it. He kept an assortment of these plugs of various sizes. He concluded by saying that he should be reluctant to abandon lateral lithotomy in favor of the supra-pubic operation, save in the case of stones of very large size.

Mr. Cadge (Norwich) suggested that a middle course between those just put forward might be preferable. He could not forget that Cheselden had tried the high operation, and relinquished it for the lateral one. He would not quote figures, as they were delusive in the absence of all particulars as to age, etc., of patients. He would, however, remark that as yet, so far as he believed,

THE SUPRA-PUBIC OPERATION HAD BEEN PERFORMED IN ONLY ABOUT ONE HUNDRED AND FIFTY CASES IN ALL.

Brodie, though, had a hundred cases of lithotrity before he published his monograph on the subject, which at once captured the profession. We should, he said, wait for further results of the method.

Mr. Jessop (Leeds) said he had only done the supra-pubic operation once. He described the case, and said that he found no difficulty with the operation.

Mr. Barwell said that in boys (and also in girls) the lateral operation presented certain difficulties which were removed by the supra-pubic operation, and the latter was extremely simple. While on this subject he wished also to refer to epicystotomy. There was no doubt that when we had to do with a tumor of the bladder the supra-pubic operation would enable us to remove it easily. He would join issue with Sir Henry Thompson as to

THE DESIRABILITY OF DISTENDING THE BLADDER,

because large stones mostly occurred in old persons with enlarged prostate, and by distending the bladder you also distended the membranous portion of the urethra. This was not always safe in old persons. He did not either approve of distending the rectum in all cases. Mr. Barwell then went on to speak of the relations of the bladder, and reminded his hearers that the peritoneum was not attached to it. As regarded the results of different methods of treatment, he did not think that a very decided numerical superiority could be claimed for any one. In performing the supra-pubic operation he thought it was desirable to sew up the abdominal wound, so as to prevent a ventral hernia just above the bladder.

Dr. Ward Cousins (Southsea) said that the supra-pubic operation had been resuscitated by the attention which had been paid to its details and the use which had been made of antiseptics. Its employment was desirable in cases of encysted stone, and also in cases of stone where the prostate was also enlarged. He described a case in which the patient suffered from stone, enlargement of the prostate, and the hip- and knee-joints on one side were quite stiff. He performed lateral lithotomy, but would certainly select the supra-pubic operation if dealing with such a case again. He thought lithotrity would prove the best for very small stones, and the supra-pubic operation the best for large ones. As to those of medium size the question was as to choosing the lateral or the supra-pubic operation. The former was safe, but was regarded as not being very easy. It was, however, easy if a very sharp knife were used and a straight direction into the bladder kept to. He did not approve of withdrawing the staff (the bladder and urethra being distended) before the bladder was reached by the operator. Such a plan might be safe enough in the hands of Mr. Cadge, but he did not think it a wise one for average operators. Dr. Cousins advocated the use of his (Dr. Cousins') straight staff, and said that with this he did not think the operator could go wrong. This statement caused some amusement.

Surgeon-Major Keegan showed some specimens, and referred to the shorter stay in hospital of children

after lithotrity. As to lithotomy in children, he said that Surgeon-Major Freer had cut one hundred and forty-three without losing one.

Sir William MacCormac said he saw Langenbeck perform the supra-pubic operation years ago in children, and point out its applicability to them. He agreed with Mr. Barwell that vesical and rectal distention were both needless. He referred to a case in which he had performed the supra-pubic operation. The operation was done antiseptically, and the skin wound was an inch and a half long. He removed a stone the size of a marble. He sewed up the wound in the bladder with catgut, then the abdominal wound, and closed the skin wound except leaving a catheter in. The skin wound healed completely in fourteen days.

Mr. Jacobson said we should discuss the operation not for the sake of beginners, but for the sake of those who frequently performed operations. He approved of the supra-pubic operation, as avoiding many dangers.

Mr. Bruce Clarke said he would only touch on two points. First, the use of the bag. He referred to a case (recently reported in *The Lancet*) in which Mr. Thomas Smith performed the supra-pubic operation at St. Bartholomew's Hospital. In this case he had had the advantage of assisting Mr. Smith. The stone could be distinctly felt, before the operation, by placing one finger in the rectum and another above the pubes. On distending the bladder no distention of the rectum was found to be necessary. The other point was as to the healing of the wound. He had seen four cases in which the wound did not heal easily. Was this because the drainage-tube was left in too long? If so, it would be an important point in the after-treatment to remove the drainage-tube in forty-eight hours, if possible.

Dr. Hingston (Montreal) said lithotrity, where it could be performed, was preferable. But it was not always possible to do lithotrity. Whether to crush or cut should be determined by the size of the urethra, and this was not always proportionate to the circumference of the flaccid penis, as had been supposed. The size of the urethra varied considerably, and each person was peculiar in this respect. He had introduced a No. 6 lithotrite into the bladder of a male child three years of age, and even in one aged only two. He preferred lateral lithotomy as the cutting operation whenever feasible. Sir Henry Thompson had placed the limits of the lateral operation at stones of three ounces. Mr. Reginald Harrison thought that stones weighing as much as five ounces might be dealt with by it. He (Dr. Hingston) thought size rather than weight should be considered; and size even was not the only feature, for we should

TAKE INTO CONSIDERATION THE DEPTH OF THE PERINEUM, OBESITY, ETC.

Taking, however, the weight as the standard, he thought that to place the limit at three ounces was to put it rather low, while to put it at five ounces was making it rather high. He had, though, removed a stone weighing more than five ounces by the lateral operation, but only with difficulty, the operation occupying forty minutes.

Sir Henry Thompson then replied. He repudiated the suggestion that Cheselden set aside the supra-pubic operation. Cheselden continued to perform it. There was something about the disuse of the supra-pubic operation that we had not yet got to the bottom of. He remarked that the supra-pubic operation was very suitable for children. Respecting the choice of different operations for different cases and the fixing of limits, he thought different operators would have different views and find different operations suit them. The personal equation came in surgery as in astronomy. Just as an astronomer knew that, of two observers at different stations, one would see a certain star one-sixteenth of a second before another, so no two surgeons would be exactly alike. He defended himself for bringing forward his cases. Although not numerous, he had deemed it right to do so to elicit opinion on the subject.

SECTION ON GENERAL MEDICINE.

Wednesday, August 11th—First Day.

Dr. Broadbent, of London, in the chair.

The proceedings were commenced by a paper by Sir Andrew Clark, of London, on

CASES WHERE DISEASE OF THE HEART HAD EXISTED UPWARD OF FIVE YEARS.

The opener of the debate said he was about to treat the subject from the personal point of view, and handed round a printed paper containing the history of 684 cases of heart disease that had come before his notice of late years. He could not exactly say that all the cases were thoroughly diagnosed; and no doubt in the short examination he was frequently obliged to give to a case, aortic bruit or mitral murmur might not always be clearly defined. Then again, as to the histories of the cases, patients were often inaccurate, and their reports must be taken *cum grano salis*. None of the murmurs in the list were merely occasional. When to these 684 cases he added the numerous out-of-door patients he saw of an afternoon, it might be imagined what a very large number of persons were going about with valvular disease, and looking very well indeed. Of these 684 cases no less than 272 consulted him for dyspepsia; 57 for rheumatism; 22 for gout; 44 for diseases of the nerves; and 17 for eczema, while only 4 were phthisical. One of the most striking cases of longevity connected with heart disease occurred in the person of the chaplain to the London Hospital, who, being about to marry many years ago, had been examined by the medical officer of an insurance company, and told that he had an incurable disease of the heart. The patient gave up his marriage intentions, and resigned the chaplaincy of the hospital, whereupon the committee granted him a retiring life pension. Fifty years afterward, being still in receipt of this pension, Sir Andrew Clark had to examine him, and found the same bruit present for which he had resigned his post so long ago. In another case, a patient he had seen sixteen years before had a double valvular bruit, but was now in good health after a visit to the West Indies. In another case, a lad was brought to him by his mother to see how his life could be made tolerable, and not with any hope to do him much good, but to know how long he might be expected to live. He had aortic systolic bruit, aortic mitral bruit added, and a large heart. He was, however, in good health, and Sir Andrew Clark advised that he should be sent to a private school. In due time the boy grew up and became a clergyman in Horton, and a most popular preacher, doing a great deal of parish work.

In a fourth case a gentleman came from Manchester to see a London physician, expecting to die soon. A loud mitral bruit was heard. There was no congestion at the base of the lung, and his other symptoms were good. He had a splendid business, but was prepared to live in poverty and quiet. He had been long affected with this murmur, and the advice given was that he should go on as usual with his business. In the fifth case cited, a patient sent for a doctor, and he told him he had disease of the heart. He was told not to go upstairs, and at once became ill through nervousness. He consulted another doctor, and he advised moderate exercise and plain living, so that at the age of eighty-five the patient was still alive and pretty strong. There was, however, another side to this question. A patient, a young girl, had mitral regurgitant disease, and her medical attendant permitted her to take violent exercise. In fourteen

days after the permission the child was carried off by ulcerative endocarditis. There were cases where—especially in childhood, but also in adult life—valvular bruit appeared for a time and disappeared. In the case of a patient brought to him by a practitioner in London, he had given the prognosis that the valvular bruit would disappear, and in a few years this took place. Again, in the case of the sister of the late Dr. Anstie, there were both aortic constriction and diastolic bruits. She was operated on, and in the course of six years subsequently no bruit could be heard. It was impossible not to have some impressions flowing from these facts, and these were that the retention of health was favored by attention to simple physiological laws. Patients must place themselves in the best condition to resist disease. The will must be cultivated to avoid worries, and to secure peace and cheerfulness. Hurry, worry, and disquiet were dangerous to patients with heart disease, and all sorts of irregularities should be avoided, such, especially, as excesses in eating and drinking. Kind mothers often did such patients great harm by wishing to feed them all day long. Over exertion and under-exertion should both be avoided, and the abuse of tea must be avoided. The abuse of tobacco was worst of all in heart disease. Failing strength of the ventricles was much to be dreaded. He concluded that hosts of persons in good health go on living with valvular disease of the heart.

Dr. Gairdner, of Glasgow, said he also would speak only of hard facts, and it was curious that twenty-five years ago he had published the history of many cases of heart disease where the patient had lived for many years in good health.

In the consideration of such cases, it was impossible for the consulting physician to work out the details of the patient's career. In his work on "Clinical Medicine" he had made the remark that auscultators were apt to give far too gloomy a prognosis in heart disease. In that work (p. 568) he had narrated the history of a medical man who discovered that he had mitral regurgitant disease. There was also aortic obstruction; but there was no alteration in the size of the heart, and the patient forgot his disease and lived for many years in good health. In 1881 he had sent to one of the medical journals the case of a man who had existed a lifetime with valvular murmur, and in middle age had had an attack of œdema of the lungs, but recovered, and was still alive and married to a second wife. He enjoyed very good health. In his third case, the patient had walked, in 1861, over the Highlands, although he was the possessor of an aortic-obstructive bruit. He died since that date. In his fourth case, a relative of Dr. Balfour, of Edinburgh, had a bruit, probably congenital in nature and arising from perforation of the septum. The chief interest in the case was that there was a loud murmur present. He was about to marry a second time, and was insured thirty years after the bruit was first detected. The patient died of cerebral symptoms, not clearly connected with the valvular disease. In 1862 he saw a boy with a probably congenital murmur and slight chorea. He grew up and married, and was now forty and in good health. Twenty-five years ago, in his book, he had said that valvular disease in young persons was more rapidly fatal than in adults, and, in reading this, Dr. Watson had differed with him. He now thought Sir T. Watson was right. In the sixth case he gave, a clergyman was told that he had valvular disease of the heart; but he was able to walk over the glaciers in Switzerland. That patient had aortic double-bruit lasting twenty years. In another case mentioned in his book (p 602) a patient with valvular murmur died of pneumonia, and the heart was found to be quite unaltered in form.

In another case of mitral stenosis, probably congenital, of old date, in a woman with a large family, she had lived on in good health, although often with great anxiety. In the last case he mentioned, the patient had mitral stenosis and hemiplegia, and a gentleman had recommended him for insurance; but he, Dr. Gairdner, knowing that that gentleman was consultant to a life office, had sent him thither for insurance again.

Dr. Clifford Allbutt said that the main causes of heart disease were within and without the heart, and this made much difference in the prognosis. Rheumatic fever came in early age, and a young heart would adapt itself much more easily to damage than an old one. In this he agreed with Dr. Gairdner's present opinion, who had sent him his book twenty years ago. He cited the case of a marble mason who had carried on his laborious trade for thirty years with a mitral regurgitant disease. Another gentleman with swelling of the legs was supposed to be in a dangerous position from valvular disease of the heart. He had, however, found that the swelling of the legs was due to another cause, and gave a good prognosis. The gentleman was still alive and well at the age of seventy-four. A Leeds inventor, who had enriched many capitalists by his inventions while he himself had remained poor and hard pressed for a living, had lived for ten years with valvular murmur in good health. The use of tobacco was often most hurtful in disease of the heart, and so was the abuse of tea; but still more dangerous than these was the use of alcohol. Tobacco evils were transient, and so were those of tea, but alcohol was permanent in its bad effects. The mere loudness of a murmur was of no importance.

THE NOISY MURMURS WERE NOT SO DANGEROUS IN THE WAY OF REGURGITATION AS THE MORE SILENT MURMURS.

The most important point in prognosis was the position of the heart's apex and the change made in the current of the blood. When the murmur was slight there was often the greatest danger. The mitral valves usually became diseased before the aortic. Hence aortic murmur meant double murmurs. Patients with heart disease might sometimes be insured.[a] Cases of aortic regurgitant, however, were in danger of sudden death. If mitral disease was known to be free from external complications, such a patient might be insured in an easy schedule without over-high premiums. The outcome of this debate was to prove very comforting, and to show that in all cases of organic disease the prognosis had hitherto been far too gloomy.

Dr. Bristowe cited the case of a lady who fifteen years ago had rheumatism; but, although she had a murmur, was quite in good health. The loudness of the murmur, he agreed, had nothing to do with the prognosis, and many people would lead a far more pleasant life if they did not know that they had such a disease. The late Dr. Murchison had aortic regurgitant disease. He consulted a friend as to whether he should give up practice, and he was advised not to do so. He lived seven years longer. He himself, Dr. Bristowe, if he had valvular disease of the heart, would far rather remain in ignorance of his illness.

Dr. Leach said he had notes of ten cases of interesting valvular disease of the heart. In one there was aortic stenosis after scarlet fever, in a boy, aged six, who was now, at the age of nineteen, quite well. A clergyman, aged thirty-three, had twelve years ago been found by him to be suffering from valvular disease of the heart. In this case he gave a good prognosis, as the tracing was nearly normal in character. Patients with valvular disease of the heart, he thought, should not be advised, as some German physician had lately done, to climb hills as a curative process. They should, however, take moderate exercise. It was, he said, dangerous to insure the life of a man with valvular disease of the heart.

Dr. Bowles (Folkestone) said that, as a member of the collective investigation committee, he could not but think that hæmic murmurs had a meaning. Twenty-seven years ago he saw a woman with valvular murmurs. He gave ten grains of Dover's powder, and the murmur disappeared. Temporary murmurs were of little impor-

tance. A gentleman, aged forty-two, had a temporary murmur. Some murmurs lasted for some time and then disappeared. In relation to aortic regurgitant, the danger in these cases had been rather exaggerated. He knew a lady who had lived with valvular heart disease no less than forty-six years; she eventually died of ulcerative endocarditis and femoral aneurism.

Sir Andrew Clark said he had never had anything to do with an insurance company, but sometimes had been asked his opinion on a doubtful case. He thought such lives were of good prognosis, if the murmur had lasted two years, and there was no hepatic or lung congestion, and the general health good. On these conditions he thought insurance companies might accept such a life. It was better, he agreed, not to tell a patient that he had heart disease. The public was accustomed to take a fault-finding attitude toward physicians, and often called in consultants merely to find fault with their medical man. Whenever, then, heart disease was diagnosed, a friend who was discrete should be intrusted with the information, for the credit of the physician.

NEURASTHENIA.

Dr. Playfair then read a paper on neurasthenia. He said that general physicians were always finding fault with obstetricians for constantly making vaginal examinations of these patients, and he was anxious to admit that this might be the case, and that there were cases of neurasthenia to which this advice was very applicable. This was a disease only of the richer classes, and only seen in private practice. The name was liable to be found fault with. It had been styled myosis inquieta. The neurasthenic patient was one who has broken down, and was as much in need of treatment as a patient with typhoid fever or with a broken leg. It was a clearly defined disease, and required very special treatment. The first case he would cite, and the photograph of which he sent round, was that of a lady forty-three years of age, who had collapsed and could not walk across the room. The disease had lasted three years, and was supposed to be cancer. In two months of careful treatment she was quite cured. In another case, a young lady, aged seventeen, broke down from overwork at school; but by treatment was soon put to rights again. In another case, a man, aged thirty-three, had been on a cattle ranch in the United States, and had what was considered "grass dyspepsia." His weight fell to eight stone, although his height was six feet. He was treated and got splendidly well. There had been a disease named spinal neurasthenia by Cheyne and Witt, but it was not this one. It was a disease of the nervous system and required a distinct treatment, which he had described at the Worcester meeting of the Association, and which was most important, as the tendency of modern medicine was rather, he thought, to diagnoses than toward therapeutics.

Dr. B. Hovell read a paper on the same subject, and cited the case of a lady with pains in her back and great nervous prostration, in whom the uterus was quite normally posited and normal in all its functions. There was no spinal disease. Under rest, tonics, and sea air she got well. A maiden lady, aged fifty-four, had intact hymen and great pain in sacrum, and was cured by similar treatment. Neurasthenia was only too common a disease in practice, and far more common than hysteria, of which he had seen very few cases.

Dr. Drysdale, of London, was sorry the authors had not repeated the details of the treatment, as the majority of practitioners were still in great perplexity as to what the clear diagnosis, and nature, and treatment of the disease was. He hoped, that in his reply Dr. Playfair might give a brief summary of the principal features of this special treatment.

Dr. Hughlings Jackson mentioned cases of this disease which had been greatly improved by the treatment of Dr. Playfair.

Thursday, August 12th—Second Day.

Dr. Broadbent, of London, read his introductory address to the Medical Section, under the title of

SOME INJURIOUS REMOTE EFFECTS OF TREATMENT.

Of course, he said, alcoholic prescriptions and the persistent use of opium were examples of what he meant. Even the bromides in medicinal doses produced acne and transient dementia. Cocaine already was beginning to have its list of victims, and symptoms resembling general paralysis were caused by it. Colchicum and veratria were of great service in gout, and it is necessary to prescribe them to give release from pain in many cases, but it was necessary that the system should afterward be cleared by the administration of alkalies. But the gouty man will go on taking these remedies over and over again, year after year. Diseases were often produced by such conduct in the patients, and high tension of blood in the arteries was a frequent result. Of this he gave cases. In 1885 a man consulted him with symptoms of high tension in the arteries, but whose urine was of good color and contained no albumen. He had ten ounces of blood taken from him. This patient had taken much colchicum for his gout. Painters in London, who were affected with lead-poisoning, also often were subject to gout, as Dr. Garrod has shown, and these men were accustomed to take a number of pills containing colchicum for years.

Diseases otherwise not dangerous were often

MADE FATAL BY LONG-CONTINUED USE OF SUCH DRUGS.

Thus gangrene of the lungs, a very uncommon disease, was comparatively frequent in persons with lead-poisoning who had treated themselves with much colchicum. The system of training called Banting, and which consisted in the eating of nitrogenous matters and abstinence from fats and from fluids, with a good deal of exercise superadded, was not dangerous; but patients often left out the last part and led sedentary lives. Glucosuria in old persons was almost always associated with tension of the arteries. The heart often suffered in such cases, and cures were effected at Vichy and Carlsbad on account of the lowering effect of the waters of these localities on the pulse-tension. The object of the physician ought to be to give happiness and comfort to his patient. There was another class of cases, that of nervous headache in young adults, produced either by irritation or by arrest of the catamenial flow. Such affections often disappeared in advancing years. Sometimes persons, as in France, were proud of their migraine. In many instances these headaches were the result of gastro-hepatic derangement, and careful feeding up and the judicious use of arsenic would effect a cure. He had such a case lately in a very hard-working man, and told him that an enema would relieve him, which it speedily did. One of the most dangerous modes of treatment of disease was to be seen in the case of the treatment of dyspepsia by very restricted diet. Patients often would bring themselves to the brink of starvation in order to soothe the pangs of dyspepsia. After many trials a medical adviser was at length called in, and he, too, was perhaps very stringent in his injunction against some particular kind of food. But dyspepsia was often due to neuralgia of the intestines, and was greatly increased by this same starvation diet. The patient went on taking less and less, until at last soups and biscuit are the whole of his diet. Such patients then become seriously ill and take to bed, when they recovered because enjoined to take a generous diet on account of the weak state which treatment for dyspepsia has brought them. In another series of cases of dyspepsia, cold produced great uneasiness in the intestines in patients when winter approached. Constipation was often one of the symptoms it produced. In such cases it was not the stomach that was in fault. Tonics and good food were indicated, and not low living at all, which did harm.

SOME OF THE EFFECTS OF GALL-STONE.

Dr. Ord inaugurated a discussion on the effects of gall-stones by reading a short paper on this subject. Gall-stones, he said, were often continuously found in patients on whom they caused no symptoms. Was it possible, then, that some persons went on all their lives passing such stones without being even conscious of doing so? Gall-stones of large size might pass into the intestine without any symptoms to the patient. In one case such a stone caused distention of the intestine, high up, and all the symptoms of obstruction. An incision was made in the abdomen, and the intestines gradually examined until a point was come to which was congested and high-colored. The patient died, and a large gall-stone was found a little higher up which had caused the obstruction. Gall-stones might exist without causing any jaundice. A clergyman's wife, a patient of his, had never had jaundice or pale stools. When he saw her, duodenal ulceration was diagnosed; she had a large biliary calculus. In the case of another lady, aged forty, pain in the epigastrium was complained of when she was fasting, and this pain lasted some days. The face was well-colored, and there was gastric catarrh and paroxysmal pains. On pressure on the region where the pain was felt a hard body was discovered, and she passed a very large gall-stone, and shortly afterward another. A gentleman, aged sixty, had biliary colic with jaundice and ague. The quantity of urine was increased, and he suffered much pain. His weight fell, and reached only ten stone from being a heavy man. Then a febrile state of the system supervened. The catarrhal state of the stomach was treated. He had glycosuria, and then passed a gall-stone, after which his nutrition improved rapidly, so that he regained his weight of fifteen stone. He had heard of this patient's death two days ago. A gentleman had attacks of fever, and salines were given. He then passed a calculus and the symptoms disappeared. Glycosuria was sometimes produced by the irritation of the liver caused by gall-stones. A laborer, aged seventy-four, was admitted into St. Thomas' Hospital with aortic obstructive disease and albuminuria. Soon after this jaundice supervened, and glycosuria, produced by the irritation of the liver. Gall-stones were frequently present in patients with malarious disease. Hemorrhage sometimes accompanied the passing of gall-stones through the duct.

Dr. Churton, of Leeds, read a paper on

NON-DIABETIC ACETONURIA.

A lady patient of his suffered recently from acetonuria, and her urine was frequently tested and gave the usual reactions of this condition. The patient had been married for some years and had been subject to frequent attacks of vomiting. She had pains in the right hypochondrium, and then jaundice ensued. Gall-stones were considered to be stopping up the cystic duct. The acetonuria was doubtless due to the irritation in the liver. A man, aged fifty-two, had stricture of the œsophagus, and his urine gave a purple tinge with tincture of steel. A lady with diabetes had also acetonuria and albumen in her urine. The presence of acetone in the urine, said Dr. Churton, was not by any means a fatal symptom; but it was not unlikely that the presence of acetone made the condition of the patient unsuited for operations.

Professor Charcot, of Paris, said that the temperature of the body in paroxysms of biliary colic might rise as high as 40° C. (104° F.). He had no theory to propound in this matter, and would readily adopt that put forward by Dr. Ord, that the fever was the result of nerve-irritation, or that of Dr. Murchison, that it was caused by the production of some chemical poison of the system in the liver. In matters of theory he was inclined often to adopt a little of all kinds. The facts were the main point in clinical medicine.

Sir Peter Eades said that modern practitioners had frequent opportunities of treating gall-stones, owing to the increasing sedentary character of the liver of civilized people.

At present we know that gall-stones might be in the cystic duct, the gall-bladder, or the duodenum, but in the actual state of science it was not possible to differentiate these various positions of the stone.

In future it would perhaps be possible to recognize in what part the calculus was lodged, and perhaps then surgical aid might be called in at an earlier date, and then a simple operation might save life. Our division of gall-stones was into mild cases, and dangerous ones in which the patient might be carried off. Most men had seen examples of both of these groups. Disordered state of the bile was caused, and secondary or tertiary disorders of the other abdominal viscera by sedentary habits. This was strikingly seen in the case of the patients in lunatic asylums who were very prone to having biliary calculus. The disease was occasionally hereditary. Cancer of the liver, too, was one of the causes of gall-stones. In young, nervous women, ovarian irritation might often simulate the symptoms of renal calculus. Renal colic, also, was occasionally caused by ulceration of the ducts. Diabetes occurred after the passage of gall-stones in a patient of his, a gentleman, who passed no less than one hundred and thirteen stones. A lady patient had a tumor of the gall-bladder, but lived for some time, and died of another disease. With regard to treatment for gall-stones, expectation was by no means always good treatment. Chloroform often gave great relief and, of course, also sub-cutaneous injections of morphia. The use of purgatives in such cases was, he thought, bad treatment. In some cases operation might be called for. For instance, a man he had seen became comatose and had acute jaundice arising from the presence of a small calculus in the cystic duct. He died, but might have got quite well had he been operated on.

Dr. Gairdner, of Glasgow, said that his experience had taught him that a possible mistake in diagnosis might occur in thinking that angina pectoris was present, when there were only gall-stones. In one case he had been so fortunate as to make this diagnosis, and it was soon confirmed by the presence of jaundice. Two years ago he had published in *The Lancet* a case where forty calculi had been found in the gall-bladder, although the patient had never had any symptom to indicate their presence. There was no jaundice in the history of the case.

Dr. Clifford Allbutt, of Leeds, said that attacks of biliary colic might occur without jaundice. It was often some weeks after the colic that the calculi were passed. He did not see that the angular form of the stone could have much to do with the occurrence of hemorrhage or other symptoms. Patients sometimes died from the shock caused by the passage of the stone. In the case of a lady who had consulted him for biliary colic he had given a favorable prognosis, but this was not justified as she died very shortly after from such shock. A curious case had been seen by him lately. A gentleman was thought to be hopelessly suffering from obstruction of the bowels, and had been seen by several consultants and given up. He asked to see an old medical friend, who came merely to please him, but was told that the man was nearly moribund. That gentleman passed his finger far up the patient's rectum and came upon something far up, against which he pushed. This had the effect, without his perceiving it, of dislocating a large biliary calculus which was shortly afterwards passed, and after copious stools the patient made a good recovery.

Dr. Savage, of London, read a paper on

MENTAL SYMPTOMS WITH LOCOMOTOR ATAXIA.

He mentioned the case of a patient, lately seen, who shortly after marriage developed ataxic symptoms and then became insane. He had formerly suffered from syphilis. In another case seen by him, a man had been ataxic for some years and then developed insane symptoms. With regard to prognosis in such cases his experi-

ence went to show that locomotor ataxy accompanied with mental symptoms was not more rapidly fatal than ordinary locomotor ataxy. The author created much hilarity by his vivid description of the quaint sayings of such insane patients with locomotor ataxy.

Dr. Ord having briefly replied, a paper was read by Dr. Ralfe on

FUNCTIONAL ALBUMINURIA.

He said that a large proportion of all recorded cases of this affection were seen in young persons. Intermittent albuminuria was not infrequent, and accompanied with increase of urea and bile-pigment. Hæmoglobinuria was the usual cause of it in young males who were also anæmic. The disease was apt to be associated with some amount of jaundice. In cases of hæmoglobinuria there was increase of urea in the urine. Functional albuminuria was only a symptom, and in many cases there was no chronic nephritis. In one case, lately seen, there were sixty ounces of urine passed daily with a specific gravity of 1,022. There was an increased quantity of urea and abundance of hæmoglobine. This disease was common enough, and existed with and without icteric symptoms. The essence of the disease consisted in irritation of the nerve-centres. Such patients had often some hereditary taint. The treatment should be careful and the diet good, but only slightly nitrogenous in character. The use of quinine and iron was indicated, and arsenic was often very useful.

Dr. C. R. Drysdale, of London, read a paper on

THE TREATMENT OF PHTHISIS.

He said it could hardly be alleged that consumption was a curable disease when it could be still said with truth that out of 1,000 deaths occurring in a highly civilized city like Paris every week, 200 were due to consumption and 20 or 30 more to other forms of tuberculosis; that is, between one-fourth and one-fifth of all Parisians die of it. Unfortunately, until two or three years ago there was no clear doctrine as to the nature of the disease. Personally, he had always clung to the views expounded by Laennec sixty-seven years ago, who had at that time clearly shown the unity of the disease and its specific character.

Villemin, in 1865, showed that the disease was also virulent and inoculable. Pasteur explained the meaning of virulent diseases, and lastly Koch, in 1832, put an end to the idea that consumption could be caused merely by debilitating influences, and showed that there is one cause without which the disease cannot exist, and that is the parasite bacillus tuberculosis. Henceforth, then, the therapeutics of phthisis must be sought for in the same direction as we seek for the remedies of syphilis and hydrophobia. That is to say, that antiphlogistics, cod-liver oil, and analeptics were clearly inadequate. Phthisis was due to a specific micro-organism always inoculable on animals, transmissible from the sick to the healthy by means of inhalation of the dried sputum, very frequently propagated by heredity, and, when it is localized in one organ, susceptible of cure without damaging the system. Lastly, so-called scrofulous affections are usually due to the same parasite as phthisis. It was necessary to be unanimous as to the nature of the disease, otherwise it was hopeless to suppose that any great advance could be made in its treatment. The real difficulty consisted in the explanation of the hereditary transmission of the disease. Phthisis was very unlike syphilis on this point, for while the latter disease appeared in hereditary form soon after the birth of the child, phthisis was very rarely seen in children under the age of two years. It was held, however, by some that scrofula in young children was frequently the way in which the transmission of the disease showed itself. The statistics of heredity in consumption were extremely various, ranging from eleven per cent., according to Louis, to fifty per cent., according to Cotton. He, Dr. Drysdale, would be inclined to put the figure even higher than fifty per cent. With regard to the cure of phthisis, it was now well known to all who had paid much attention to the subject that patients every now and then, after being distinctly tuberculous, experienced an arrest of the disease and had lived many years subsequently in satisfactory health and able to transact professional and other business. For many years past he had been in the habit of interrogating members of the medical profession as to the numbers of medical brethren they had known who had suffered in early life from well-ascertained phthisis and who had recovered.

He had heard of many such recoveries under the most varied circumstances. For example, some of the British physicians resident at the Riviera and practising successfully there, had, many years ago, been phthisical. M. Erard had informed him that this was the case with several physicians practising in Algiers. Physicians in Colorado and in the Swiss air-cure resorts narrate the same tale concerning their own cases. Professor Parkes, of Nettley, recovered from a severe attack of phthisis and lived for many years after in good health, although he was eventually carried off by the disease. One physician recovered after a voyage to India. The same facts, although much more rarely, were observed among members of the working-classes. It might therefore be said that phthisis is curable in a variety of circumstances far too numerous to mention. Nevertheless, both theory and experience had shown that the pure air of high mountain districts and of the ocean, both of which localities were free from the impurities existing in inland places and low levels, were the climates, *par excellence*, for the cure of tuberculosis. In a recent visit to Davos, he, Dr. Drysdale, had, by interrogating the inhabitants of the adjacent district, ascertained that consumption does not exist among the natives of the high valleys who reside there. In the district of Langwies, some hours distant from Davos, he was told that no case of phthisis ever occurred. This fact has been over and over again mentioned by Jourdanet with regard to Mexico and Bolivia, by Spengler with respect to the High Alps, and by several authors with regard to Colorado and the Rocky Mountains. To those who could afford it, therefore, and they were but few, a prolonged residence in the High Alps afforded the best chance of a cure. With regard to the more direct treatment of the disease, the prolonged use of small doses of mercury had been tried, but with no good results. He himself had experimented with iodine, but without much satisfaction. It was said, however, that that useful parasiticide had been of great service in the shape of iodoform given in two-grain doses twice or thrice daily. In a recent visit to Paris he had conversed on the subject of the treatment of phthisis with M. Grancher and M. Pasteur, and must confess to a hidden hope that the therapeutics of phthisis must be looked for in the direction of experiments upon animals. Unluckily phthisis is not like syphilis, a disease which can be taken but once; but fortunately it can be transmitted to animals, and may therefore prove to be among the viruses which may be mitigated, as hydrophobia has recently been.

On Friday, August 13th, a paper was read by Dr. A. Whittle, of Brighton, on

THE TREATMENT OF MELANCHOLIA AND INSOMNIA.

In this paper the author desired to call attention to the value of venesection in some cases of melancholia with great arterial tension. This remedy often produced excellent results. A young man, aged twenty, had all the symptoms of high arterial tension. He was well nourished, but had vertigo associated with local congestion of the arteries of the head and great intolerance of stimulants. In some similar cases the symptom of melancholy was very slight at first, but gradually increased and made the patient feel suicidal tendencies. The brain shared in the general arterial disturbance. In the treatment of such cases even neuralgia was not always a counterindication, if the bleeding of the patient had marked symptoms

of arterial tension. Leeching was a good form of depletion in fit cases. He cited the opinion of Dr. Broadbent, contained in some of his writings, to the effect that such treatment was sometimes of great value. He sometimes bled to sixteen ounces. Dr. Broadbent quite corroborated the views put forward by Dr. Whittle, for in fit cases he had found venesection of great service in lowering arterial tension. Some time ago he had prescribed large doses of calomel to a lady with such symptoms, and her daughter said that the mother of the patient had had the same symptoms and had been cured of them by purgatives of an active kind.

Dr. Drysdale, of London, agreed that in cases of that kind depletion of some kind was useful, but doubted the advisability of reviving the custom of venesection which had been so common in his early experience of the medical art. In London, at present, this practice had so completely gone into deseutude that many persons had never seen venesection practised. Chemists, too, sold few or no leeches. He preferred to trust to drastic purgatives in these cases of congestion and high arterial tension.

Dr. Mantle, of Durham, read a paper on

THE ETIOLOGY OF RHEUMATISM,

considered from a bacterial point of view. He mentioned that in the examination of several cases of rheumatic fever in young persons, he had found that minute bacteria were to be found in the blood, which he looked upon as the cause of the symptoms. In a case of gout a gentleman had asked him to examine his blood, and in that case he had found bacteria in the blood. He therefore was inclined to look upon rheumatism as caused by the introduction of such organisms into the blood, and this view of the matter was strengthened by the modern treatment of acute rheumatism. In a case of gonorrheal rheumatism, he had also found a microbe in the blood.

Dr. Drysdale, of London, said that ever since he had experienced the value of salicylic acid in the treatment of acute rheumatism he had been led to the views put forward by Dr. Mantle. Mercury and iodine had proved useful as germicides in syphilis, and salicylic acid and quinine were excellent germicides, so that he had come to the conclusion that rheumatism was a disease like ague, and was glad to hear that Dr. Mantle had seen what he had long believed to exist.

A Question of Diagnosis.—A medical student from a neighboring city writes: "A little incident occurred in this city which I desire to bring to your notice. The case is as follows: A man shot himself, the ball (22-calibre) entering the left submaxillary triangle, and probably taking a course upward, backward, and outward, for the patient complained of loss of hearing in the left ear. There was very little hemorrhage. This occurred about nine o'clock P.M. At four o'clock the next morning a physician was called, and after examining and probing the wound, declared the ball 'had severed the wind-pipe, and, striking the posterior wall of the throat (he probably meant the pharynx), had *fallen into the stomach*.' What I wish to ask is: 1, Is such a thing possible under these circumstances; 2, was there any chance of finding such a small bullet after the lapse of six or seven hours, swelling having taken place; and 3, would it not have been wiser to acknowledge the difficulty, or even impossibility, of finding the bullet under the circumstances?"

Anæsthetization during Sleep.—Dr. John S. Marshall writes to *The Lancet* that he succeeded in producing anæsthesia in a sleeping man by the A. C. E. mixture. The patient was a strong collier who was brought to the infirmary with a fractured thigh. Being worn out with pain, he fell asleep before his leg could be dressed. Dr. Marshall found him asleep, induced anæsthesia, and bandaged the thigh without awakening him.

Correspondence.

THE BRIGHTON MEETING.

BEFORE THE MEETING.

To-morrow will commence the Fifty-fourth Annual Meeting of the British Medical Association and the second of its annual meetings which have been held in this town. The former one took place in 1851 and the Association then numbered only as many hundreds (twelve) of members as it does now thousands. Brighton itself has also greatly changed during the past thirty-five years. For one thing, the population has nearly doubled. So has the number of houses. From what was originally but a small fishing village Brighton has grown to be one of the largest and most fashionable sea-side resorts in the kingdom, with a sea-frontage (including its western extension) of nearly four miles. The making of Brighton is popularly attributed to George the Fourth, who, when Prince of Wales, selected it as his marine residence, and built at a considerable expense the building known as the Pavilion, in which to-morrow's conference will be held. But I imagine that the proximity of Brighton to London has had quite as much to do with its advancement. It is only fifty miles, and since railroads have come in can be reached from the metropolis in but little over an hour. The excellent train-service tempts many city merchants to live here and go to and fro daily by train. Brighton, too, is a remarkably healthy place, though a casual visitor would be inclined to think the contrary must be the case, or so many doctors would not have been induced to settle here. The number of medical men who have pitched their tents here is indeed very large, even bearing in mind the teeming and ever-increasing population. In selecting Brighton as their place of abode, no doubt many of its medical residents have had in view their own health as well as that of their patients. There is generally a fresh sea-breeze to be had here, with plenty of sunshine lighting up the waves of what most visitors to Brighton call "a good bold sea." There is no shipping here, and the surrounding country is very bare. There is therefore some force in the satirical description of Brighton as presenting "a sea without ships, and a country without trees." The extent to which it is patronized by Londoners also caused it to be termed (by Thackeray) "London-super-Mare." Brighton flourishes, however, in spite of the gibes cast at it, and the number of palatial residences built upon its western shore furnishes an index to the extent to which it is patronized by the wealthier classes.

Some four years ago a great scare was created among Brightonians by the appearance in *The Lancet* of an article—or rather a series of articles, for the first one was very speedily followed by others—condemning the Brighton drainage. Here, as at most of our sea-side resorts, the sewage is conducted into the sea. It was asserted that the condition of the main sewer running along the Esplanade was far from satisfactory, that stagnation of sewage in it took place at certain states of the tide, and that sewer-air accumulated in it under pressure under a constant danger of being forced back into the houses. These allegations were denied by the Brighton authorities. Eminent sanitarians were appealed to on either side. The feeling in Brighton ran so high that the Town Council actually proposed to sue *The Lancet* for libel. Wiser counsels, however, prevailed and the law was not appealed to, but the local health authorities bestirred themselves to perfect as far as possible the system of sewerage. That the latter was so extremely bad as some thought could I think scarcely have been ever very seriously maintained when we consider the extraordinarily low death-rate of Brighton. The lat-

ter tended to show that—even granting that the Brighton sewerage was far from perfect in theory—at any rate it worked very well in practice. The ultimate result of the discussion has doubtless been beneficial, though Brighton undoubtedly suffered temporarily from the assault made upon its hygienic resources. I have heard the remark by a Brighton physician that the depression has been permanently felt, a view scarcely sustained by a glance at the crowded streets and Esplanade thronged with fashion.

To-morrow we meet in the Pavilion, a building interesting both in itself and in its associations. It was originally built by George the Fourth to serve as his marine royal residence. When built it was added to successively, then altered, and finally a good deal of it pulled down and rebuilt at an enormous cost. Concerning it Byron wrote:

> "Shut up—no, not the King, but the Pavilion,
> Or else 'twill cost us all another million."

After more than a million pounds had actually been spent upon it, it was finally abandoned as a royal residence and sold to the town for a twentieth of its cost. This was in 1850. It is now used partly as a museum and partly to hold various meetings in, for which its spacious rooms are well adapted. The building, as a whole, has rather a bizarre appearance, and has served as the butt of many wits. Externally, a mingled mass of minarets, cupolas, and turrets is seen; the whole of the interior is decorated in the Chinese style. A separate building, originally used as the Royal Stables, was in 1867, at a cost of £10,000, converted into an assembly room, now termed the Dome. The general meetings of the Association will be held in this building, and as it will hold nearly three thousand persons the accommodation will be more than ample for the scientists now *en route* for Brighton.

Although not actually the county town, Brighton is really the most important town in the county, and as such a few lines about its medical institutions, which are numerous, may interest even a transatlantic audience. Among these I must accord the place of honor to the Sussex County Hospital, as not only the largest and most important medical institution in Brighton, but also the oldest, having been founded in 1828. The building cost £10,000 originally, but numerous additions have been made to it from time to time. One wing of it was destroyed by fire in 1872, but this has since been restored. The hospital is situated at the extreme eastern end of the town, upon rising ground many feet above sea-level, and at some little distance from the sea, but commanding sea-views. At present it consists of a handsome building of four stories, with projecting wings, and more than fifty windows in front. There are about one hundred and seventy beds, and a large out-patient department. The wards are large and airy, some being about sixty feet long by about twenty feet wide, and with windows on three sides, thus securing thorough perflation. In some the centre was occupied by a large chimney-block, in which were placed two open fireplaces back to back, one thus serving to warm each half of the ward. Neatness and order seemed to be the rule throughout the hospital, and I was much struck with the business-like appearance of everything. From what I saw I should judge that a good deal of solid work is done within the four walls of the Sussex County Hospital. At the time of my visit several interesting cases were in the wards. One case made an impression on my mind not readily to be effaced. It was that of a young girl, of only sixteen years of age, who had been admitted for a tumor growing from the head of the humerus. This proved to be a myeloid sarcoma, and the limb was amputated through the shoulder-joint. There seemed for a time to be a fair promise of recovery, but the growth recurred in the stump, and had increased so rapidly that further interference was, at the time I saw her, obviously of no avail. The miserable expression of suffering and despair upon the countenance of the patient, as she sat up in bed with her eyes fixed upon the repulsive wound while it was being dressed, was most affecting even to a professional visitor. Other cases were more encouraging. I saw several cases of amputations and excisions which had done remarkably well. One was in an old woman, seventy-two years of age, who had had the right leg amputated in the lower third for an accident. Cellular inflammation had supervened and several collections of pus had had to be evacuated, but she was doing well when I saw her. A boy whose hip-joint was excised last autumn was getting about the ward on crutches, the limb which had been operated on being kept off the ground by a patten placed beneath the sound foot. He looked rosy and healthy, and there was not only a good deal of movement, owing to the formation of a false joint, but he was getting some control over the limb. Two would-be suicides were in one ward lying in adjoining beds. One had attempted to cut his throat, the other had favored oxalic acid, which he had swallowed to the extent (it was supposed) of an ounce and a half. Both were doing well.

Several eye cases were in the wards. One was of keratitis in a patient the subject of syphilis. Mercury had been administered to him, but without producing any effect. The dose was increased until he took three grains a day (each) of calomel and gray powder, besides having a drachm of mercurial ointment rubbed into him thrice daily. This produced a slight soreness of the gums and a mercurial erythematous rash suddenly appeared, but speedily subsided on the mercurial treatment being suspended for a couple of days. Another patient had had half her eye sliced away by a door latch, but was doing well. A cabman who had fallen off his box on to the wheel, with the result that a large section of his scalp was torn from its natural attachment and left hanging down over his eyes was progressing favorably, his temperature being normal and appetite good, although suppuration had occurred and drainage-tubes were still in. The impression produced upon my mind was that most operation cases did very well and wounds healed rapidly, and that, too, although the surgical staff are by no means unanimous in using antiseptics. Those of them who do use them seem generally to use carbolic acid as the antiseptic agent, and Lister's original system (spray, protective gauze-bandage, carbolic lotion) as the method of applying it. Among the cases I saw which had been treated without antiseptics was one of ovariotomy, which had been operated on nine days previously. Although peritonitis had ensued, with elevation of temperature, the patient had successfully battled through it, and was apparently on the highway to recovery. Total-abstinence principles did not seem much in favor at the hospital, for I understood that a good deal of alcohol was prescribed, though not as a mere matter of routine in every case.

I spent half an hour, not unprofitably, in visiting the hospital museum, which is located in an adjoining building. I saw here a remarkable specimen (skeleton) of mollities ossium, which was shown at the International Medical Congress in London in 1881. The specimen was rendered more interesting from the circumstance that not only the patient's history, but also that of his family, was given in the printed label affixed to the case. It appeared that the patient not only lived to nearly seventy, but also married and had several children, all of whom seem to have inherited the disease. One daughter is described as being constantly in the hospital with broken bones, and another died in early womanhood from the effects of the Cæsarean section. An interesting specimen was shown me of ante-flexion of the uterus, the existence of which has been denied. Only half the specimen is shown, the other half having been presented to the museum of St. Bartholomew's Hospital, London. I noted, also, in one glass case a series of sections of the ribs of insane persons, which were made some years

ago at a time when the frequent occurrence of fractured ribs among asylum patients was creating some comment. The preparations displayed certainly supported the view that the bones of lunatics acquire unusual fragility, for in all of them the compact bony structure had been almost wholly converted into cancellous bony tissue. Among the rarer specimens were also one of dislocation of one of the cervical vertebræ without any fracture, and a unique example of ureteric disease. Comparative anatomy was also not unrepresented. I observed a good series of equine vesical calculi, and a good many skeletons of various animals, including one of an apteryx, which, I was informed, had been presented from the Museum of the Royal College of Surgeons of England, by Professor Flower, in exchange for the head of a spotted New Zealander, of which the Sussex County Hospital was the fortunate possessor. The museum is altogether a worthy monument of the thirty years' labors of its indefatigable curator, Mr. N. P. Blaker.

Retracing my steps along the Eastern Road, I read with some amusement an inscription in a fly-proprietor's window informing me that "Mrs. Linsted's ointment cures all skin and eye diseases." This is placed almost within a stone's throw of the hospital gates. Farther on I pass the spacious Medical Mission Hall, at which out-patients are seen every morning.

I also paid a visit to a very useful institution, the Brighton and Hove Lying-in Institution, Hospital, and Dispensary for the Diseases of Women and Children. This is situated in West Street, only a few doors from the Esplanade, and commanding sea-views. The building is spacious and convenient. There is an extensive out-patient maternity department, but the wards of the hospital are open to receive cases of difficult labor. The wards were comparatively unoccupied at the time of my visit. I saw several cases of uterine displacement, one of cervical malignant disease, and one of pelvic cellulitis, in which an abscess had formed and burst externally near the umbilicus, leaving a very intractable sinus. Antiseptics are used in many cases, though not as a matter of rule-of-thumb in ordinary cases of delivery conducted at the patient's home. I learned that the number of cases of puerperal fever had lately been practically *nil*.

Passing up the steep ascent toward the railway station, I pass on my right an imposing edifice of classic type—the Sussex Eye Infirmary. Some ophthalmic cases of interest are to be shown here during the meeting, and a limited number of beds have been placed at the disposal of gentlemen bringing such patients from a distance, to accommodate them during their stay at Brighton. Such an arrangement will no doubt be very nice for the "interesting cases," who have travelled a good many miles, and very convenient and inexpensive for medical gentlemen bringing them, but what will the governors of the charity say to such a manner of disposing of their funds, admirable as it may be from a scientific stand-point? Adjoining the infirmary is, very appropriately, a depot for the sale of Moon's books for the blind. On the opposite side of the road is the Brighton Throat and Ear Dispensary which, albeit but an unpretentious structure externally, is manned by a staff of three surgeons, and has now been in existence for some years.

Deviating from the main road and making my way up a steep slope, a few minutes' walk brings me to the most ornamental medical institution in Brighton, the Alexandra Hospital for Sick Children. On my way I pass the old parish church, St. Nicholas', connected with which are many interesting mementos. One of these is the grave of Phœbe Hessel, of Stepney, who served many years in the Fifth Regiment of Foot as a private soldier, and received a bayonet wound in the arm at the battle of Fontenoy. Her sex was only accidentally discovered. She was pensioned by George IV., and died at Brighton in 1821, at the age of one hundred and eight years.

On arriving at the hospital I note that it is a structure of red brick, with terra-cotta dressings and mouldings, in the Queen Anne style, and stands in its own grounds of more than an acre. The site is elevated, and I may here parenthetically remark that Brighton is very hilly in parts. The hospital was started in a small way eighteen years ago, in the Western Road, and at first contained only two beds. It owes its life to the exertions of Dr. Taaffe, the present medical officer of health for Brighton, who was not only the founder but one of the active staff for many years, and under his auspices it reached its present degree of prosperity.

The present building was erected in 1880, and opened in 1881 by the Prince and Princess of Wales. On this occasion a gold key of the building was presented to the Prince of Wales by Dr. Taaffe, and the occasion was the first on which such a presentation was made. Golden trowels have frequently been presented when foundation-stones have been laid, but Brighton was the first to start the fashion of presenting a gold key; but having led the way, the precedent has always been followed since whenever a member of the royal family has opened a new building. The hospital contains four wards and can accommodate ninety patients. Nearly all have cross-ventilation and are warmed by central stoves, with flues running under the floors, which are concreted under the wooden flooring. Most of the wards are lined with artificial marble, thus rendering cleanliness easy and absorption of disease-germs impossible. There is a separate block in which out-patients are seen, and also a detached ward for isolating infectious cases. The total cost of the hospital was about twelve thousand pounds, an amount which cannot be deemed excessive, considering the size and beauty of the building and the excellence of the sanitary arrangements.

Brighton also boasts of a dental hospital, a homœopathic dispensary, and, at the extreme east of the town, on the cliff overlooking the sea, stands the Black Rock Convalescent Hospital.

ICE-CREAM POISONING.

To the Editor of The Medical Record.

Sir: In your issue of July 24th an article appears from the pen of Dr. P. A. Morrow, questioning the existence of tyrotoxicon in ice-cream, as lately reported by Dr. V. C. Vaughan, and assuming that the poisoning may be the so-called "vanillism" of the French authorities.

The remarkable coincidence of symptoms in cases of ice-cream poisoning seem to point to an identity between the poisons; this, on the one hand, might be considered a point in favor of "vanillism." If, however, we consider the small quantity of extract eaten with each dish of cream, either this extract, or the poisonous substance entering into it, must be ten times as active as strychnine, or the poison is due to something else. No doubt there are extracts unfit for use, from the fact of adulteration or the substitution of some inferior article resembling the true, but with a single teaspoonful to a gallon, or one to one and a half tablespoonful to five gallons of cream (figures given by an experienced confectioner), it is nonsensical to think of poisoning from such a source.

Assuming four to six ounces of cream to be given in each plate, there could not be more than two to three grains of an exceedingly dilute extract given to each person. Evidence is accumulating daily that there is a substance formed, of an alkaloidal nature, which is a most active poison. This substance is developed in milk, cream, meat, and various articles of food, and hot summer temperature, accompanied by certain atmospheric conditions, seems to favor this. The late case of poisoning from ice-cream in Coulterville, Ill., and the discovery of tyrotoxicon by Dr. Vaughan, confirm a theory I some time since advanced.

In the Coulterville case Dr. W. W. Kane has given the following as symptoms noted in the first patient:

"The patient was eight years of age, and when I saw her she was suffering with a slight chill which lasted perhaps fifteen minutes. The surface of her body was cold, circulation greatly depressed, pulse very rapid and al nost imperceptible at the wrist. . . . While in the chill, and I am told before the chill, there was violent emesis and frequent and exhaustive discharges from the bowels. The depression and cold surface was followed very quickly by a raging fever which reached 104½° F. The patient suffered throughout with a most distracting frontal headache, which seemed to be most excruciating over the superciliary ridges. Violent paroxysmal cramp-like pains in the stomach and bowels was also a very characteristic phenomenon.

"One of my patients, when asked to describe the nature of the pain, said it came on suddenly, the degree of intensity gradually increasing as the bowel seemed to twist upon itself in the manner of a corkscrew, and as the bowel slowly relaxed itself so likewise the pain gradually subsided. The vomiting was very persistent, but in all cases under my observation this distressing symptom subsided, while the violent purgation continued and proved to be the most stubborn and intractable manifestation of the disease.

"At first the ejecta from the stomach, which consisted of the contents of this viscus, were thrown off without great effort of the patient, with the exception of two, whose emetic efforts were violent from the onset, the matter vomited being curd-milk tough as dough.

"After the evacuation of the stomach of its contents nausea still persisted, and the emetic efforts, which were associated with great retching, brought forth a very little greenish serous discharge, evidently containing bile.

"The discharge from the bowels was at first the natural contents, which changed very quickly to a green discharge which resembled very much pounded green grass held together with a slimy sero-mucous fluid. The passages from the bowels followed each other in quick succession, as often as every ten minutes, and at first possessed a very fetid odor, but in a very short time after the onset the stools were entirely void of the least color. In only three or four cases out of twenty-five did I notice a small amount of blood in streaks intermingled with the stools. Menstruation occurred in one patient twenty-one years of age who had only menstruated two weeks previous, and who stated she had always been regular and menstruated every four weeks prior to this period."

I have given Dr. Kane's letter in full, as I shall allude to it later.

The first case of ice-cream poisoning which came to my notice was in the summer of 1883.

On July 25, 1883, in Joliet, Ill., two hundred people were poisoned from eating ice-cream at a picnic.

The symptoms in the cases were almost identically the same as given above. Some of the patients did not recover fully for a week or more.

The cream was made of the best materials—fresh cream, milk, eggs, and corn-starch—and frozen in new tin-lined copper cans. The greatest care was observed in making it. The milk and cream were thoroughly boiled, I was told, but stood a short time before freezing.

As soon as partaken of, or shortly thereafter, symptoms of poisoning were shown, some persons coming down more rapidly than others, and a few, I was told, escaping altogether.

What cream remained—about three ounces—was collected and submitted to me for examination, as well as a batter partly filled with the flavoring, vanilla.

It was thought the cause of the poisoning lay in some mineral poison in the vanilla, but as I examined it carefully I found no evidence to sustain this. Thereupon I took some ten or fifteen drops of the flavoring extract myself, and felt no serious effect from it.

There was no evidence of the smallest possible quantity of mineral poison existing in the cream.

Previous to the examination for mineral poisons I had treated the cream with absolute alcohol, slightly acidified with dilute sulphuric acid. This alcoholic extract I examined carefully, by a method similar to that employed by Dr. Vaughan.

I found no evidence whatever of any alkaloid poison of vegetable origin. I succeeded, however, in separating a small quantity of a crystalline substance which, like Selmi's ptomaines, gave a cherry-red color with concentrated sulphuric acid, and had a reducing effect upon potassium dichromate.

This substance produced a stinging, benumbing sensation, when touched to the tongue.

I succeeded in separating a few needle-like crystals, which could only be seen by the aid of a microscope.

Owing to the small quantity of material with which I had to work, the physiological tests desired could not be made. However, a small quantity of the extractive matter, carefully neutralized and extracted with chloroform, after the evaporation of the chloroform, was given a mouse with some cheese, and death ensued in a short time thereafter.

In my report, which was published at the time, I pronounced the cause of the poisoning as due to a peculiar *ptomaines* produced by the incipient decomposition of the cream, favored by the existing atmospheric conditions and the high summer temperature at that time.

I merely give this as another fact in proof of the announcement of Dr. Vaughan in regard to tyrotoxicon in ice-cream, for I believe the substance I isolated is the same thing. That tyrotoxicon is an actual and not a hypothetical substance has been conclusively proven by the splendid work of Dr. Vaughan, and that it may also be, and often is, formed in ice-cream, milk, and articles of food containing milk, is evident.

Some people delight in clinging to obsolete things, like the Mexicans to the rude agricultural implements of their forefathers, and these same people guffaw at every new discovery, like the eminent Frenchman at Franklin's lightning-rods. But anything as conclusively demonstrated as the existence of *ptomaines* must be accepted.

It appears that ptomaines are formed in many articles of food of animal origin, and that the hot, moist atmosphere of the summer favors this. It is notable that cases of ice-cream and food poisoning occur oftener in the summer than at any other time of the year. Hence too much care cannot be exercised in the selection, preparation, and preservation of articles of food during this season.

The poison produced in food is evidently the product of some form of bacteria, the spores of which must be formed in the atmosphere; hence such articles of food as are the proper media for the propagation of these organisms should not be too freely or too long exposed.

The process by which *ptomaines* are formed commences very soon; often the animal is killed, or the milk or article of food is exposed to the atmosphere, and if the substance is once formed it is not easily dispersed or destroyed by any process except further decomposition. We see that the poison is not a very stable substance, but it is a very active substance.

Cooking of food may suffice to kill the bacteria and their spores, but it will not always suffice to dispel or destroy the poisonous ptomaines.

Unfortunately there is no known method at the present time whereby the people can detect the presence of this poisonous substance. Under these circumstances poisonous articles may get into the hands of the dealer and may be disposed of in perfect good faith. It is the duty, however, of every dealer to observe the best known precautions to avoid all such unfortunate occurrences, and thereby protect his patrons as well as himself.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 15 to August 21, 1886.

MAGRUDER, DAVID L., Lieutenant-Colonel. Promoted to Surgeon with rank of Colonel, vice Brown, retired. July 26, 1886.

ALEXANDER, CHARLES T., Major. Promoted to Surgeon with rank of Lieutenant-Colonel, vice Magruder, promoted. July 26, 1886.

CRONKHITE, HENRY M., Captain and Assistant Surgeon. Promoted to Surgeon with rank of Major, vice Alexander, promoted. July 26, 1886.

WALKER, FREEMAN V., of Georgia. Appointed Assistant Surgeon, vice Cronkhite, promoted. July 27, 1886.

BAILY, J. C., Major and Surgeon. Granted one month's leave of absence. S. O. 111, Division of the Atlantic, August 17, 1886.

BENTLEY, E., Major and Surgeon. Granted one month's leave of absence, and at its expiration to report for duty as Post Surgeon at Little Rock, Ark. S. O. 113, Division of the Atlantic, August 18, 1886.

TREMAINE, W. S., Major and Surgeon. Sick leave further extended six months. S. O. 187, A. G. O., August 13, 1886.

LORING, L. Y., Captain and Assistant Surgeon. Leave of absence granted him in S. O. 59, August 2, 1886, Division of the Pacific, extended two months on Surgeon's certificate of disability. S. O. 189, A. G. O., August 16, 1886.

TAYLOR, B. D., Captain and Assistant Surgeon. When relieved by Surgeon Bentley, to proceed to Jackson Barracks, La., and report for duty as Post Surgeon. S. O. 113, C. S., Division of the Atlantic.

HOPKINS, WILLIAM E., First Lieutenant and Assistant Surgeon. Assigned to duty as Post Surgeon at Angel Island, Cal. S. O. 61, Division of the Pacific, August 6, 1886.

BORDEN, WILLIAM C., Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort Bridger, Wyo., during absence of Assistant Surgeon Crampton. S. O. 100, Department of the Platte, August 9, 1886.

WALES, PHILIP G., Lieutenant and Assistant Surgeon. Relieved from duty in the Department of the Columbia, and to report in person at Headquarters Division of the Pacific for further orders. S. O. 62, Division of the Pacific, August 9, 1886.

MASON, CHARLES F., First Lieutenant and Assistant Surgeon. Assigned to duty as Post Surgeon at Plattsburg Barracks, N. Y. S. O. 113, Division of the Atlantic, August 18, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ended August 21, 1886.

STONE, E. P. Commissioned an Assistant Surgeon in the Navy, August 5, 1886.

WENTWORTH, A. R., Assistant Surgeon. Ordered to temporary duty, Navy Yard, League Island, Pa.

LIPPINCOTT, G. C., Passed Assistant Surgeon. Ordered to Annapolis, Md., for temporary duty, member Medical Examining Board.

A URINAL FOR CASES OF VESICO-VAGINAL FISTULA.

By JOHN C. JAY, JR., M.D.,

ENDEAVORING to relieve the wretched condition of a patient, aged sixty, to whom cystotomy through the anterior vaginal wall had been done for the relief of cystitis, and in whose case it was not deemed expedient to close the fistula, owing to the pathological condition of the urine, I tried every kind of urinal for females that could be heard of, but they one and all failed, it being impossible to apply any apparatus to the vulva and maintain a tight joint.

It occurred to me to combine a urinal with a pessary. This idea, from the first trial, proved more or less successful. I had urinals attached to several kinds of pessaries, but that which gave the greatest, and I may say perfect, success was the elastic-ring pessary. One of these of the proper size was taken to the rubber manufactory, and upon it was built the urinal which is shown in the cut. There are no joints. There is no metal to corrode. A tube-compressor slipped upon the exit-tube gives the patient complete control.

This urinal has now been worn by my patient for four months, and during that time she has not wet the clothing or bed. In her case the ring-pressure has sufficed to maintain the weight of the urinal and the contained urine. At night, however, when a large amount of urine is allowed to collect, when about to rise she is careful to take the weight off the ring by supporting the bag with the hand until it is emptied. In a younger and more active person the weight of the urinal should be sustained by a knitted purse, surrounding the lower half of the urinal and attached by tapes to the waistband. My patient has several of these urinals, and a clean one is introduced every ten days. While in her daily sitz-bath she slips the nozzle of a syringe into the exit-tube and fills the urinal repeatedly with warm soap-suds, and thus maintains cleanliness of the apparatus and vagina.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau. Health Department, for the week ending August 21, 1886:

Typhus fever		
Typhoid fever		
Scarlet fever		
Cerebro-spinal meningitis		
Measles		
Diphtheria		
Small-pox		

AN ANATOMICAL INSTITUTE.—The municipal authorities of Nancy, France, have voted a sum of 3,000 francs, to be added to an appropriation of 500,000 francs by the government, for the creation of anatomical and chemical institutes in that city.

THE TREATMENT OF RHUS POISONING.—Dr. E. Mammen, of Bloomington, Ill., writes: "I have recently treated two cases of poisoning by *Rhus venenata*, on the following simple plan. A four per cent. solution of carbolic acid was used as a lotion, and afterward the following ointment: ℞. Acidi carbolici, gr. x.; acidi boracici pulv., ʒij.; vaseline, ℥j.; applied two or three times a day. The dermatitis subsided promptly. One case was quite severe. The hands, arms, penis, scrotum, and anterior parts of the abdomen were severely involved. The pain and irritation at once subsided under the application, and my patient was well in a few days."

A PHYSICIAN'S INTERESTS.—Dr. Syme says: "There are three ways you may try, there are three interests you have to consider, and it will depend upon the order in which you consider them how success will be measured out to you. The first interest is your own, and it may seem to you the greatest, while it is really the last. The second interest is truly greater, for it is the interest of your professional brothers; but the last is the greatest of all, for it is the interest of your patient, and with that is eternally related the interest of the art you practise."

OVARIOTOMY AND DISEASE OF THE FALLOPIAN TUBES. Dr. Mary Dixon Jones, of Brooklyn, writes: "Spencer Wells is often quoted as having said 'that in not one case among his one thousand ovariotomies had he perceived any sign of disease in the tubes.' Last Saturday, from a woman twenty years of age, I removed two ovarian cysts. The right ovary was converted into a cyst, the size of a small orange; the *tube* was very much hypertrophied, in a high state of congestion and inflammation, and was spread out flat upon the ovary, its posterior surface entirely adherent throughout its whole extent; apparently the tube was incorporated with the walls of the cyst. The left ovary was also converted into a cyst, not as large as the right, and to it was adherent, in a similar manner, the left Fallopian tube, which, like the right tube, was hypertrophied and in a condition of profound disease. Both tubes seemed entirely impervious. I have been more surprised at the observation of Sir Spencer Wells because all the cases I have had of Tait's operation, or of cystoma, while the ovaries were more or less profoundly affected, yet, in each case, the tubes were diseased, and in some, greater pathological changes had taken place in the tubes than in the ovaries. When we consider that the noxious material, or infecting element, must pass through the tubes to the ovaries, is it not reasonable to suppose that they, the tubes, should be first and most frequently affected, though their pathological structure may not show *ostensibly* so great organic changes as we may find in the ovaries? Again, when we think that much of the so-called cellulitis is really tubal disease, and then consider how very frequent is this supposed cellulitis, we may have some idea of the frequency of disease of the tubes, or salpingitis. The young woman from whom I removed the cystoma, three days ago (the patient is doing remarkably well; her temperature the morning before the operation was 99¾°, the day after the operation it was 100⅜°), has been married two years—no children. Externally she had all the appearance of health—good color, well developed, etc.—but since early menstrual life she has complained of great distress in the pelvis, at times very severe. No doubt she had repeated attacks of salpingitis, and these repeated attacks changed the structure of the tubes and caused the inflammatory adhesions to the ovary. There were many peritoneal adhesions, but they could not be severed; to have attempted to have severed the adhesions between the tubes and the ovaries would have been complete destruction of both structures. I must think that in many of Sir Spencer Wells' cases there were diseased tubes; but his mind was so directed to, and absorbed in, ovarian troubles as to gross results that he did not consider minor pathological conditions or microscopical changes. But Sir Spencer Wells does not say there were no diseased tubes in his one thousand ovariotomies, but with the modesty of a great scientific man he said, 'in not one of the cases did he *perceive* any sign of disease of the tubes.' Could his cases be reseen, and especially seen in the light of modern microscopical science, I believe it would be found that many had diseased tubes."

SYSTEM IN RECORDING THE RESULTS OF READING.—Dr. Enos T. Blackwell, of Cedarville, N. J., writes: "Every reader, however tenacious his memory, must often experience an inability to recall at will the special facts gathered in his examination of the periodical literature of the day. Particularly is this true of the busy physician, who snatches his information at detached periods, and while his mind is crowded with the details of his daily practice. If he has no settled plan of recording the data culled from many sources, his time will often be vainly spent in tracing the missing memoranda that he should be able to find and use in a moment. It is to afford aid in this regard that note-taking is resorted to; but this avails little, unless it be associated with some system of easy reference. The 'Index Rerum,' devised by Dr. Todd, fulfils this want exactly, and it is doubtless familiar to many physicians. As it cannot be denied that many remedies are used in an empirical way, it need not wound one's self-love to have at hand a well-arranged index of them, and of the diseases in which they have been successfully used by others. I make some extracts from my own gleanings to illustrate the proposition. We will suppose that a practitioner has a case of mammary engorgement, which threatens to become a breast abscess. Should he not feel fully armed to meet the trouble, he may consult his index for the treatment found effectual by others. On the page marked *Ae*, I find recorded the following: Abscess, mammary—adhesive plaster in, *M. and S. Reporter*, xli., 189; ice in, *Phil. Med. Times*, xii., 214; prevention by fomenting with ammon. carb. in hot water (℥j. to Oj.), *M. and S. Reporter*, liv., 153. Puerperal eclampsia is one of those terrible forms of disease which demands the instant adoption of bold and effective measures. If the physician has not a well-grounded faith in a method of treatment of his own, a few minutes' time avails to refresh his memory with the experience of others. My gatherings embrace the following notes, found on page *Ea*: Eclampsia, puerperal—pilocarpine in (¼ gr. hypodermically), *Phil. Med. Times*, ix., 404; chloroform in, *M. and S. Reporter*, xlii., 233; albuminous, veratrum and diuretics in, *ibid.*, xlii., 280; uræmic, jaborandi and benzoic acid in, *ibid.*, xlii., 821; septicæmic, phenic acid (hypodermically) in, *ibid.*, xlviii., 519; hot pack in (40° to 50° C.), *Med. Bulletin*, v., 107. In order to be sure to find at once what is sought, it is well to record the same data under different headings, *e.g.*, morning-sickness may be noted under the heading of vomiting. In this way the catalogue may be gone through, and something useful be found to meet almost any case that may present itself—information which is the record of researches well tested and found reliable; as also of those which are more recent, embodying the latest suggestions and discoveries of illustrious scientists and practical physicians of extended observation and experience."

HOMO CAUDATUS.—Dr. Elisseyeff reported the following case at the meeting of Russian physicians held in St. Petersburg in April (*Vratch*, No. 16, 1886). A woman, twenty-three years of age, consulted him on account of a projection in the coccygeal region, which had become very painful from the irritation of a bandage which she had used to prevent its growth. The tail was nearly two inches long and over half an inch broad, and was composed of two vertebral segments covered by fat and hairy integument.

CHRONIC DIARRHŒA is said to be speedily controlled in many cases by a saturated solution of common salt in cider vinegar, the dose being a teaspoonful three or four times a day.

ERYTHANTHEMA SYPHILITICUM.

BY EDWARD FENNEL BRONSON, M.D.

PROFESSOR OF [illegible] IN THE NEW YORK [illegible]

A CASE of syphilis recently came under my care which presented features of extraordinary interest to me, not only in that the symptoms were of an unusual character, but in that they represented a phase of syphilitic symptomatology whose etiological bearings afford an interesting subject of study.

The case was the following:

B. G——, aged forty, born in Germany, farmer by trade, entered Charity Hospital, May 4, 1886, suffering with an acute inflammatory eruption of the face, hands, and feet. Upon the face a sharply circumscribed erythema covered nearly its entire area, and extended over the ears and somewhat upon the scalp and neck. The surface was thickly studded with a vesiculo-pustular eruption, which was especially abundant upon the forehead, cheeks, and chin. The vesico-pustules were pretty uniformly the size of peas. Both palms and the inner surfaces of the fingers were covered with a deep-red erythema, which was sharply limited at the borders. All the nails of both hands showed evidence of disease. They were lustreless, rough, rugose, striated, and split or jagged at the ends. One (the ring-finger of the right hand) showed some suppuration in its wall. Upon the soles were erythematous patches similar in color to those on the palms, but of more limited extent. There were three or four nummular spots on each foot, situated chiefly at the inner and central portions of the sole. The toe-nails were unaffected. Scattered over the thighs and legs were a number of small erythematous spots, in the centre of some of which were little pustules. When I first saw the patient, three days after his admission to the hospital, the face was much swollen, most of the pustules had collapsed, run together, and were converted into an exuding, whitish, somewhat elevated, diphtheroid surface, with a very copious, purulent, foul-smelling discharge; while upon the nape of the neck there had appeared a new eruption, similar to that at first observed upon the face. It was a large, sharply circumscribed patch of deep crimson erythema, with numerous white, pea-sized, globular, apparently superficial, vesico-pustules scattered over it. The appearance was like that of a burn or scald of the second grade. There was no marked infiltration of the skin, apparently, other than would accompany any superficial acute dermatitis. Upon the hands and fingers the eruption had become more dusky, almost livid in hue, and the horny layer of the epidermis had begun to be elevated in large, loose, thick lamellar sheets, still attached at the edges, and containing no fluid exudation beneath. Desquamation had not begun upon the feet, and did not for some weeks afterward. On various parts of the body, particularly on the thighs and anterior part of the body, was a disseminated, fine pustular eruption, situated about the hair follicles. At the bases of the pustules there was no noticeable infiltration. Here and there, especially upon the arms, were little dark-red erythematous spots, not raised above the *niveau*, and not perceptible to the touch. There were no lesions upon visible mucous membranes. Aside from general debility and marked anorexia there was little manifest disturbance of the general health. There was no pronounced fever. The eruptions all appeared to be of an irritative and decidedly inflammatory character. That upon the face and neck suggested [illegible]

On the palms and soles the eruption, while partaking of the erythematous character of that upon the head, wholly lacked its disposition to fluid exudation. At this stage of the disease the diagnosis was exceedingly obscure. Its multiform lesions suggested analogies with those peculiar eruptions that have been described by Bazin and Tilbury Fox under the name of *hydroa*, and by Duhring under the term *dermatitis herpetiformis*. The previous history of the case was not very satisfactory. The patient stated that the eruption on his face had existed for several weeks prior to entering the hospital, and that there had been recurrent attacks upon various parts of the body for the past six or seven months. He is married and has had twelve children, eight of which are living and all healthy, including the last born, which is two years of age. The wife shows no sign of disease. His former physician, Dr. Louis Fischer, whom I saw subsequently, informed me that he had treated the patient during the past two or three years for several attacks of eruption upon the skin. The first was a papular exanthem upon the body. This disappeared, and some months later there was a vesicular eruption about the anus, said to be of an herpetic character. It extended about two inches on either side of the anus. The efflorescences occurred in clusters. It gradually passed away and was followed, at various intervals, by other eruptions, either papular or pustular, on different parts of the body. These eruptions were regarded as syphilitic, and always yielded to antisyphilitic treatment. The last time Dr. Fischer saw the patient was about a month before the latter's admission to the hospital, when he was just recovering from an itchy pustular eruption on the scalp and forehead. It dried up with the formation of crusts and scales. Dr. Fischer had never observed any cutaneous affection of the hands or nails.

When I first saw the patient there was not a single lesion that could be regarded as clearly syphilitic. As the disease progressed, however, some important modifications were noted in its appearance. The diphtheroid patches upon the face continued to discharge purulent and very offensive matter in copious quantity for several days, during which time the face remained much swollen. Then, as the discharge became less and the swelling subsided, hyperplastic growths made their appearance. In ten days the secretion had become slight, but the affected regions of the face and neck were covered with prominent warty elevations. Upon the bearded parts they were uniformly distributed, mammillated or papilliform, and closely set together. The red prominences projecting above the purulent matter that occupied the sulci between them roughly suggested the appearance of raspberries and cream. On the forehead and upper parts of the cheeks the growths were smoother, and occurred in circumscribed, round, or oval patches of nummular size. Upon the back of the neck the warts, which were mostly discrete, whitish, and of about the size of large peas, but with flattened surfaces, resembled exactly *condylomata lata* as they occur about the genitals.

[1] Read before the American Dermatological Association, August [illegible]

They occupied only the central portions of the erythematous patch. These vegetating growths were produced within a week from the first appearance here of the pustular eruption. Those upon the neck lasted ten days or a fortnight and then rapidly disappeared, apparently under the influence of a local application of a solution of bichloride of mercury (grs. ij.: ℥ j.). The vegetations upon the face were more persistent. Surrounding the growths, especially upon the forehead, and also those on the back of the neck, the skin over the areas corresponding to the original erythema was of a dusky-red color, with somewhat of a coppery tint, with sharply defined borders, which gradually became more and more elevated and rounded with an increasing infiltration. In the third week following admission to the hospital two red eroded spots, with slightly grayish centres, appeared upon the lower lips. They were of about the size of peas, and looked as though they might be erosions left by ruptured bullæ. In the course of a week or ten days their bases had become so infiltrated as to produce an elevation of a line or two above the surface. They were not unlike mucous patches. In the mouth were no lesions whatever. The orifices of the nares were much occluded by the vegetations and thickening of the skin, so as to interfere with nasal respiration, producing an effect like snuffles in a syphilitic infant.

Certain changes were noted also in the eruption on the body. It became more papular in character, the papules gradually increasing in size. May 17th, "an abundant crop of small papules and pustules, each one occupying a follicle," was observed "on the back, especially in the scapular region." On the back of the shoulders and arms they occurred "in groups of fine papules closely clustered together, resembling a miliary syphilide both in arrangement and color." On the 25th there were a number of papular tubercles on the back and arms, some the size of peas and some even larger, while others were miliary. Some of the papules showed slight desquamation in the centre, where they were somewhat depressed, especially the larger ones, a few of which had little crusts in the centre with an elevated rim of infiltration outside. The pustules had all disappeared. May 31st, the eruptions were everywhere subsiding. The papules and tubercles that were upon the back had left brown pigment stains. June 7th, the condyloma-like growths had disappeared from the nape, leaving dark-colored spots, though the brownish-red discoloration, with its gyrate infiltrated borders, still remained both in this situation and upon the forehead. Upon the upper parts of the face the nummular hyperplastic growths were yet prominent, of irregular oval outlines, generally smooth, though somewhat lobulated, of a paler color than those lower down, and free from secretion. The epidermis over them appeared to be intact. Upon the bearded portions the growths had the mammillated appearance described above, with some purulent secretion. Here and there on the face, neck, and other regions were to be seen a few vesicular or vesiculo-pustular efflorescences. The palms had become smooth, desquamation having ceased, but were still red and without perceptible infiltration. The nails showed little change. The patient's general condition was fairly good. Two weeks later the patient insisted on going out and received his discharge, promising to come and see me at my office. During all this time, notwithstanding so many of the features of the disease were strongly indicative of syphilis, no antisyphilitic treatment was prescribed. The patient appeared to be doing quite well under tonics and regimen, and at the time he left the hospital all the cutaneous affections seemed to be making fair progress toward recovery.

June 18th, the patient came to my office with some relapsing efflorescences upon the face, especially on the forehead and cheeks, and mostly situated upon the hyperplastic growths which had not yet disappeared. The efflorescences were papular in character, of a pale red color, with a certain waxy look, and occurred in groups of curvilinear, crescentic, annular, or orbicular shape. The chin and lower part of the cheeks were still warty and looked congested, as though *the process were about to become more active.* Upon the palms, which remained red, were several circular defects in the horny layer of the epidermis, with a loose fringe of cuticle surrounding them, apparently the remains of syphilitic papules. A few days later the papules on the face had increased, and a pretty abundant papular eruption had reappeared upon the back. There were two places where large papules had been excised two or three weeks before, for the purpose of microscopic examination (which showed the usual infiltration with granulation-cells of syphilitic lesions). Little black crusts remained at these places, and each was surrounded by an elevated rim of infiltration. On the legs were a number of papules covered by silvery scales (psoriasis syphilitica). The patient looked feeble and anæmic, and complained of weakness. Daily mercurial inunctions were then for the first time ordered, and black wash as an application for the face. Five days later a decided improvement was noted, which continued rapid during the succeeding fortnight. The papular eruptions subsided, and also the vegetations; the latter, as they disappeared, left little pit-like depressions at the sites of the hair-follicles. Finally, only a few rough, horny spots were left here and there on the cheeks and chin, and they also soon vanished. There remained a dirty-brown staining of the skin over the forehead and nape for a considerable time after. July 26th, the patient was comparatively free from syphilitic manifestations. The hyperplastic growths had all gone, as well as the papular eruption, and the nails near their matrices appeared to be growing well. The patient complained of "piles," and on examination a fleshy excrescence was found projecting from the anus, of about the size of a large bean, and covered with a mass of filiform warts. Similar warts, occurring in little tufts, were scattered here and there over the margins of the anus. They were all apparently of the nature of condylomata acuminata, and yielded readily to treatment.

The vegetating lesions upon the face and neck in the above case did not correspond to any ordinary form of vegetating syphilide. In appearance, though not in their mode of development, they resembled the *condylomata* (both *lata* and *acuminata*) that occur in moist situations, as about the anus and genitals. They differed from the so-called *framboesia syphilitica* (*syphilis cutanea vegetans*) in that the latter is usually a product of more gradual growth and is generally preceded by ulcerative or other well-marked lesions of syphilis. In their manner of development they suggested the growths in the "herpes vegetans" of Auspitz,[1] and the "pemphigus vegetans" of Neumann.[2] In Alibert's description of the case of Georges Bartos I find some points of striking resemblance to the case detailed above, so far at least as the vegetating lesions are concerned, except that in the former the growth would seem to have been more exuberant. Alibert called the disease "mycosis framboisé." There are, doubtless, various diseases of the skin which may be attended with papillomatous or warty outgrowths. Under just what conditions they may arise is an inquiry upon which I shall not attempt to enter. To my present purpose this particular feature in the above case, namely, the production of vegetations, appears to me less important than the inflammatory affection that immediately preceded it. Was this affection a manifestation of the general syphilis from which the patient was presumed to be suffering? or was it merely an intercurrent affection?

That my patient had syphilis does not, it seems to me, admit of a doubt. Furthermore, the character and distribution of the lesions would indicate a syphilis of not long standing. Whether the first eruptions observed by Dr. Fischer were syphilitic or not, it is difficult to say. A

[2] Vierteljahrssch. f. Derm. u. Syph., 1886, p. 157.

healthy child, two years of age, affords pretty good presumptive evidence that the disease was contracted at least not much over two years ago, corroborating the evidence of the local lesions. But, on the other hand, none of the symptoms presented by the patient when he was first seen by me, could be regarded as having any of the ordinary characters of syphilitic manifestations, unless it be the condition of the finger-nails, and even this might be taken for a keratosis due to some other than a specific cause. The inflammatory lesions of the head, hands, and feet were primarily erythematous, but with that polymorphous character which is expressed in the term *erythanthema*, as first employed by Auspitz. Erythanthema is a form of cutaneous eruption of which the fundamental condition or form of activity is an erythema, which, in its subsequent course, may be modified by a great variety of local efflorescences—vesicles, pustules, papules, wheals, or other so-called primary lesions. It embraces, but is a little more comprehensive than, the *erythema multiforme* of Hebra. It may be incidental to, or symptomatic of, various morbid conditions. When not obviously symptomatic of any clearly recognized systemic disease, it is called "idiopathic" or "essential," rather, it must be confessed, for the sake of convenience than with a view to absolute scientific precision. Sometimes the eruption is the expression of a general toxic condition, or again of a local nerve (neuritic) disturbance. May such an exanthem be a result of syphilis, and if so, in what sense? Is it a direct manifestation of the disease, in the same manner as are the commonly recognized syphilodermata, or is it only a secondary, an incidental and accidental effect of the syphilis?

That the erythanthema (for so I would characterize it) in G——'s case was in some manner due to the syphilis may, I think, be inferred from the fact that it was so intimately associated with an outbreak of manifestations which were undoubtedly syphilitic in character; and not only was it directly followed by such manifestations, but the preliminary erythematous exanthem was succeeded *in situ* by lesions which were pretty distinctly syphilitic. The vegetations upon the face and neck, except as they simulated (especially in the latter situation) condylomata lata, may have expressed only certain peculiarities in the nature of the irritation, or that of the tissues affected. But the fact that the erythanthema was followed by a general eruption of miliary and lenticular papules over the body, the occurrence of circumscribed coppery infiltrations in the erythematous patches themselves, together with the rapid way in which these later lesions, as well as the vegetations, yielded to the topical and internal use of mercurials, renders it to my mind extremely probable that between the preliminary erythanthema and the syphilis there was a definite etiological connection.

Moreover, the existence of such a connection gathers probability in view of certain other cases that may be cited. With some hesitation I refer, first of all, to the case of the syphilitic roseola. The precise etiological position of this exanthem has never been fully determined; whether it is of the same nature as the succeeding syphilides, or is merely an expression of reflex sympathetic irritation, and more nearly related to certain of the toxic exanthems. To be sure, in certain of the efflorescences granulation-cells have been found effused along the blood-vessels, but, if I mistake not, it was particularly in those lesions known as papulo-erythematous. At all events, this eruption differs entirely in its course and general characters from the papular syphilides which follow it. As in the case of the erythanthema above described, the erythematous or roseolous lesions may gradually be transformed into well-marked infiltrations, the erythematous efflorescences turning into syphilitic papules.

It is stated by Hebra that a universal erythema papulatum may occur as *prodromal exanthem* of *syphilis bullosa* and *ulcerosa*. Neumann reports the case of a man[1] whose back was covered with groups of syphilitic papules, who at the same time had repeated attacks of *erythema* iris of the palm. He had also observed erythema iris occur as the initial stage of syphilitic pemphigus neonatorum. The coincidence of erythema with syphilis had also been remarked by Danielssen and Lipp. According to Lipp, those cases of erythema that occurred in connection with syphilis were especially severe or long continued. Again, in hereditary syphilis it is not uncommon to see patches of erythema precede the eruption of frank characteristic efflorescences of syphilis. To this preliminary eruption the French have given the name *érythème précurseur*. In the palms and soles the eruption often consists of a diffuse, coppery redness, which is followed by desquamation in lamellæ, not unlike what occurred in G——'s case.

Mauriac has described, under the name *érythème noueux syphilitique*, certain eruptions occurring at an early stage of syphilis, of a circumscribed erythematous character, differing totally in their clinical appearance from the commonly recognized forms of syphilitic exanthemata, and bearing the closest resemblance to *erythema nodosum*. They are attended with localized pain, and occupy the usual seats of the disease they simulate. The frequency with which he has met with this form of eruption in syphilitic patients, and the fact that in the course of their resolution the efflorescences often form movable, subcutaneous tumors detached from the skin—as indicating a gumma-like infiltration undergoing resorption—are the reasons for Mauriac's regarding these affections as true products of syphilis. The same authority also describes subcutaneous infiltrated plaques, nodosities, and tumors of an indolent character, some of which after a time show fluctuation and then undergo resorption; others go on to rapid suppuration and ulcerate, and of these latter some show a markedly intractable and malignant character.[2]

Within the past eighteen months I have met with three cases of what might be termed syphilitic erythema nodosum, and with one of them were associated the characters of the malignant form described by Mauriac.

The first case was that of Henry G——, a young man twenty years of age, of delicate build and appearance, who entered Charity Hospital, April 12, 1886, with an indurated sore on the penis, a maculo-papular syphilide on the body, and angina. About a month later, in connection with a pustulo-crustaceous eruption of the face, and a papulo-pustular syphilide on the body, the patient began to complain of severe pain and swelling in the right foot. Later the swelling and pain disappeared from the foot and reappeared in the knee. These swellings, it is recorded, would often appear and completely disappear within an hour. On June 24th two or three deep-seated infiltrated nodules were observed on the outside of the legs, near the head of the fibula. They were about the size of filberts, of a rather bright red color, and, in general appearance, were not unlike the lesions of *erythema nodosum*. A few days later similar lesions began to appear in other situations on the lower extremities; two on the outer side of the right thigh, at about its middle; two on the left thigh, just behind the trochanter major; one at the middle and outer side of the left leg; one behind the right trochanter, and one just below the lower third and over the crest of the left tibia. These lesions were attended with but little pain. A few days after, and before the lesions had disappeared, the patient left the hospital.

The second case, Mary H——, aged twenty-three, was

admitted to Charity Hospital April 19, 1886. She had previously been an inmate a year before with chancre, followed by secondary syphilis. At the time of the last admission she had a papular syphilitic eruption, chiefly upon the face, and complained of much pain in the clavicles, sternum, and tibiæ, mostly at night. These pains continued severe in spite of treatment, and in June became very distressing, especially in the legs. The patient was anæmic and cachectic looking. An ulcerating lesion appeared upon the palpebral conjunctiva of the left eye, attended with considerable conjunctivitis. There appeared about this time two red, circumscribed swellings on the outer aspect of the left leg, just above the malleolus, which were exquisitely sensitive to the touch and the seat of intense pain, commencing in the latter part of the day and continuing a good portion of the night. They were not connected with the bone, but evidently involved the skin and subcutaneous tissue. The largest occupied about the area of an English walnut; the other was perhaps half as large. They did not disappear readily under treatment, either by mercurials or by the iodide of potassium, but continued for a fortnight or more, and then rather suddenly subsided, together with the pain. The latter, however, returned again, and was only relieved by rapidly passing a Paquelin cautery over the affected surface.

The third case was that of a female patient, fifty-two years of age, Minna S——, who came to me at the Polyclinic. I saw her first in November, 1885. She then had a universal, very abundant syphilide, made up of large lenticular papules. There was also some angina. The case was evidently a recent one. As to the origin and inception of the disease little could be learned. An examination of the genitals was not consented to. The patient stated that she had first noticed an eruption the month previous, when she applied to her family physician, who prescribed mercury. She was married, and the mother of several healthy children, but has borne none for a number of years. The husband was not examined. The patient's general condition was considerably affected by the disease, which had the marks of a severe type. The eruption, however, yielded pretty readily to mercurial inunctions. Later, deep ulcerations made their appearance low down in the fauces, on either side, but healed after thorough cauterization with nitric acid. Three or four months after the first visit the patient came complaining of very severe pains in the legs. On pushing down her stockings an eruption was displayed that at a glance could not be distinguished from the most typical *erythema nodosum*. In all there were five or six nodes; one large one (about the size of an English walnut) on the outer side, and at about the middle of the right leg; another just opposite, and one lower down on the inner side. On the left leg there was one at the lower third, on the outer and posterior aspect, and another prominent one on the inside, just back of the tibia. In size they varied from that of an English walnut to that of a filbert, were considerably elevated above the *niveau*, softish to the touch, and toward their centres of a violaceous hue, with deep-red color outside. Except for the unusual degree of pain and the very exquisite tenderness, the diagnosis *erythema nodosum* would doubtless have been made without hesitation. They proved rebellious to treatment, and remained stationary for about a fortnight, during which time the pains were distressing. Meantime a certain alteration in appearance was noted in one or two of the lesions. The centres became paler, of an ashy hue, as though ischæmic. No distinct fluctuation could be felt, but the extreme tenderness prevented thorough palpation. After a time ulceration took place, and deep, excavated, sinuous sores were produced, which were a month or two in healing. When last seen (July 10th) the patient was in a fair state of health, all manifestations of the disease having disappeared, excepting a slight ulcer, which had recently broken out again in the cicatrix of one of the old sores.

These cases of erythema nodosum, together with the other erythematoid eruptions previously referred to, serve to show that various forms of erythanthema may be associated with syphilis in such a manner as to imply some sort of etiological connection. Certain peculiar modifications in their form or clinical course usually distinguish them more or less from the corresponding simple eruptions, and this, together with the fact that they often coincide in their appearance with, or are closely followed by, manifestations that are unquestionably syphilitic, would indicate that they and these latter manifestations are both due to syphilis as a common cause. Admitting then, as I think we may, that between the syphilis and the symptoms we are discussing, the relation of cause and effect does exist, that it is not merely a case of accidental coincidence, are we justified in regarding these irregular manifestations as symptoms of syphilis in the same sense as the regular and more typical syphilodermata? But first we should define what is meant by "syphilodermata."

Loosely speaking, a syphiloderm, a cutaneous syphilide, may be defined as any cutaneous affection due to syphilis; but in a stricter, and, as I think, more proper sense, as well as in the very common acceptation of the term, it is a cutaneous affection which is pathognomonic of syphilis; an affection which only syphilis can produce. It is characterized, I believe, in every case by a peculiar modification of structure, and a special course of evolution and involution. Everywhere in all the specific eruptions we have neoplastic growth, a growth of the nature of the granulomata, in which the cells have but a brief life history, and their early decay is the cause of the varying phases in the course of each efflorescence which constitute one of its chief characteristics. From the initial lesion to the gummata the prime features in the pathology are essentially the same: a local focus of irritation attended with the production of granulation-cells destined to rapid decay. As the type of all syphilodermata, may be taken that commonest form which is intermediate between the initial sclerosis and the gumma, to wit, the syphilitic papule. Whatever has not the essential character of the papule is not, strictly speaking, a syphilide. In a word, the cardinal feature of all syphilodermata is the specific infiltration. Upon the amount and distribution of this infiltration, the rapidity of its development and involution, and the degree and phases of the inflammatory reaction that attends it, depend all the multitudinous forms that syphilodermata may assume.

But, as is well known, many cutaneous or other symptoms arise in the course of, and are in one way or another due to, syphilis, which cannot be included in the category of infiltrations. Some of these are almost constant and more or less characteristic, others are merely occasional and accidental. In some the etiology is obscure. Thus the so-called *pigmentary syphilide* (a term to which, however, I would take exception) may be sequellar to an antecedent roseolar or papular syphilide, or it may be the expression of some remote sympathetic irritation, perhaps in a manner analogous to that of the common cloasmata. In any event, it would scarcely be regarded in the same sense a direct manifestation of the disease as is the syphilitic papular exanthem. Again, the purpura which sometimes occurs in syphilitic patients, either in a simple form or as a hemorrhagic complication of a specific eruption, is a symptom in nowise pathognomonic, but is probably due to cachectic, toxic, or neurotic conditions, which may be incidental to the specific disease, but are not peculiar to it. Similarly with regard to the pallor that many syphilitic patients exhibit.

But we may go a step further in limiting the definition of the true syphilide. Wherever syphilitic infiltrations occur there is good reason to believe that at that point an accumulation of the *materies morbi* takes place. It is the lesions of the disease that most readily convey the contagion. Though the serum of the blood without doubt contains inoculable germs, and is capable of com-

municating the disease when brought in contact with surfaces denuded of their integument, it is in a less degree contagious than the secretions of a syphilitic efflorescence such as the initial sore, a mucous patch, or the matter from a syphilitic pustule, or ulcer. Thence the inference may be drawn that the common syphilodermata are the expression of a determination of the syphilitic virus to the surface, where they constitute in a degree isolated foci of the disease. What the cause of this determination to the surface may be is not known. It may be vaguely referred to an effort on the part of nature at elimination. That it is due to something more than a gradual process of filtration through the skin is evident from the intermittences in the occurrence of cutaneous symptoms, as well as from the arbitrary forms in which the efflorescences are distributed and arranged. This arrangement and distribution betoken a central, probably nervous, controlling influence, but more than that can only be conjecture.

Now, in the case of the affection or affections which I have ventured to group together under the term *erythanthema syphiliticum*, have we to do with irritative processes which are the direct effect of a determination of the *materies morbi* to the surface, the same as in the case of the common or true syphilodermata, or do they represent rather indirect and secondary effects of the disease, and so correspond in their mode of origin to the simple affections which they resemble? On the one hand, it is not difficult to conceive that a sudden elimination of the disease-poison through the skin might produce a dermatitis in the same way as the sudden elimination of mercury through the salivary glands gives rise to ptyalism, or as the escape of iodine or bromine through the sebaceous glands is supposed to produce an acne. Furthermore, the fact that the erythematous lesion may subsequently become the site of well-marked syphilitic infiltration (as in G——'s case, and possibly in the last-cited case of erythema nodosum), gives a certain plausibility to this view. The dermatitis then becomes the immediate, the subsequent cell-development the gradual, effect of one and the same cause. They are two phases only of one process.

But, on the other hand, is it not at least equally supposable that, during those periods of activity in syphilis which are ordinarily attended with specific manifestations upon the skin, there may arise a condition of general angioneurosis, or localized neuritic conditions, capable of provoking irritative eruptions upon the skin, which have no connection whatever with any process of cutaneous elimination? Nor does the fact that erythanthema may be followed by a true syphilitic infiltration *in situ* necessarily militate against this latter hypothesis. There are circumstances in the clinical history of syphilis that tend to show that a topical irritation in a syphilitic subject is capable of evoking a true syphilitic lesion. So far as traumatic irritation is concerned, the fact is well attested. It is well known that a traumatism, especially when there is protracted irritation, is liable in a syphilitic person to become the seat of a local syphilitic process. This fact was particularly demonstrated in the experiments of Tarnowsky.

It is true with regard to most pathological processes in the skin, such as eczema, acne, psoriasis, and the like, that when the subjects of them become syphilitic these processes are not necessarily, nor even commonly, modified materially by the syphilis. Their lesions do not necessarily become infiltrated. In fact, it often seems as though the pre-existent pathological process, having once preoccupied the ground at the affected points, monopolized it to the exclusion of any syphilitic or other extraneous process. With regard to many eruptions I believe this to be true. Eczema, so far as I know, is never modified by syphilis, except through the cachexia induced by the disease, which usually renders all intercurrent affections somewhat severer than they otherwise would be. That it may coexist as a complication with an irritated or inveterate syphilitic lesion is observed often enough, but the eczema always preserves its characters distinct, nor does it ever, as I believe, elicit a syphilitic infiltration. Whether acne efflorescences are especially liable to become the seats of specific lesions I am unable to answer. From my own experience I should say that syphilitic patients, with acne vulgaris, are little if any more liable to syphilodermata in the face than others. It is doubtful, again, if anyone ever saw the lesions of an iodine acne become infiltrated in a syphilitic subject. With regard to psoriasis opinions upon the point under consideration have long differed, some maintaining that it may be modified by syphilis, others that it is not. It is doubtless much more likely, in psoriatic patients who contract syphilis, that the syphilitic lesions should assume a psoriatic character during this period of desquamation, than for the pre-existent patches of psoriasis to become the seats of specific infiltration. Nevertheless, that the latter may sometimes actually be the case, appears from a case recently reported by Dornig,[1] in which groups of syphilitic papules corresponded exactly with the sites of lesions of psoriasis which had long preceded the occurrence of the syphilis. The psoriatic lesions were gradually transformed into syphilitic lesions. This one case, it seems to me, suffices to show that it is possible for a common pathological process to act as the exciting cause of a syphilitic infiltration in the same manner, if not to the same degree, as do traumatic processes. That the former act in this way only exceptionally must, I think, be admitted. It might accordingly be inferred that the syphilitic erythanthema would only rarely produce a true syphiloderm. But this is not certain. An exanthem that develops during the active stage of syphilis, or during one of its periods of recrudescence, and is, moreover, a more or less direct consequence of the syphilis, would be far more likely to be attended with a syphilitic process at the affected point than would an affection, wholly independent of the syphilis, that may occur in the intervals of exacerbation, or, indeed, may have been antecedent to the specific disease, and has, perhaps, impressed its own peculiar character upon the tissue affected, so as to render it in a measure insusceptible to any other modification.

From the above considerations I draw the following inferences:

First.—That certain forms of erythanthema arising in the course of syphilis may be regarded as products of the latter disease; more especially when they coincide with, or are directly followed by, an outbreak of typical syphilitic manifestations.

Second.—That in view of their resemblance to simple angioneurotic or neuritic affections of the skin, it is probable that they also correspond to the latter in their mode of origin; and, while doubtless due primarily to the syphilis, they are not pathognomonic of the latter disease, and probably not equivalent etiologically to true syphilodermata.

Third.—And, finally, that the syphilitic erythanthema may, through reflex irritation, and in the same manner as a local traumatism, become the seat of a characteristic syphilitic infiltration.

An Error in Diagnosis.—The following is vouched for by an exchange as an actual occurrence: "A young man, fresh from college, was sent by his father, an old practitioner, to attend a case of labor. On making an examination he found the os undilated. After waiting an hour he applied belladonna ointment and endeavored to make forcible dilatation. Another hour passed, but no dilatation. Being alarmed he went for his father, but before they returned the child was born. The father found the child's anus red and patulous, and besmeared with belladonna ointment. The young man had met with a breech presentation, and had mistaken the child's anus for an undilated os uteri."

THE ELECTRIC LIGHT AS AN ILLUMINATOR —THE EFFECT OF STRONG LIGHT ON THE EYE.[1]

By J. ALFRED ANDREWS, M.D.,

OPHTHALMIC SURGEON TO CHARITY HOSPITAL, NEW YORK, ETC.

THAT the exposure of the eye to an excess of light may be attended with harmful effect is a fact attested by the cases recorded in ophthalmic literature; and this subject has assumed a fresh practical importance since the application of electricity to lighting purposes.

Mackenzie, Jäger, Arlt, Dufour, Haab, Emmert, Sulzer, Simeon Snell, and others have recorded cases in which either retinitis or scotoma, or other visual disturbances, have resulted from exposure of the eyes to bright light.

Among 12 cases reported by Jäger as having resulted from looking at an eclipse, 8 cases were without material change; in 4 cases there was choroiditis.

Arlt describes one case of chronic choroiditis produced by looking at the eclipse of July 28, 1851.[2]

Schirmer gives one case of positive central scotoma after blinding of retina by lamplight, the same having occurred before when the patient looked at the sun or glaring light. Ophthalmoscopic examination showed an "especially dark macula lutea;" otherwise the fundus was normal.[3]

Dufour[4] gives one case, evidently carefully observed. The whole macula lutea was taken up with a dark-brown pigmented spot, the centre of which formed a sharply defined yellowish-white patch. Vision was reduced to $\frac{1}{30}$ during twenty-two days; the macula region was wholly normal. Vision was improved to $\frac{1}{2}$.

Haab[5] relates one case of central scotoma produced by observing the eclipse of the sun.

Emmert[6] gives one case. Vision reduced to $\frac{2}{3}\frac{0}{0}$; fundus normal.

Simeon Snell (*Ophthalmic Review*, May, 1883, p. 141) records one case of retinitis, caused in a girl, aged twenty, by a "single flash from a sun reflector," in the hands of a boy. The eye was affected immediately; on the next day vision was = Jäger 20. In the neighborhood of the macula and optic disc there was cloudiness of retina. Perfect recovery.

D. Sulzer (*Klin. Monatsbl. f. Augenheilk.*, April, 1883, p. 129) relates four cases of retinal affection from direct observation of the eclipse of the sun of May 16, 1882. The symptoms were central scotoma, slight hyperæmia of the optic disc, exudative condition of the yellow spot, which, in one case, led to pigment degeneration in the region of the yellow spot.

H. R. Swanzy (*Ophthalmic Review*, May, 1883, p. 142) gives two cases of central amblyopia from exposure of the eye to the direct rays of the sun. There was in each case positive central scotoma, and metamorphosia, and a positive flickering after-image, which latter symptom continued four months after the exposure. There was no visible change in fundus. Vision (previously normal) was $\frac{6}{9}$ in right eye. Read with slightly excentric fixation with right eye, owing to central scotoma, although examination in the usual way for central scotoma, either with blackboard or perimeter, gave a negative result, the conclusion being that the defect was extremely small. But the patient declared that he saw Snellen's smallest type with difficulty, owing to the black spot which came just over the word he wished to look at. These cases are also interesting as having occurred in two individuals —a coachman and his employer—from the same cause at the same time.

Deutschmann (*Von Graefe's Archiv*, vol. xxviii., 1883, p. 241) records four cases of damage to the eye, caused by watching the eclipse of the sun on May 17th, 1882. Three of the patients had gazed at the sun with the naked eye; in the fourth case, a dark-blue glass had been used. Every one of the four had noticed, immediately after gazing at the sun, a dark or semi-blind patch in the middle of the field of vision, and in each a small positive scotoma was found on examination; scotoma not absolute in any of the cases. Gradual improvement occurred in all, but absolutely perfect vision was not recovered in any case. The ophthalmoscope showed corresponding changes in all, viz.: in the cases seen early, a small, bright-white spot at the centre of the macula lutea, and around this a blood-red ring shading off into the normal color; in the older case (four months), an appearance less easily distinguishable from that of the normal eye, and similar to that which the other cases presented when recovery was nearly complete.

Under the caption "Neuroses of the Visual Nerve-apparatus, caused by the Continuous Action of Bright Light," Mr. Reich (*Von Graefe's Archiv*, vol. xxvi., 1880, p. 135) described an epidemic of snow-blindness which occurred among a body of laborers engaged in clearing a way through masses of snow which obstructed the road between Passawaur and Mrleti, in the Caucasus. The rays of the sun, reflected from the vast stretches of snow on every side, produced an intense glare of light, which the unaccustomed eye could not support without the protection of dark glasses. A few of the sturdiest among the laborers were able to work with impunity, but the majority, and especially the weakly and anæmic, suffered severely in their eyes, in spite of various devices to protect them from the light. Among 70 strongly marked cases, 30 were so severe that the men were absolutely unable to continue their work or to find their way home. They were collected in a covered place, where Reich found them, on his arrival, prone on their faces, striving to hide their eyes from the light, and crying out from pain. Photophobia was present in all the cases. Hyperæmia of the conjunctiva, with more or less injection of the ciliary vessels, and even chemosis, was found in all the severe cases; those with chemosis complaining the most of pain. Cornea not affected in any case. The pain, generally of a cutting character, did not cease in darkness. Strong *contraction* of the *pupils* in all cases, except two, in which they were *dilated*, and in these two cases there seemed to be some degree of retinal anæsthesia and contraction of the visual field; the ophthalmoscope showed capillary hyperæmia of the optic discs and some over-fulness of the retinal arteries and veins; ciliary injection and chemosis were present in both cases, and the eyeball tension appeared to be somewhat increased. Recovery was gradual, but complete, in all cases. The author declared that the impairment of vision was not of the nature either of hemeralopia or nyctalopia, meaning by the latter the condition in which vision is persistently defective in ordinary light, but improved in diminished light. The conjunctival hyperæmia, which played a very unimportant part in the affection, is referred by the author to reflex dilatation of vessels through the action of light. W. C. Rockliffe (*Ophthalmic Review*, September, 1882, p. 308) records a case of acute conjunctivitis which he referred to the action of the *electric light*, the patient having been engaged in adjusting the carbon points of a Siemen's electric lamp of *three-thousand-candle power*, which he did without colored spectacles. The patient had noticed on other occasions that, on descending the ladder, after adjusting the carbon points, and a short expose, in close proximity to this very intense light, that he was unable to perceive the people on the street, but that this effect soon passed off. On a particular occasion, as his power of vision returned (in about fifteen minutes), there followed a rapidly increasing lachrymation, photophobia, pain, and swelling of the lids, the whole of these symptoms having been developed

in thirty minutes. Rockliffe describes the lids of both eyes as having been very hot, red, swollen, and brawny, and as being on a level with the superciliary ridge, the swelling extending some distance below the brow. The pain was most acute in and around the eye. The conjunctival vessels were exceedingly large, and the eyelids and the eyeballs were a brilliant scarlet. The cornea were clear. All of these symptoms yielded to a brisk purge and a lead lotion in forty-eight hours. His fellow-workman was similarly affected, but to a less degree.

A. Emrys-Jones (*Ophthalmic Review*, April, 1883, p. 106) records the case of a person engaged in experimental work with the arc electric light, which necessitated his gazing intently with the naked eye at the LIGHT, from a distance of a *few inches*. As there was no inconvenience at the time, and that the longer he looked the more accustomed his eye became to the light, he continued his observations for *twenty minutes*. The next morning he awoke with intense pain in the eyes, and profuse lachrymation and photophobia; also slight redness of the conjunctiva, but no swelling of the eyelids. A drop of atropine instilled into the eyes gave instant relief, and as soon as the physiological effects of the atropine had passed off the patient was able to resume his work. Jones also adds a description, written by the patient himself, who had a great deal to do with electric lighting, in which he speaks of the effect of the light on the eyes of persons engaged in working in close proximity to the light (*arc light*). In the worst cases, which generally arise from adjusting the lamp (*two-thousand-candle power*) while burning, without goggles or smoked glass, the distance of the eyes would average eighteen to twenty-four inches, and with weak eyes *one minute* will produce certain inflammation (?). He thinks that much depends on the nature of the light, as he found that either an excess of current, which produces a violet light, or a defect of current, which gives an orange light, is less injurious than the normal (white, tinged with a sky-blue) light. David Little (*Ophthalmic Review*, July, 1883, p. 197) speaks of a case of retinitis occurring in a gentleman, engaged in scientific experiments with the electric light, who had neglected, on one occasion, to put on his dark spectacles while thus operating; the box containing the electric light was suddenly opened, and the light fell upon his *right* eye. It was a great shock to him, and he was blinded for several minutes; his eyes were very intolerant of light for several days afterward, and he suffered a great deal from headache. Two months after the accident he consulted Dr. Little on account of a mist and dark specks before his *right* eye, which had existed since the accident. Vision of right eye = $\frac{20}{50}$; the vision of left eye was good, and the fundus was normal. There was haziness over the right optic disk and the retina immediately around it.

Eye-affections caused by lightning have been classed in the same category with those ocular disturbances caused by exposure of the eye to strong light, partly, perhaps, because in the older text-books the intense light of lightning was assumed to be the chief agent; but the intensity and duration of lightning are not sufficient, and the lesion so produced does not at all correspond with that produced by lightning, since the scotoma produced by exposure to bright light, as recorded in literature, has been of limited extent, instead of affecting the entire field as in the case of lightning. Moreover, it is impossible to ascribe to the action of light the associated nerve-lesions, or the structural changes in the choroid and lens, which obviously are caused by lightning. That light, under certain conditions, is capable of producing opacification of the crystalline lens—one of the prominent ocular lesions caused by lightning—has been demonstrated by Czerny, who showed that the direct rays of the sun, condensed by a lens, will produce in the eye of the rabbit an opacity of the crystalline lens in about a quarter of a minute, by coagulation of albumen; but this can hardly afford an adequate explanation of the production of cataract by lightning, for, apart from the less intense brilliancy of a lightning-flash as compared with concentrated sunlight, the duration of the former is much less than a quarter of a minute. Leber (*Von Graefe's Archiv*, vol. xxviii., p. 255), who has given a comprehensive analysis of all that is at present known of ocular injuries caused by lightning, rejects the idea of any mechanical production of the opacification of the lens, and attributes it to a "direct *physico-chemical action* of the electricity on the lens substance by which its albumen is coagulated;" but Leber does not refer this coagulation to heat alone, for it can readily be shown that a higher and more enduring degree of heat would be required than can reach the lens during the lightning-flash, nor was there any external sign of scorching of the eyes in those cases in which cataract was produced by lightning; hence Leber regards the coagulation of albumen to be a kind of catalytic action, as compared with the curdling of milk which occurs during a thunder-storm. Leber further suggests that this catalytic action is not confined to the lens, but would probably be discoverable as an opacity in many other structures, were they transparent. The opacity of the lens in these cases is said to be permanent, and the non-vascularity of the lens may furnish an adequate explanation of the permanence of the lesion in this body. This is certainly a reasonable hypothesis, but it does not necessarily exclude the probability of a mechanical injury to the lens, simply because the capsule of this body remains undisturbed, any more than the rupture of the choroid, and hemorrhage from the choroid and retina, and partial detachment of the retina, which are also known to occur from the shock without the patient being struck by the lightning, and without rupture of the external tissues. Thus we see intense light is not the chief agent in an electrical explosion in producing the eye-affliction.

There is another class of cases which may be considered in connection with this subject, viz., the opacity of the lens occurring among glass blowers, in whom the intense radiant heat to which their faces are exposed (148° Fahrenheit) seems to be the chief agent in producing this condition; but I have not found cataract so common among the glass-blowers whom I have examined—284 in all—4.5 per cent. showing lenticular opacities among 65 men under thirty-eight years of age, and twenty per cent. among those men who were over forty years of age. Meyhoffer (*Klin. Monatsblätter f. Augenheilk.*, February, 1886, p. 49) found among 506 glass-blowers just the double of my percentage among those men under forty years of age. I did not find any lesion of the fundus of the eye which could be referred to the occupation as a cause.

In the first class of cases of eye trouble alluded to above, as resulting from exposure of the eyes to direct sunlight, it appears that lesions are produced which are identical to those found by Deutschmann in the retina of rabbits when the direct rays of the sun, condensed by a concave mirror, and then rendered parallel by a convex lens, are caused to enter the dilated pupil. After exposure for only a few seconds the ophthalmoscope revealed a silvery-white patch surrounded by a dark-brown ring in the retina. The microscope showed that the material changes consisted in an actual disorganization of a limited area of the retina by coagulation of the albumen in its tissue, and beneath and around this a vascular reaction in the choroid, leading to hyperæmia, exudation, diapedesis of blood-corpuscles, and pigment disturbance. It will be observed by referring to the cases recorded by Arlt, Schirmer, Dufour, Haab, Emmert, and others, of visual disturbance caused by exposure of the eye to direct sunlight, that in the majority of instances there was no demonstrable lesion in the fundus oculi; nor is the evidence as to the causation quite satisfactory when such lesions have been found, the pre-existence of the lesion in the fundus not having been disproved; and yet the

similarity between the effects obtained by Deutschmann in his experiments (cited above) on rabbits and those observed in the human eye is presumptive evidence that the actual lesion in the latter case is also a destructive coagulation of albumen in a minute area of the fovea centralis, together with congestive or inflammatory changes beneath and around this spot, although the condensation of the light in the case of Deutschmann's rabbits and the dilatation of their pupils constitute an important difference in the conditions.

In order to ascertain whether the invisible heat-rays were concerned in producing the changes in the fundus found in the rabbit under exposure to direct sunlight, Deutschmann caused the pencil of light to pass through a stratum of water two decimeters thick before reaching the eye. The same effect as before was obtained, but required rather longer for their production; but, of course, the mere exclusion of the obscure heat-rays does not exclude *heat* as the essential cause of the mischief, for it can readily be shown that in the mixed radiation from a luminous object the light is capable of being converted into heat; therefore, that the light-rays also raise the temperature. The use of dark glass in Deutschmann's cases did not suffice to prevent the damage to the retina.

The spectroscope declares that the solar, gas-flame, and electric-light spectra have for their base a continuous strip or band of light—in the case of the gas-flame (the bright part) crossed by the sodium lines only; in that of the sun, by Fraunhofer dark lines; and of the electric (arc) light, by the bright line of carbon. The illuminating power of each of these sources of light is thus shown to be due to the incandescence of their several solid and gaseous constituents.

It is of practical importance to learn something about the relative effect of the different forms of artificial light on the human retina. All forms of artificial light contain, as compared with daylight, an excess of waves of long wave-length, *i.e.*, they are of a *yellowish* hue. In the electric light the short-wave rays predominate, *i.e.*, the violet rays. The ultra-violet region in the light of the electric arc is from six to eight times as long as the whole of the visible part of the spectrum.

Even the electric light looks yellow as compared with daylight, which latter, although generally called *white*, has been shown to be decidedly *bluish*; but, as far as mere *color* is concerned, the *electric light* approaches nearer to that of the *sun* than does the gas or lamp flame. But which has the more to do in producing evil effects on the eye after long and continuous work by artificial light—*color* or *heat?* Meyer gives the following proportionate constitution for three kinds of artificial light:

	Red.	Green.	Blue.	Violet.
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Gas emits the greatest amount of heat; petroleum lies between gas and the electric light, which latter, from the fact that there are no gaseous products to radiate heat without light, taken together with the high temperature of the incandescent carbon, unite to give us the maximum of light with the minimum of heat. Those who have a great deal to do with the *arc electric light*, which is intensely brilliant, say that the injurious effect on the eye depends a great deal on the nature of the light, *i.e.*, a violet light, produced by an excess of current, or an orange light, given by a defect of current, is less injurious than the normal light—white, tinged with ashy blue—and that a fluctuating light is always more dangerous than a steady one.

Tyndall has shown that the value of the luminous radiation from the flame of oil, gas, and the electric light is as follows:

	Luminous.	Obscure.
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]

We have, therefore, with the *electric light*, the *maximum of light* with the *minimum of heat*. We have seen that in the electric light the short-wave rays predominate, *i.e.*, the *violet rays*, and that the *ultra-violet* region in the electric arc is from six to eight times as long as the whole of the visible part of the spectrum. We know that chemical action is more energetic in this part of the spectrum than in any other part, and that this action extends beyond the violet to the *ultra-violet rays*, and the properties of this part of the spectrum are very strikingly shown by the pronounced action exerted by the electric light in the growth of plant life.

Chardonnet (Vision des radiations ultra-violettes, Compt. Rend. hebd. des séances de l'Acad., No. 8) has recently made some interesting investigations on the absorption of ultra-violet rays by the media of the eye, particularly by the crystalline lens, this absorption not being done without fatiguing the eye, especially when it concerns the long and brilliant spectrum of the *electric arc*. But he found, on photographing the spectrum of the incandescent electric light, that the spectrum hardly passed beyond the visible spectrum; hence he inferred that this incandescent electric light saved the media before the retina the labor of absorbing and diffusing the ultra-violet spectra. I do not believe that we should attach much practical importance to this explanation. It is easy to convince one's self that the inconstant and unsteady intense glare of the *arc electric light*, only faintly modified by an *opal* or *ground-glass globe*, is extremely distressing to the eyes.

So far all the cases of injury to the eye from the electric light recorded in medical literature have resulted from exposure of the eye in close proximity to the *arc electric light*, and this has, in every instance, been of a very intense brilliancy, generally that used for street illuminating purposes—two-thousand-candle power—which may be actually fifteen-hundred-candle power. In many of these cases a pre-existent abnormal condition of the eye was not excluded; and if we compare the groups of cases so far recorded, the evidence seems to me to point more directly to a vaso-motor disturbance—*i.e.*, that we can best account for the condition by invocation of the sympathetic nervous system, rather than by assuming an actual mechanical or chemical injury. The severe pain and photophobia complained of would certainly be explained by the excessive stimulation of the whole retina, and, corresponding thereto, a general hyperæmia of the uveal tract; and these causes might naturally augment any pre-existing retinal or choroidal affection. At any rate, with regard to retinal changes it is not by any means established that simple dazzling by bright light can produce a progressive diffuse retinitis, such as has been claimed it has. However, the case of the late Professor of Physics at the University of Ghent, J. Plateau, who, in 1829, while trying to observe the effect of irritation of the retina, gazed steadily at the sun for twenty seconds, chronic irido-choroiditis having resulted (?), followed by total blindness in the course of fourteen years, is on record.

So far as I have been able to ascertain, no case of accident to the eye has been reported as having been caused by the *incandescent electric light*. Of the 1,100 persons whom I have examined and observed during the past year who work by day or by night for many hours by the *incandescent electric light* of *Edison's lamp*, there was not a single instance of injury to the eye; but, on the contrary, I was surprised to find that a considerable number of these persons, with a high degree of myopia and choroidal changes, were absolutely comfortable while working by this light, and they expressed themselves as having experienced a great improvement in the condition in their eyes since they had begun to work by the electric light (Edison lamp of twelve- to sixteen-candle power), always shaded from the eyes, the light being thrown down upon the work from a short elevation. Many persons among typesetters and copyists have told me that for-

merly, when gas was in use in the establishment in which they worked, they went home from their work with their eyes red, watering, and aching, and this was especially the case among short-sighted persons, but that they could work longer by the Edison light (the arc light distressing them), and without discomfort. Of course, every form of artificial light is more or less dazzling when the source of light casts its image on the retina. We certainly can avoid this dazzling in the gas or petroleum flame by means of an appropriate shade; but, in order to secure the requisite amount of illumination, we must either approach the light close to the head, and thereby expose the eyes to the undesirable radiant heat, or increase the illumination at a greater distance, and thereby make an increased demand upon the vital parts of the atmospheric air in the room, thus vitiating the latter, which is a very undesirable equivalent. The amount of heat radiated by the electric light is very unimportant; and when, after sunlight, we add to its unrivalled qualities as an illuminator the steadiness and absence of combustion from the *incandescent lamp of Edison*—there being, therefore, no consumption or vitiation of the atmospheric air induced by it—together with the practical clinical fact that it is a greater comfort for even persons with existing eye affections to work by this light than by any other artificial illuminator, we must, from a therapeutic point of view, concede to the incandescent electric light advantages not possessed by any other artificial means of illuminating; and anyone who has given the subject thoughtful consideration will at once see the great blessing which would come from introducing this kind of light into our *night-schools*, *theatres*, *public halls*, and those innumerable *counting-rooms* in this great city where large numbers of human beings work by artificial light during the entire day or night, the demand upon the atmospheric air by the individuals alone being, in the absence of adequate means of ventilation, and in the majority of instances very little ventilation at all, in these overcrowded places, terrible enough without the additional mischievous agent in vitiating the atmospheric air present in the many *gas flames*. The advantage of using the incandescent light in our ophthalmoscopic dark-chamber must be evident to every ophthalmic surgeon.

My conclusions are as follows:

The *arc electric light* is not so objectionable on account of its intense brilliancy, which can be modified by means of an opal or ground-glass shade or globe.

The gazing at the *arc lamp* for many seconds is attended with great risk to the eyes. The *arc light*, in its present state, should be positively rejected as unsuitable and actually harmful to the human eye, particularly on account of its unsteadiness.

The *incandescent light of Edison*, because of its steadiness, adequate power and composition, is safe, and occupies at present the first position as a means of artificial illumination. By its use the accommodation of the eye is less taxed than by other illuminators.

The light may advantageously be placed on the table in *front of* the person using it, but it should *never shine directly into the eye*, but always be *completely hidden* from the eyes by means of an opaque shade made of glass or tin, and the light be thrown down upon the work. For obvious reasons, it is further believed that the incandescent electric light is especially beneficial to hypermetropes and myopes.

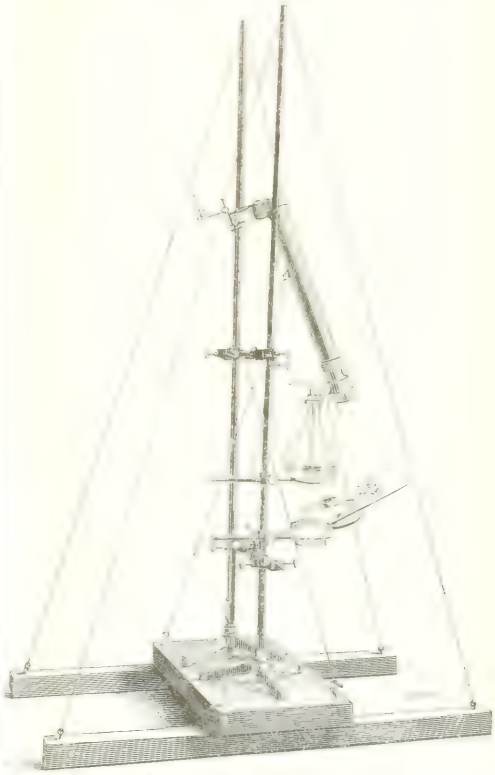
[illegible] West [illegible] Street.

THE GROPINGS OF MEDICINE.—A physician was once conversing with a prince who spoke of medicine as a science of guess-work. "But, sire," he said, "let us suppose that an Egyptian darkness were suddenly to come over the land. Would you not rather trust to a blind man to guide you to Paris than to one who might see in the light; to one who had learned to grope his way in the darkness than to another who would stumble and go astray the moment his clear sight was dimmed?"

A NEW APPARATUS FOR THE [illegible] CAPTIVE [illegible]

BY WILLIAM [illegible], M.D.

SINCE publishing in THE RECORD[1] a preliminary notice of work upon the application of instantaneous photography to the study of the movements of the heart and intestines, I have had constructed a special apparatus which is so great an improvement that it leaves little or nothing to be desired in accuracy and rapidity of movement. The apparatus was devised by Mr. R. D. Gray (the inventor of the ingenious "vest camera" and other photographic improvements) and by myself. I described what was required and suggested various modifications and improvements, but the mechanical details were worked out exclusively by him. To test the rapidity of the camera we photographed a "horse-timer" clock, with a dial marking quarter-seconds, and succeeded in



[illegible] [illegible] [illegible] Mr. [illegible]

taking five distinct photographs in half a second with *one* lens, which has never before been accomplished excepting by Professor Marey,[2] at the College de France, who has taken successive views of flying birds, falling balls, etc., with one lens at a very rapid rate. His camera was unknown to me until after mine was constructed, so that as a success in photography alone the work is interesting.

The camera consists of a circular brass box, 5½ inches in diameter and 1¼ inch deep, containing a circular vulcanite shutter with two apertures, behind which is placed a circular dry plate. Both plate and shutter are revolved in opposite directions to each other by a simple arrange-

[1] [illegible]

[2] M. [illegible]

ment of four cogged wheels moved by a single crank. The box is perforated at one side by a circular opening, 1¾ inch in diameter, from the margin of which projects at a right angle a long brass tube (Fig. 1), which carries the lens. In Fig. 2 the lid of the box has been removed, and the bottom of the box, with the wheels, springs, and partially closed shutter, is presented. The lid is double—that is, it is a flat box in itself. It contains nothing but the dry plate, supported at its centre upon a small brass disk, against which disk it is firmly pressed by a pivot attached to a spring fastened in the lid. The aperture in one side of this double lid, which corresponds with that seen in the floor of the box, may be closed by a slide, so that the lid containing the plate can be removed like an ordinary plate-holder and carried to a dark room, where it is opened and the plate is changed. When the lid is replaced this slide is removed, and as the shutter is made to revolve, the light falls upon whatever portion of the dry plate happens to be opposite the opening.

By reference to Fig. 2 it will be seen that when the large wheel which projects outside of the box is revolved by a crank it turns the small ratchet-wheel, which bears an eccentric pawl. (The crank has been removed in Fig. 2; it is seen in Fig. 1.) The central wheel has only six cogs. The pawl is pressed into one of these cogs by a spring. It pushes the central wheel around one-sixth of its circumference, when it returns to be pressed into the next cog. While the pawl returns it necessarily leaves the central wheel at rest, and whatever momentum this wheel carries is checked by a simple stop pressed by a spring upon the opposite side. The central wheel carries a square axle, which projects through a small hole in the centre of the double lid and fits into the brass disk before alluded to, causing the disk to revolve with the axle. The disk is covered by rubber cloth; and as the dry plate is pressed firmly against the rubber surface by the spring in the lid, the plate adheres to the rubber and revolves with the disk. Thus every complete revolution of the central wheel in the floor of the box carries with it the dry plate, stops it, and moves it on again six times. The velocity of revolution of the plate is only limited by the rapidity with which one can turn the crank.

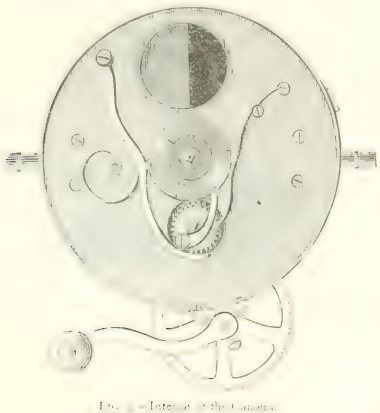


Fig. 2.—Interior of the Camera.

The shutter is revolved in the opposite direction by a wheel whose cogs are seen fitting into those of the little wheel carrying the eccentric pawl.

The two apertures in the shutter are so placed that at the instant of exposure of the plate it is momentarily at rest, while the plate when moving is covered by the shutters. This arrangement prevents vibration of the plate and blurring of the image. The camera is mounted by two lateral axles with screw clamps upon two iron stands, such as are in common use in chemical laboratories. A brass rod attached to the tube steadies it, and allows it to be screwed fast at any angle corresponding to the angle at which the heart is placed. It is thus easy to put a manometer tube in the femoral artery of an animal, bend it up alongside of the exposed heart, and simultaneously photograph the cardiac contraction and the degree of rise of the fluid in the manometer (!). The tube is arranged like the draw-tube of a microscope. It is made long, so as to admit of taking small hearts at life-size. The stand carries a support for the frog or other animal to be experimented upon, and a bottle of physiological salt-solution kept warm by a spirit-lamp beneath.

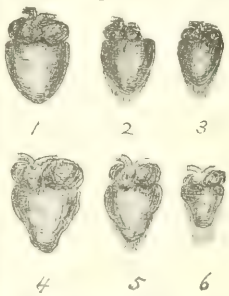

Fig. 3.—Photographs of the Heart in Motion. 1, Normal diastole; auricular systole. 2, ventricular systole. 1, 2, 3 were taken in a half-second; 4, 5, 6, same as 1, 2, 3, after injection of 1 c.c. dose of strophanthus hispidus. 4, 5, 6 were taken in a half second. The pulse rate was 74.

The whole apparatus is readily packed in a small space. I have already taken a number of photographs of various hearts and intestines with it, and the contraction of the heart of the frog produced by *strophanthus hispidus*, the new cardiac stimulant, is seen in Fig. 3, taken by this new instrument. The apparatus has the great advantage that six photographs of a single cardiac pulsation, or of any muscular contraction, may be easily taken in less than one second, or, by simply turning the crank slower, they may be taken at any desired rate to keep pace with the rhythm of the heart. The second-hand of a watch may be placed in the field of view and simultaneously photographed with the heart, so that there can be no question about the series of photographs all belonging to one pulsation.

I have already called attention [1] to the ease with which these photographs are enlarged for lecture-room demonstration, either on paper or in a stereopticon, and the ease with which they may be reproduced in print to illustrate the action of drugs.

25 East Thirtieth Street, New York.

Discussion on Ovariotomy.—The discussion concerning ovariotomy has now been going on for some months. Many of Mr. Lawson Tait's detractors are not slow to suggest that by his eager advocacy of the operation he has induced many surgeons to perform it in unsuitable cases, even if he has not done so himself. Mr. Tait's rejoinder is that he has frequently protested against the indiscriminate removal of the uterine appendages without due consideration. The Liverpool inquiry has not yet come off, and the whole subject may be regarded as in an unsatisfactory state. In evidence of this the following incident recently narrated on good authority may be recounted: A lady coming from abroad was advised to consult a certain distinguished surgeon who diagnosed disease of the uterine appendages and recommended their removal. By the wish of her friends she consulted a well-known gynecologist before consenting to the operation. He carefully examined her and then delivered himself to the following effect: "Yes, you may have your ovaries removed, and may be it will do you good. And you may have your great toe removed, and perhaps that would do you good. Of the two, perhaps the latter will do you the most good." The patient, however, in spite of this opinion visited the first consultant again, had the operation performed, and then left this country.—*London Correspondence.*

Clinical Department.

MIASMATIC HÆMATURIA.

Dr. J. Edward Stubbert, of Bloomfield, N. J., writes: "In the last number of the *Medical and Surgical Reporter* an article appears entitled 'Malarial Hæmaturia.' The writer claims, or intimates, that his plan of treatment is, *par excellence*, the mode to be adopted. From a rather extended experience with the disease in question, in the State of Florida, I am prepared to say that all cases are amenable to treatment by quinine, if such treatment be entered upon within thirty-six hours of the onset. As this peculiar disease is not widely known I will state briefly that it occurs only in those persons who have been for a long time subjected to slow malarial infection, without the proper administration of quinine. So nearly does the general appearance of the patient resemble that of one with yellow fever that superficial observers have named the disease 'highland yellow fever.' The distressing symptoms are hæmaturia, intense nausea, and black vomit, extreme thirst, frequently repeated chills of a congestive character, and, at, times, sinking turns amounting almost to syncope. The remaining symptoms are those common to all other cases of remittent fever. In fact, I believe the disease in question is simply an aggravated form of remittent fever. Owing to the severe gastric disturbance, it is impossible to exhibit quinine in sufficiently large doses per orem, hence it is my custom to administer hypodermatically ten grains of the bisulphate of quinine three times a day at least.

"The object being to thoroughly cinchonize the patient, the frequency of the dose will depend upon how readily that end is attained. My friend, Dr. George Troup Maxwell, of Florida, is in the habit of combining morphiæ sulph., one-eighth of a grain, with each injection of quiniæ bisulph. Saline diuretics seem to me to act well by relieving the kidneys by flushing.

"As soon as the patient becomes thoroughly cinchonized the temperature begins to fall, the urine becomes clear, all other symptoms ameliorate, and the patient goes steadily and rapidly onward to the stage of convalescence. I have never lost a case treated in this manner within thirty-six hours of its commencement. Dr. Maxwell has met with equally good results, and in a larger number of cases. The position taken by some, that 'pure blood' is passed from the kidneys, seems to me untenable. It is impossible for a reasonable physician to believe that quantities of blood so great as some claim could be lost daily and the patient still live. Is it not more reasonable to suppose that the evacuations are urine colored by the coloring-matter of the red corpuscles, which have been disintegrated by the high temperature, and the coloring-matter of which, by loss of plasticity in the blood, has been allowed to exosmose into the urine?"

A NEW METHOD FOR THE DETECTION OF HYALINE CASTS.

Dr. S. E. Armstrong, of Passaic, N. J., sends us a description of a method of manipulation devised by him to facilitate the detection of hyaline casts in the urine. He calls attention to the value of these casts from a diagnostic point of view, since the presence of albumen alone is no certain evidence of the existence of nephritis, and its absence does not necessarily imply a healthy state of the kidneys. He writes: "The hyaline cast may be said to form the stroma of all other varieties—the oily, epithelial, granular, etc. It is always found in some of the different stages of any of the forms of Bright's disease, particularly in the first stage, when a recognition of the trouble is most to be desired. The propriety of making a positive diagnosis on the strength of this one sign may justly be questioned, but there are usually other symptoms, objective or subjective, to aid us. Of course, the use of the microscope in the search for hyaline casts is an absolute necessity. Two methods are usually taught, viz., staining and tilting the mirror. The first I regard as impracticable, because it involves too much trouble; the second, because it is unreliable. I have never been able to make the desired success of either, though I must confess that I have not frequently tried the former. There is another method, which comes to me in the nature of a discovery. Others may have known of it for years; I have not been able to find a description of it in the books, although it may be there. Briefly, it consists in preparing the specimen in the usual way, between a plain slide and cover glass. Then placing the slide in position and adjusting the focus, the observer, with his eye at the instrument, presses the cover glass down with a thumb on either side of the objective, and then the slide being held firmly by the clips, pushes the cover-glass a little bit forward and back. By this means he has the advantage of *looking for an object in motion;* also, a cast, if present, is made to pass, rotating on its long axis, through different planes of the fluid, *hence through different possible foci.* By this means alone it is almost sure to be discovered. But there is still another advantage in this method, viz., as the cast revolves through the liquid it gathers on, perhaps amorphous urates, vibriones, or whatever minute object it comes in contact with, and is thus brought out into bold relief. Of course we must by previous examination exclude granular casts, otherwise *after* manipulation we may be puzzled to tell which variety we have discovered; we must also be sure we have not rolled out a white blood- or pus-corpuscle, so that it misleads us into the belief that we have found a short one of either one or the other variety. Prolonged manipulation is neither necessary nor advisable."

MOVEMENTS OF A TAPE-WORM OUTSIDE OF THE BODY.

Dr. W. E. Driscoll, of Cowan, Ind., referring to a case recently reported in The Record by Dr. Bidwell, sends the following: "A stout German girl, aged twenty-three, came to me in November, 1884, complaining of indigestion. She also complained of other symptoms, which pointed, as I thought, to tape-worm. I ordered her to fast twenty-four hours, beginning in the morning. The second morning I administered a dose of the tannate of pelletierin. This was at eight o'clock. Twenty minutes later I gave her a cathartic of jalap and calomel. I then left the house, and returned at 11 A.M., three hours after she took the remedy. She had passed the worm, had washed it clean, and placed it in the chamber. It had considerable motion, but not enough to crawl upon the floor had it been out. The patient stated that she had passed the worm at least half an hour before my return, and that it moved violently, and notwithstanding she washed it in cool water from the hydrant, it continued to move many minutes after it was voided. The girl resumed her duties the next day (that of chambermaid in a hotel). The medicine made her 'drunk,' she said, but not sick. The worm came away in one solid piece, head and all, and measured thirty-three feet."

The Disease of the Working Classes.—Aneurism of the aorta is the disease of the working classes, according to Dr. Richter (*Arch. f. Chirur.*, xxxii.). The two great causes are chronic alcoholism and severe muscular exertion. The greatest number of cases occur between the ages of fifty and sixty, next between forty and fifty, and last between sixty and seventy. The arch of the aorta has the most aneurisms, then the descending portion, then the abdominal, and last the ascending portion.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, September 4, 1886.

THE VARYING RESULTS OF CONTUSION OF AN ARTICULATION.

TRAUMATISM, as is well known, is a frequent exciting cause of disease, calling into activity pathological processes which might otherwise have lain dormant for years. This, as has been pointed out by Verneuil, in Dechambre's "Dictionnaire Encyclopédique," is especially true of contusions where the tissues are bruised and rendered more vulnerable to the attacks of disease. But the results of contusion are varied, and a knowledge of the constitutional predisposition of the individual is essential to an approximatively correct prognosis of such injuries. This fact is well illustrated by the report of a series of joint injuries occurring in the practice of M. Verneuil (*L'Union Médicale*, June 19, 1886).

The first case was that of a young man, twenty-one years of age, who had fallen from a horse, striking heavily over the region of the great trochanter. The patient's mother had died of phthisis, and the man himself presented evidences of commencing tubercular trouble in the apices of both lungs. In spite of rest and appropriate treatment, the signs of osteitis of the hip soon presented themselves. The patient died in about three months from pulmonary disease, aggravated by the confinement and exhaustion consequent upon the coxitis. At the autopsy, the hip-joint was found in an advanced stage of disorganization, the head of the femur was nearly destroyed, and the joint was filled with tubercular fungoid growths.

The second patient was a strong, athletic man, twenty-two years old, who had fallen from a wagon on his hip. He suffered intense pain, was unable to walk, and was supposed to have sustained a fracture. Examination, however, showed simply a contusion of the articulation and of the surrounding tissues. The result of the injury was an acute rheumatic inflammation of the joint, which was, however, of short duration and yielded readily to treatment. The man was of a florid complexion, ate and drank a good deal, and had complained at times of slight pains in the legs, which he had attributed to exposure.

In the third case the patient was a girl, sixteen years of age, of good constitution, who had fallen violently on the left hip. She was treated at her home in the country for many months without much benefit, and was finally sent to a hospital. On admission she was found to be in excellent general health, notwithstanding her long confinement. She could not walk without the aid of crutches, and then only with difficulty. The affected hip was flexed nearly to a right angle, and the thigh could not be brought down on a plane with the other without causing tilting of the pelvis and curvature of the dorso-lumbar spine. After a careful examination a diagnosis by exclusion was made of neuromimetic coxalgia. This diagnosis was strengthened by the existence of ovarian tenderness and of areas of anæsthesia on various parts of the body. Upon placing the patient under chloroform, the limb could be at once restored to its normal position. It was retained thus for several days, bromide of potassium and various antispasmodics were exhibited, and the patient was sent home cured in a few days. Finally, there was another case, very similar to the last, in which there was apparent anchylosis of the elbow following a contusion of this articulation. The patient, a boy fifteen years old, was anæsthetized, with the object of breaking up the adhesions; but, to the surprise of the operator, the joint yielded immediately, the anæsthesia was complete, and there was no return of the contracture subsequently.

These cases are very instructive, showing, as they do, how varied may be the results of contusions of the articulations, and how much the prognosis depends upon the individual constitution of the patient. It is important also to remember that apparent anchylosis, following joint-injury, may be purely hysterical in character and easily amenable to treatment by reposition under anæsthesia and retention for a time in the normal position. Many of the alleged wonderful cures effected by the so-called bone-setters, and, in recent times, by faith-healers, are cases of this sort, and were they recognized, as they should be, by the medical attendant, the profession would be saved much discredit and quacks would be enabled to make much less capital out of their cures of cases "given up as hopeless by the most eminent surgeons."

A NEW BRAIN-FISSURE—THE PAROCCIPITAL.

PROFESSOR BURT G. WILDER, of Ithaca, has subjected a certain fissure, or, Ithacally speaking, "gyre," in the occipital lobe of the human brain to neuronymic and monographic treatment. The article may be found in the ventral portion of the *Journal of Nervous and Mental Diseases* for June, 1886. The fissure in question has heretofore been considered to form the posterior (caudal) extremity of the great interparietal fissure, but the investigations of Professor Wilder lead to a different view, and the fissure in question comes out from these investigations with a nosological enrichment and an anatomical autonomy that are most gratifying.

Professor Wilder believes that he has shown that the transverse fissure of Ecker, with which the interparietal fissures generally connects, caudal, *i.e.*, posteriorly, is not an independent fissure, but is made up of the caudal ramus and stipes of an independent fissure, *the paroccipital*. This paroccipital fissure is spoken of generally as the posterior division of the interparietal; but Wilder claims, from a study of a number of brains injected with alcohol, and otherwise prepared brains, that it is independent, and should be described as such. This new fissure is yoke-shaped, the yoke having two rami laterad,

and two stipes mesad (we are using here pure Wilderese), while the main bar is called the "zygon." We have never seen a yoke exactly like that figured by the distinguished neurotomist of Cornell. It comes [illegible] near to resembling that article, however, as the Great Dipper does to outlining a bear, and we are not disposed to complain.

Writers of anatomical text-books and republishers of Eker's cuts will have to bear in mind these two things, made probable at least by Professor Wilder's painstaking, though word-encrusted, researches:

First, The transverse occipital fissure, always figured as a separate fissure, is not such, but only a branch of the paroccipital.

Second, the posterior or occipital end of the interparietal fissure is to be regarded, perhaps, as an independent fissure (the paroccipital), and not as part of the interparietal.

Professor Wilder's article is accompanied with an excellent translation from Ithacan to English.

FIFTY YEARS OF MEDICAL MISSIONARY WORK IN CHINA.

The Medical Missionary Society of Canton, China, celebrated the semi-centennial anniversary of its existence on December 31, 1885, and a report of the proceedings, together with a review of the Society's work, have been forwarded to us.

An American physician and clergyman, Rev. Peter Parker, M.D., has the credit of establishing the first medical missionary hospital in China, fifty years ago. Dr. Parker was a pioneer in medical missionary labor, and was the means of causing a great deal of activity in this kind of work. His first hospital at Canton was directed by himself for twenty years. It was then placed in charge of another American, Dr. John G. Kerr, who is still there at his post.

The work of the medical missionaries at Canton has been a most laborious and useful one, and some of the gentlemen who have been so faithful deserve, perhaps, a wider recognition than they have received. The first Medical Missionary Society ever organized was started in 1838, by Drs. T. R. Colledge, Peter Parker, and Bridgman. Several gentlemen connected with this Society have made names for themselves in the medical history of China. Besides starting dispensaries and hospitals at various places in and near Canton, the advantages of modern surgery were given the Chinese. Dr. Parker, in 1844, performed lithotomy upon a Chinaman, "the first instance in ancient or modern times." In 1847 ether was introduced by Dr. Parker, and in 1848 chloroform was used in the Canton hospitals. In 1875 the first ovariotomy in China was performed at Hong Kong, by Dr. Young. One of the Canton medical missionaries, Dr. Benjamin Hobson, became the first medical bookseller in China. We are told that his books were very popular with the Chinese, and were extensively sold throughout that country and in Japan. As pioneer works in inculcating the principles of rational medicine, they have been undoubtedly of immense service.

Dr. Kerr, who has been at Canton now for thirty years, has been a most industrious laborer in this field. We find credited to his pen original works or translations into Chinese to the number of more than a dozen, besides the editing of a Chinese medical periodical called the *Western Doctor*.

As Dr. Kerr's works include "Treatise on Medicine" (six volumes), a "Manual of Operative Surgery," treatises on Diseases of the Eye, Skin, Hygiene, Vaccination, Syphilis, and Symptomatology, besides a work in two volumes on "Materia Medica," it may readily be supposed that the author is a gentleman of scholarly attainments as well as large productive ability and persistent industry.

Since the foundation of the original Mission Hospital at Canton there have been a score of other similar institutions established in China, and the work is constantly progressing.

AN AMICABLE DISCUSSION ON HOMŒOPATHY.

We have already alluded to the polite controversy which has been taking place in Boston between regular physicians and the homœopaths of the University School of Medicine. Dr. Conrad Wesselhoeft having last year delivered a lecture on homœopathy before the Boylston Medical Society, Dr. V. Y. Bowditch this year delivered an address on homœopathy before the Hahnemann Society. Dr. Bowditch's address was directed to the answering of a number of set questions propounded by the homœopaths. In answering these questions the lecturer presents the position of rational medicine toward dogmatic medicine in a courteous, yet logical and forcible, manner. We cannot but believe that such efforts as those of Dr. Bowditch will help to infuse into the profession a more fraternal feeling. The splitting of the profession into "schools" lowers us continually in the eyes of the public. Dr. Bowditch reminds us that while individuals disagree, there is a common bond of unity which cannot be ignored by honest men. "We are *all*," he says, "members of a profession which, when regarded in its true light, above the plane of party strife and mere selfish gain, I regard as the finest and noblest of all, and the feeling grows stronger within me with each year of practice. There is that in it far above the mere desire and ability to cure disease—that which can soothe all regrets for possible failure and disappointment in our daily work—I mean the power of human sympathy; the power which bids the young mother silently and gratefully press the hand that helped her in her hours of trial; the power that impels the dying man, at the very last, to turn to him who, though powerless to save, yet, by a word, a look, a touch of the hand, gives strength and courage to one just passing to that 'undiscovered country from whose bourn no traveller returns.' In the midst of discord and disappointment let us keep this thought before us, gentlemen, and at the end perhaps we may be permitted to see our past life, as it were, stretched before us, and feel that we have done our small share toward making our chosen profession what it should be—a blessing to all mankind."

Such sentiments as these should ever be borne in mind by the physician. They will be a better help to a successful life than a whole bookful of worldly wise instructions as to how to dress up "the physician himself."

A TEMPERANCE HOSPITAL.

A RECENT number of the *Lancet* gives an interesting account of the exercises attending the anniversary of the Temperance Hospital in London. This is a general medical institution, where a cardinal principle is the avoidance of the use of alcohol in any form. During the thirteen years of its existence, it has not been found necessary to administer alcoholic stimulants on more than three occasions. In the ten and a half years of its existence up to the year 1884, it had treated fifty-three cases of typhoid fever without alcohol; out of this whole number, five deaths occurred; twenty of the patients were abstainers from the use of alcohol, while the remainder had been drinkers to a greater or less extent. Of the fatal cases, four were non-abstainers. Statistical tables were presented showing the relative results of treatment, with and without alcohol, in acute rheumatism, pneumonia, bronchitis, etc.

While all will admit that alcohol, like all other remedies, is abused, yet we fail to see that the facts narrated with regard to this institution are particularly striking or present any especial lesson. Most of us would be very loath, to say the least, to discard the judicious use of alcohol in either private or hospital practice. The above statistics may possibly show that we could get along with less than we use at present, but that is all. Fifty-three cases of typhoid are not many. The efficacy of any plan of treatment with this number cannot be well demonstrated. The disease is in many localities a mild one, it requires no stimulants; this is the case in some years here in New York; at other times, the disease is from the outset marked by severe prostration, and requires stimulation at once. We have never found anything more useful for this purpose than the judicious employment of alcohol. While we favor all measures designed to promote temperance, we question the utility of applying prohibitory principles to hospital practice.

THE NEW SKIN DISEASE.—Dr. E. J. Bergen, of Hope, N. J., writes: "Referring to your editorial in THE MEDICAL RECORD of August 21st, entitled 'A New Skin Disease,' allow me to say that the disease mentioned is by no means confined to the Western States, although while practising in Kansas I first became familiar with it, receiving in that State the popular name of 'Missouri Mange.' The author whom you quote has given a very correct description of the trouble, and there is no doubt to my mind that, as Dr. Engstad states, the disease is due to a vegetable parasite, as I have repeatedly, during the vesicular stage, found the elongated cells mentioned. The past two years I have seen and treated a number of persons afflicted with the disease, and with uniform good results, employing the following method: First, a thorough washing with soap and water; while the skin is still soft, apply lightly a solution made in the following manner: To two ounces of slacked lime add one pound of sulphur and four quarts of water, adding from time to time water so that after boiling one hour there may be four quarts of the fluid, strain through muslin, and it is ready for use; one application is usually sufficient. The above treatment was suggested by knowing the advantage of washing with an alkaline solution before using sulphur ointment in ordinary scabies.

News of the Week.

NURSES FOR SMALL CHILDREN.—About a year ago a training-school for nurses was opened at the Post-graduate College Hospital. The profession will be interested to know that in connection with the usual advantages offered to pupil nurses, viz., training in the care of adult patients, this school has been able to give a special practice in the nursing of babies and young children in the ordinary infantile diseases—an extremely important division of their work.

MERRITT H. CASH PRIZE ESSAY.—The Medical Society of the State of New York offers to physicians of this State (New York) a prize of one hundred dollars, from the proceeds of the Merritt H. Cash Prize Fund, for the best essay on any medical subject that shall be approved by its Committee on Prize Essays. Essays for this prize must be printed by type-writer or otherwise, and sent to the Committee without any indication of authorship. The names of authors should be endorsed in sealed envelopes accompanying the essays, and bearing upon the outside mottoes or other devices which are duplicated on the essays. Essays for competition must be sent to the Chairman of the Committee, Dr. George F. Shrady, 247 Lexington Avenue, New York City, on or before December 20, 1886, in order that the Committee may have time to examine them and report at the next annual meeting of the Society, February 1, 1887.

"ROUGH ON RATS," AN ARSENICAL POISON.—Cases of poisoning by this preparation are of such common occurrence that it is well to remember that it is made simply of arsenious acid. The antidote is the hydrated oxide of iron, which can be prepared extemporaneously by adding an excess of aqua ammoniæ to the tincture of the chloride of iron. The mixture should be strained, and the magma then washed with water to remove the ammonia. Dialized iron, to which magnesia has been added, will also serve as an antidote. The sale of this preparation ought to be placed under the same restrictions as that of any other active poison.

SPAYERS RUN MAD.—Under this title *Leonard's Illustrated Medical Journal* quotes from an editorial in THE MEDICAL RECORD of last April, which it says was written "in defence of the recent craze for the spaying of women," and adds the comment: "If the arguments of the abortionist, the roué, and the prostitute are to become the arguments of the laparotomist, it is about time gynecology became one of the lost arts." This is very discouraging. Esteemed contemporary, we were on the other side. Read the article again, and try the effect of a second stroke.

THE DEATH OF DR. HERMANN MAAS is announced. Dr. Maas was professor of surgery in Würzburg, and was but forty-four years of age at the time of his death.

MEDICAL STUDY IN JAPAN.—The number of students in the Imperial University at Tokio is said to be nearly one thousand, a large portion of which are students of medicine. Five of the professors in the medical faculty are Germans.

Hydrophobia in Camels.—Several cases of hydrophobia occurred some time ago among a herd of camels in Algeria. The animals exhibited unmistakable symptoms of the disease, but there were no evidences of their having been bitten. A mad horse had gained admittance to the place where the camels were pastured, and it is supposed that the disease was transmitted through saliva which had fallen from the horse's mouth upon the grass, and the camels had received the poison through abrasions in the mouth from which these animals frequently suffer.

A New Russian University.—The Russian journals report that a private university, reserved exclusively for women, will soon be opened in Moscow. The university will embrace three faculties: philology, mathematics, and natural sciences. Under the latter will be included a course for medical study.

Professor Semmola, of Naples, has been made senator of the kingdom of Italy. This is an honor which is seldom conferred upon any but politicians and in reward for political services, and is therefore so much the more noteworthy when given in recognition of purely scientific labors.

The Value of Antisepsis.—A member of the medical profession has published a fee list, in which he estimates the value of his services at the rate of $500 for a non-septic dressing, while a dressing in septic cases is made at the comparatively cheap price of $25.

Sozolic Acid.—This substance, called also orthoxyphenylsulphurous acid, is said to possess superior antiseptic properties. It has been used internally as well as externally in erysipelas, small-pox, pneumonia, phthisis, and other affections, with, it is claimed, excellent results.

A New Journal.—The first number of the *Jornal de Medicina e de Pharmacia* appeared on July 3d. It is published in Paris in the Portuguese language, and is intended for circulation in Brazil. The editor is Dr. Simeon da Fonseca.

Medical Practice in Belgium.—A complaint has been made in the Belgium Senate that foreign physicians are allowed to practise in that country without obtaining a diploma from a Belgium university, thereby doing an injury to the native practitioners. The Senate was requested to pass a law to prevent physicians with foreign diplomas from practising in Belgium.

Cremation in New South Wales.—In the Legislative Council of New South Wales, on June 3d, Dr. Creed introduced a bill entitled, "To authorize the establishment of sites and apparatus for purposes of cremation." The object of the bill is to legalize cremation under certain necessary restrictions.

Honors to an Irish Surgeon.—The Earl of Aberdeen, Lord Lieutenant of Ireland, recently conferred the honor of knighthood on Mr. Stokes, President of the Royal College of Surgeons in Ireland.

Cholera in Japan.—Recent reports state that cholera is prevalent to an alarming extent in Yokohama and Tokio, and also in Corea, in which country the mortality from the disease is very great.

An Untimely Death.—A female physician, Mlle. Ribard, who went with the expedition that accompanied Paul Bert to Tonkin, has died of dysentery in the hospital at Quang Yen. She made a specialty of diseases of the eyes, and had been very successful, having cured many of the mandarins, and was just about to perform an operation on the king's mother when she was prostrated by the disease which terminated her life.

Ethoxycaffeine, a derivative of caffeine, discovered by Filehne, has been used by Dujardin Beaumetz in the treatment of migraine, with, it is said, very good results.

Night Medical Service in Vienna.—Baron Mundy has recently induced the municipal authorities in Vienna to establish a night medical service similar to that in existence in Paris and New York.

A Night Pharmaceutical Service.—The municipal council of Paris has decided to establish a night pharmaceutical service. In order to procure the medicines prescribed by the physicians of the night medical service, the patients must apply to the nearest police station, whence they are directed to the nearest apothecary whose name is inscribed upon the list. The medicines will be paid for by the city if the patient's circumstances are such as to require it; but if able, the patients must pay for the prescription, and thirty cents in addition as a compensation for the druggist's night work.

Hydrophobia is said not to exist in Lapland; but two dogs brought from that country, having been inoculated by M. Pasteur, contracted rabies, thus proving that Lapland dogs are not refractory to the disease.

Small-Pox in Zurich.—In May, 1883, owing to the clamor of the anti-vaccinationists, the authorities at Zurich abolished compulsory vaccination. For the twenty-seven months prior to this time there had been but 7 deaths per 1,000 from small-pox. In 1884 there were 11 deaths per 1,000; in 1885 there were 72, and in the first three months of 1886 for every 1,000 deaths from general causes there were 85 from small-pox.

Medicine in Tennessee.—It is said that incompetent physicians and quacks of all kinds are flocking in great numbers to Tennessee, and in some places actually supplanting the regularly educated medical men.

Poor Chicago.—The St. Louis *Weekly Medical Review* says that Chicago maintains six medical societies, seven medical colleges, and eight medical journals.

Inebriety cannot be prevented by throwing the responsibility on the inebriate, and punishing him for this, as if for crime. He is a sick man, and must be taken out of his surroundings and fully quarantined until he can recover.—*Quarterly Journal of Inebriety.*

A New Caustic.—It is reported that a mixture of calomel and benzol makes a very efficient caustic for the removal of epitheliomatous growths.

Medical Rapacity.—The London *Standard* tells of a surgeon who demanded a hundred guineas for a slight operation performed in his office, the entire visit lasting only fifteen minutes. After coming down successively to fifty and twenty-five, the surgeon finally accepted ten guineas on account.

Iodoform for Army Use.—Professor Mosetig-Moorhof considers that iodoform is the best antiseptic in time of war. It does not irritate the wound, and its action is invariable and permanent. At Belgrade, where this antiseptic was used, there were only 19 deaths among 824 wounded. Iodoform is less caustic than other antiseptic substance.

Treatment of Burns.—It is said that essence of peppermint painted over a burn will quickly relieve the pain.

Yellow Fever at New Orleans.—A Norwegian vessel from Aspinwall recently arrived at Ship Island quarantine, New Orleans, with six of her crew of twelve men down with yellow fever. No danger of the spread of the disease exists, as the vessel was quarantined and all necessary precautions taken.

The Pasteur Institute has received a donation of 100,000 francs from the Russian Government.

Dissection in Washington.—President Cleveland has vetoed the bill legalizing dissection in the District of Columbia, on the ground that the bill failed to provide sufficient safeguards against the delivery of bodies to unauthorized persons.

Massage in Glycosuria.—Finkler recommends massage in the treatment of diabetes. He has employed the method a number of times, and asserts that the quantity of sugar is considerably lessened, even when the patients continue with a mixed diet. Profuse perspiration begins shortly after the commencement of treatment, and the patients so treated almost always increase in weight.

Oxalic Acid as an Emmenagogue.—Dr. Poulet recommends oxalic acid very highly in the different forms of amenorrhœa, and says that no other emmenagogue can compare with it in the certainty of its effects. He uses the following preparation: Oxalic acid, 30 grains; syrup of orange-peel, 2 ounces; water, 6 ounces. The dose is a tablespoonful every hour.

Valerian in Diabetes.—According to M. Demange valerian is an excellent remedy for use in diabetes insipidus. It is given in doses of from two to four drachms a day.

Congenital Anidrosis.—At a recent meeting of the Obstetrical Society of Boston, Dr. C. E. Stedman reported a case of eclampsia, in which he had given three doses of one-third of a grain each of pilocarpine, without inducing perspiration. The hot-air bath was also ineffectual. He afterward learned that the patient never perspired, even when in health.

A National Orthopedic Association.—The *Medical Review* enters a protest against the movement which is said to be on foot, to form a subsection of orthopædics to the section of Diseases of Children of the American Medical Association. It says that orthopædic surgery is of sufficient importance to deserve a section to itself, and proposes the formation of such a section, or else the establishment of a national society of orthopædists. The latter would seem, under the circumstances, to be the more feasible plan.

Not a Good Opening for Physicians.—There would seem to be danger of a plethora of physicians in Kansas City, for the *Medical Index* of that city says that nearly fifty physicians have settled there during the past two months.

The Second Congress of Russian Physicians will be held in December of this year, in Moscow. The president of the association is Professor Sklifassovski.

A Cure of Stricture by Suggestion.—M. Ramey, of the Military Hospital of Saint Martin, recently reported a cure of spasmodic stricture of the urethra by hypnotic suggestion. Internal urethrotomy had previously been performed without relief. The patient was hysterical, and could be readily hypnotized.

A Handsome Bequest.—Dr. Orjekhovski, who died recently in Warsaw, left over 200,000 roubles to a charitable society of that city.

Dr. Ferreira dos Santos, who was commissioned by the Brazilian Government to study Pasteur's methods, with a view to the establishment of an institute for the prevention of rabies in Rio de Janeiro, has arrived in Paris. He brought with him a letter to Pasteur from Dom Pedro II., and also the grand cross of the order of the Rose.

M. Brown-Séquard has been elected titular member of the Académie des Sciences, having received twenty-eight votes more than his competitor, M. Germain Sée.

Gastric Catarrh in Moscow.—An unusually large number of cases of acute catarrhal gastritis have occurred in Moscow in the last few months. No cause has been found for the prevalence of the disease. Bacteriological examinations of the excretions have given negative results.

Condemnation of a Midwife.—In Altenburg, recently, a midwife was sentenced to imprisonment for two years, because she advised the parents of an infant suffering from ophthalmia not to seek medical advice. The only treatment consisted in local applications of chamomile tea, and the child lost one eye in consequence.

Auscultatory Percussion.—In an excellent historical article on auscultatory percussion in *Lo Sperimentale* for July, 1886, by Dr. A. Bianchi, the author gives full credit to Drs. Cammann and Clark for priority in the use of this diagnostic method. Auscultatory percussion has been rather extensively practised of late in Italy, but the first writers on the subject did not seem disposed to acknowledge the claim to priority of the American physicians.

A Chair of Evolution.—Herr Paul v. Ritter, of Basle, has signified his intention of leaving 300,000 marks to the University of Jena, for the purpose of promoting the study of philogenetic zoology according to the Darwinian theory. He will give 130,000 marks at once, and the balance will be paid after his death. Professor Haeckel, of Jena, an enthusiastic teacher of evolution, proposes to use the gift for the establishment of a professorship of zoology to be called, after the donor, the Paul v. Ritter Chair of Zoology.

Reports of Societies.

British Medical Association.

FIFTY-FOURTH ANNUAL MEETING,

Held at Brighton, England, on Tuesday, Wednesday, Thursday, and Friday, August 10, 11, 12, *and* 13, 1886.

MEETINGS OF SECTIONS.

SECTION IN SURGERY.

THURSDAY, AUGUST 12TH—THIRD DAY.

THE President of the Section, MR. ERICHSEN, took the chair shortly after 2 P.M.

DR. GEORGE HARLEY, F.R.S., then read two papers on

HEPATIC PHLEBOTOMY AND PUNCTURE IN HYPERTROPHIC CONGESTIONS OF THE LIVER.

Only one paper on the above subject had been announced, but Dr. Harley divided his paper into two, and thus secured fifteen minutes for each, a proceeding which called forth an indignant protest from one gentleman present.

In his first paper he described two

CASES OF HEPATIC PHLEBOTOMY,

in which he had withdrawn about a pint of blood from the liver by a trocar. These cases were published a month or two ago, and have already been referred to in THE MEDICAL RECORD.

In his second paper he compared

THE PUNCTURE OF GLISSON'S CAPSULE

to that of the tunica vaginalis in orchitis (which, however, I may remark, is not much practised), to acupuncture in sciatica, and to incising a whitlow. He described cases in which he had performed the operation, and said he used trocars varying in size from Nos. 2 to 5 of the liver trocar. Each one was from one to two inches in length. In one case, although the liver was as hard as a fibroid tumor, diminution in size followed the operation and the patient thought his liver became much softer. One of his cases was that of a gentleman who had lived many years in the tropics (South America). Being very wealthy, he had lived very freely, partaking of champagne unsparingly. As a consequence of this he began to suffer from hepatic symptoms, and when he came under treatment was suffering severely. He was anxious to obtain immediate relief, as he desired to leave England shortly.

THE OPERATION OF PUNCTURE OF THE LIVER

was proposed to him, to which he readily assented, and his liver was accordingly punctured in several places. He received great benefit from the operation, and returned to South America in a much better state of health. The improvement continued for some months. He then began to indulge in excesses again, thinking he could do so with impunity. This caused a relapse, and he had again to place himself under treatment.

MR. KNOWSLEY THORNTON then read a paper on

THE SURGERY OF THE LIVER.

and related some cases in which that viscus had been surgically dealt with. In one of his cases, what had been supposed to be ovarian disease proved to be a large, single hydatid cyst of the liver, of such a size that the gall-bladder was displaced into the right iliac fossa, had become adherent to the uterus, and (before the operation) was taken for the right ovary. The cyst was cleared out, the sac then sponged out with pure tincture of iodine and sewed up with the same sutures as those uniting the abdominal wound. The patient did well. Another case was that in which puerperal peritonitis had caused adhesion of the gall-bladder. Having related a case in which he had successfully removed a number of gall-stones from the gall-bladder, Mr. Thornton described one in which he had opened an abscess of the liver through the pleura, having previously sutured the two layers of the pleura together, so as to form a channel through which the pus might pass without entering the cavity of the pleura. He approved of antiseptics and, among them, he preferred a weak solution of corrosive sublimate. He believed in using large quantities of (weak) antiseptic solutions, so as to wash away every diseased particle. Where you could not destroy the virus, attenuate it. The liver should be treated surgically in the same manner as other organs.

MR. WILLETT then read a paper on

CHOLECYSTOTOMY,

of which he was the author jointly with Mr. W. A. Meredith. Mr. Willett described a case occurring at St. Bartholomew's Hospital, London, in which Dr. Gee thought obstruction of the common hepatic duct had occurred. The abdomen was opened, and the gall-bladder was found to be distended with sixteen ounces of clear serum, which were drawn off. There was complete obliteration of the common duct. For about a week an almost continuous flow of fluid took place from the opening made into the gall-bladder. Should

CUTTING INTO AND DRAINING THE GALL-BLADDER

be performed until aspiration had been tried, especially when there was a possibility of finding the duct obliterated? Mr. Willett suggested

THE DESIRABILITY OF MAKING AN ENTERO-CYSTIC FISTULA,

so as to render the operation complete. It had occurred to him in this case that he might do this, but he refrained. In future cases of the kind he would certainly do so. There were two sites at which this fistula might be formed. One was at the junction of the first and second parts of the duodenum; the other was where the ascending joined the transverse colon. From a physiological point of view the duodenal site was preferable, but the operation was more difficult of performance there, the space in which to work being smaller and deeper. The physiological reasons were also less valid than might be supposed, because examination of the secretion from the liver in these cases showed the biliary constituents to be greatly diminished in amount, the secretion being, in fact, little but serum. It was much easier to make a fistula into the colon. The colon and the gall-bladder lay side by side, and almost in the line of the incision. The artificial opening into the gall-bladder should be made at its lowest point, as there was then a probability of the gall-bladder ultimately contracting and forming merely a duct.

MR. HOWARD MARSH then read a paper on

A CASE OF ABSCESS OF THE LIVER, OPENED BY A SINGLE INCISION.

The abscess proved to contain thirty-six ounces of pus. He thought the operation might be safely performed on children. Abdominal surgery in children, he remarked, was as safe as in adults. Ovariotomy, removal of the kidney, gastrostomy, and operations for the relief of intussusception, had all been successfully performed on children. In operating on children it was desirable to avoid loss of blood as much as possible, and also that the operation should be completed with as little delay as possible.

Mr. Lawson Tait (Birmingham) then read a paper on

THE SURGICAL TREATMENT OF DISEASES OF THE LIVER.

Mr. Tait had operated on the liver in fifty cases in all. He exhibited a table of his cases, and made a few remarks on some of them. There were seven cases of

EXPLORATORY INCISION INTO THE LIVER,

of which one terminated fatally. Dr. Clifford Allbutt and himself had thought they felt a distended gall-bladder, but at the time of the operation they found what they had taken for the distended gall-bladder to be a colloid mass in the liver. He had performed hepatotomy in thirteen cases, all of which recovered. Of this number, nine were cases of hydatids, two were cases of cysts, one was a case of gall-stones, and one was one of tumor of the liver. The remaining cases (thirty) were all cases of

CHOLECYSTOTOMY.

One of those was a case of cholæmia, two were cases of distended gall-bladder, one a case of suppurating gall-bladder, two were cases of gall-stones crushed, and the remaining twenty-four were cases of gall-stones. Out of the thirty cases, one (a case of gall-stones) ended fatally, and two died since the operation from the progress of cancer of the liver. One of these was a case in which the operation was undertaken for distended gall-bladder, and the other was one in which it was done to remove gall-stones.

Mr. Tait said the secondary results were successful in all but one of the forty-six patients who recovered, and in that one jaundice had been present. Where jaundice was present, his experience was that the secondary results were often not satisfactory, and he therefore looked on cases in which jaundice was present with grave suspicion. He referred to a case in which he had operated on the kidney and removed a mass of gall-stones which had found their way down. The disease was really hepatic in origin, although it was cured by operating on the kidney. His thirteen cases of hepatotomy had been performed mostly for dilatation of the liver. In one case of gall-stones for which he performed hepatotomy, he

REMOVED A PIECE OF THE LIVER SUBSTANCE

in order to afford space for the removal of the gall-stones.

Mr. Erichsen having said a few words, the discussion was opened by Dr. Royle (Manchester), who described a case in which sixty gall-stones were found in the gall-bladder, and the patient had never passed a gall-stone and never had a symptom of any.

Dr. David Boys Smith (Netley) said puncture of the liver had been claimed by Dr. Harley as a novel operation, but it was the most ancient operation in the world. It had been performed by the Chinese for ages, and was systematically done in China now. He had had twenty-five years' practice of it. He described a case in which, while searching for pus, the liver was punctured in all directions. He did not find any pus, but the patient was benefited. As one of the professors at the Army Medical School, Netley, he protested against Dr. Harley's insinuation about the erroneous teaching of the schools as to the treatment of hepatic affections. He wished Professor Maclean had been able to be present, as he would have said how many times he had done it. He would, however, read one sentence from a letter from Dr. Maclean to Dr. Harley. Dr. Maclean wrote that he had "often done it and withdrawn five or six ounces of blood with benefit." Dr. Smith concluded by referring to a case in which the liver had been punctured and a fatal result (from hemorrhage) had ensued.

Dr. Cullimore claimed for Dr. Harley the credit of the operation, and defended the

PRACTICE OF TAKING BLOOD FROM THE LIVER.

He said he had himself suffered twice from abscess of the liver, and leeches placed over the liver gave him great relief.

Mr. Willett, Surgeon-Major Black, Mr. Prankerd, Dr. Ewart, and Dr. Johnson (late of Shanghai) also spoke and discussed the treatment of hepatic disease, both medically and surgically. Some of the speakers thought surgical measures should not be adopted until mercurials, salines, and other remedies had had a fair trial.

Dr. George Harley then replied. He repudiated the statement that his idea was not original.

ACUPUNCTURE OF THE LIVER

had frequently been done. So had exploring for an abscess. But this was not hepatic phlebotomy. Dr. Boys Smith had referred to Dr. Maclean. He thought the latter ought to ask to be saved from his friends. He had in his hand the letter from Dr. Maclean to himself to which Dr. Smith had referred, and from which Dr. Smith had quoted one sentence. What Dr. Maclean did say was that he had "with a needle drawn a few ounces of blood from the liver." This was a very different thing from the performance of hepatic phlebotomy as advocated by himself. As to his statement as to the teaching of the schools, he could only say that he had studied five years in the schools of England and Scotland, and six years on the Continent, and had never yet been taught to operate on the liver. It was always laid down that operations on the liver were not to be attempted. He had been taunted with having only two cases of hepatic phlebotomy, and with not trying other remedies. The fact was, patients were not to be met with every day who would submit to the operation.

As to the second objection, in his cases *everything* had been tried—mercurials, salines, and every conceivable remedy—and without effect. In one of his cases it was only when the patient was much reduced, suffering from dropsy and unable to stand, that permission to operate was given. He operated on her in that condition simply because he could not get leave to do so before.

Dr. Simon Fitch (Nova Scotia) then read a paper on

THE DOME-TROCAR AND A CURIOUS QUESTION OF PRIORITY,

and Associated Instruments in Paracentesis, Aspiration, Transfusion, Ovariotomy, and Tunnelling the Enlarged Prostate.

Dr. Fitch showed his trocar and explained the method of using it. At the conclusion of his demonstration a rather lively passage-at-arms took place between him and Dr. Ward Cousins, a Vice-President of the Section. The latter said it was the same as his own trocar (barring two trifling modifications, which he mentioned), and he was much obliged to Dr. Fitch for taking up his idea. Dr. Fitch rejoined that he should be very glad to see any book or pamphlet in which Dr. Cousins had described his trocar, and asked how long it was since Dr. Cousins brought his trocar out? Dr. Cousins having admitted that it was only a few years, Dr. Fitch rejoined that his was fifteen years old, and, on Dr. Cousins retorting that he should have brought it out before, said he had. It was described in the "Proceedings of the International Medical Congress at Philadelphia" (1876), and figured in a London surgical instrument-maker's catalogue for 1871. The whole scene was most amusing. No one, however, could imagine for one moment that Dr. Cousins had really appropriated Dr. Fitch's idea; his indignation was too genuine. Dr. Cousins is the inventor of so many useful appliances that he can well afford to lose the credit of one.

Mr. Edmund Owen then read a paper on

PSOAS ABSCESS; WHEN AND HOW TO OPEN IT.

Mr. Owen said there was no disease the treatment of which had derived a greater impetus from the introduction of antiseptics than psoas abscess. By antiseptics he did not mean the use of the spray. The spray was a cooling down in more senses than one, and the surgeon did not now have to look through a cloud of carbolic vapor at his patient. By the use of antiseptics he meant antiseptics as used by the great masters in surgery, whether by Tait, Gamgee, Savory, or Lister. Twenty years ago every surgeon preferred to leave a psoas abscess alone so long as it remained unopened. Stanley, writing forty years ago, said a psoas abscess might disappear. Could it? Mr. Owen said that in an extensive out-patient experience, extending over years, he had only seen one case in which, after a fusiform tumor had been detected ascending along the iliac fossa, he had seen it disappear. Aspiration was useless, for it refilled. When evacuation of the abscess was performed, it should be done thoroughly, and no useless temporizing measures made use of. During delay the pus would be burrowing out for itself an extensive ramifying cavity. A free anterior and posterior opening should be made, and the wound thoroughly drained. The sac should be washed out with a warm antiseptic lotion, and a drainage-tube the size of a cedar-pencil passed through. The wound should be covered with sublimate gauze, then some oakum placed over it, and the dressings changed as seldom as possible. He had employed as the antiseptic lotion a warm solution of corrosive sublimate (1 in 1,000). He should, however, in future discard the use of the sublimate, as he had had a case which died in four hours with black urine, due, he believed, to the absorption of the sublimate. Mr. Owen, in concluding, summed up his conclusions as follows: 1. Spontaneous absorption of psoas abscess is impracticable. Sooner or later it must be evacuated, either by nature or art, and the advantage is on the side of art. 2. The sac should be opened both in front and at the back, and irrigated. For a small abscess a single opening at the back might suffice. 3. Antiseptics should be employed. 4. The operator should bear in mind that pus might collect on the opposite side after evacuation of the abscess. If any rise of temperature take place, a second abscess should be suspected, and, if found, evacuated at once. Bilateral abscesses should be attacked simultaneously, as their cavities frequently communicate. In reply to a query from a member as to the source of his method, Mr. Owen replied that it was neither English, French, Scotch, nor Italian, but Welsh, thereby signifying that the idea was his own, and that he had not borrowed it from anyone.

Mr. William Adams then read a paper on

THE TREATMENT OF CONGENITAL DISPLACEMENT, THE SO-CALLED CONGENITAL DISLOCATION OF THE HIP-JOINT, BY LONG-CONTINUED RECUMBENCY AND EXTENSION.

A model of Mr. Adams' new extension couch was exhibited in a room adjoining that in which the meetings of the Section in Surgery took place.

SECTION IN OTOLOGY.

Wednesday, August 11th—Second Day.

ADVANCES IN OTOLOGY.

Mr. G. F. Hodgson, of Brighton, delivered his Presidential address, in which he traced the history of the progress of this department of surgery during the last half-century, and concluded by expressing a hope that the Section would not suffer by being presided over by a general practitioner.

Dr. Grant then read a paper on

PULSATING TINNITUS.

and another on "The Use of the Tuning-fork." In some remarks on this Dr. Erskine explained Hartmann's method of recording deviations of hearing-power. And Dr. Ellis proposed to relate a case and exhibit the patient at the dispensary the next morning, when cases were to be exhibited by others.

Mr. Cresswell Baber was then called upon for his paper on

THE EXAMINATION OF THE NASAL CAVITIES FROM THE FRONT.

which he read, pointing out as he went to the appearances to which he most wished to draw attention on enlarged diagrams, which he had had copied on a suitable scale from the illustrations to his recent work on the nose. He drew particular attention to the tubercle of the septum, and the manner in which this part causes variations in the image. This paper was well received, and Mr. Spencer Watson congratulated the author on the accuracy of his diagrams and the care which he had taken in recording graphically so many different images.

Mr. Lennox Browne said he had found great difficulty in representing the anterior image, and he did not think that any considerable success had been reached in such conventional diagrams of this part. At any rate, they were far less useful than those which were made of the larynx, and he fancied they would not be of much service to the general practitioner.

Dr. Grant thought that the section of the nasal cavities exhibited by Mr. Baber would afford a more satisfactory basis for recording cases than the view obtained in anterior rhinoscopy.

Mr. Baber replied that his diagrams were not intended so much for the general practitioner as for those who devoted much attention to diseases of the nose, and he had therefore brought them before the Section of Otology; and he handed round a sheet of clinical outlines intended for recording such cases on which, besides the anterior view, there was also a diagram of the posterior image as well as the sections which Dr. Grant preferred; and as they were easily detached, any or all could be used as found convenient. As Mr. Baber had mentioned that he had recorded on his diagrams between three hundred and four hundred cases, and as neither of his critics professed to have used them once, the impression conveyed was that the objections were futile.

Dr. Greville Macdonald then read a paper on "The Functions of the Nose." It was of quite an elementary character, and indeed could scarcely be otherwise, as the writer has only lately begun to study the subject.

Dr. Ellis then related a case of "pulsating tinnitus," and proposed to exhibit the patient the next day.

The Section then adjourned.

SECTION IN THERAPEUTICS.

Wednesday, August 11th—Second Day.

Dr. Lauder Brunton delivered the address. He recognized four stages in the development of medicaments: In the first crude drugs were employed, prepared in the roughest manner; in the second these were converted into more active forms, as extracts or solutions; in the third active principles were employed, as morphine and quinine; in the fourth we try to make substances possessing the action we desire. We are now just entering on what may be called the "iron age of pharmacology," which began, about twenty years ago, with the researches of Fraser and Crumbrown upon the connection between chemical constitution and physiological action. He then entered upon a curious and somewhat strange analogy between the flesh-hooks of Shiloh and the qualities of drugs—which illustration he labored at for a considerable part of the address. He concluded with a reference to

the small amount of pain inflicted upon animals, never wantonly and never carelessly, comparing that with the suffering endured by patients, and thus justifying experiments which have been denounced by fanatics, while in reality they advance the means of relieving pain and prolonging life, not only in man but in animals themselves.

Professor Oscar Liebreich then read a paper on

LANOLIN,

the new fatty substance with which his name is associated, in which he dwelt upon its physical properties and therapeutical uses. He did not profess that it was an absolute novelty, for it had been employed at a very early period, but only in a very repulsive form. In reviving its use he has obtained it in a state which leaves nothing to be desired, and the large quantity of water with which it will unite and the great readiness with which it will pass through the integument, carrying with it the medicaments with which it is charged, place it at the head of all substances for the basis of all ointments. Specimens of lanolin—pure and impure—were handed round, and the President thanked the learned professor for his paper.

Dr. Shoemaker, of Philadelphia, read a paper on

HAMAMELIS VIRGINICA,

in which he expressed considerable confidence in the value of this drug.

Dr. Edward Mackey, of Brighton (Vice-President of the Section), then read an interesting paper on

THE USE OF RESORCIN IN GASTRIC AND CUTANEOUS DISORDERS.

He drew attention first to its antiseptic properties, pointing out that a two per cent. solution retards putrefaction, but does not irritate the tissues. Sometimes a five per cent., or even a ten per cent., solution may be employed, but then considerable irritation may be excited, while the weaker lotions are generally effectual. Internally he had usually employed five-grain doses. It is not nasty, but the taste is easily tolerated by almost all patients. He usually gave it in water, with a little glycerine, or in chloroform water; doses of twenty or thirty grains have been given, but they give rise to febrile disturbance, while from thirty to sixty grains cause giddiness, prostration, anxiety, collapse, and unconsciousness. He therefore did not approve such doses. It was quite true that full doses lower the temperature, but the effect is only temporary and of doubtful advantage, so that resorcin may be said now to have passed out of the list of antipyretics. Two cases of gastric ulcer, treated in the County Hospital, with five-grain doses three times a day, began to improve as soon as the resorcin was taken, and completely recovered under the treatment. In one of these anæmia was so extreme that he had resorted to hypodermatic injection of dialysed iron, as employed by Dacosta. Twelve cases of gastric catarrh among the out-patients of the hospital, varying in age from twenty-seven to fifty, all of whom had been vainly treated by bismuth, magnesia, soda, prussic acid, and the usual prescriptions, soon got better under five-grain doses of resorcin *ter-die*. The drugs seem to stimulate and disinfect the mucous membrane. In children's diseases he had not found it so successful; he had given it in doses of two and three grains to children, but found that it neither relieved diarrhœa nor disinfected the evacuations. In skin diseases it was a valuable parasiticide; a ten per cent. solution sometimes relieved psoriasis. On ulcerating mucous surfaces it improved the condition and disinfected the discharge, as for example in otorrhœa.

Mr. Wilberforce Smith said that it seemed to act like carbolic acid, and he would like to ask whether the author had separated the effect from that of physiological treatment, which was often so effectual. Dr. Mackey replied that he had already pointed out in the paper the differences between resorcin and carbolic acid, the most important being that it was decidedly less irritant. As to physiological treatment, of course, his two in-patients had the benefit of rest, proper diet, and hospital care; but among the out-patients there was little opportunity for securing such benefit, and all we could do in such cases was to give physic, as the patients could not, as a rule, comply with other directions.

A DISCUSSION ON ANTIPYRETICS

was then introduced by Dr. Carter, of Liverpool, who had a number of charts recording cases illustrative of his remarks. He placed quinine at the head of all antipyretics, especially where any malarial influence was suspected, and he saw many malarial fevers in the Liverpool Infirmary. He usually gave a few doses of ten grains, and did not approve the enormous quantities often advised, and would fear to give them where a tendency to coma was observed. In some of these rare cases, when the temperature suddenly ran up to 106° F., he preferred cool baths, and perhaps a blister to the nape of the neck. In one instance he saw sinapisms applied to the calves without rousing the patient, although they had been so assiduously used that ulceration ensued and lasted a long time. Salicylate of soda he found very certain in its effects and the best remedy in rheumatic cases, but it had the disadvantage of sometimes causing great depression, and therefore for non-rheumatic patients he did not use it. Antipyrine he had found very effectual, but the effect was evanescent, and therefore the doses had to be given at frequent intervals; he did not give large quantities, but contented himself with ten grains every hour at first, and when the temperature had been reduced, at longer intervals. He mentioned some interesting cases, showing the certainty with which this drug will lower the temperature; one or two of which had converted a house surgeon, who was very sceptical of this, into a full believer. Curiously, he found antipyrine, though generally so certain, of no use whatever in severe febrile anæmia, and this corresponds with the observation that has been made that it produces no effect on the blood; the form, color, and other properties of the globules being unaltered by the drug. In other cases he considered antipyrine the best agent, and likely to become the general favorite.

Dr. Leech thanked Dr. Carter for the careful manner in which he had introduced this discussion, and suggested that each antipyretic may have its own sphere of action. In anæmia all of them frequently failed; on the whole, quinine is the best; he had given the large doses recommended by Liebermeister, and endeavored to time the doses in the manner advised by him. He thought that we should carefully study the duration of the action of our remedies, and that this was especially desirable in using antipyretics.

The time having now expired, the further discussion of this subject was adjourned.

Dr. Prosser James read his paper on

LOCAL ANÆSTHESIA.

He alluded to former efforts by himself, as well as others, to obtain substances which by local application would produce anæsthesia. Referring to Sir Erasmus Wilson's and Dr. Bill's discovery of the power of carbolic acid on the skin, he had followed up its use, largely diluted, on mucous membranes, and shown it to be a most valuable anodyne, as stated in his works on "Sore Throat," and on "Laryngoscopy." Further, he had employed it in combinations.

The sulpho-carbolates fail, but he had succeeded with simple carbolates of sodium and other bases, and now introduced them as valuable remedies, especially in the form of spray. Cocaine had then been introduced, and its place and power have become recognized. On account of its cost he had endeavored to find a substitute in caffeine, theine, theobromine, guaranine, etc. He had prepared a number of salts of these bases, forty or fifty of

which he exhibited last year in the annual museum, at Cardiff.

His method of ascertaining the effect of drugs on mucous membranes was to select a suitable patient, examine the larynx, then apply a solution and again examine at frequent intervals. In this way he had made many experiments, as, *e.g.*, those on expectorants, related in his work on "Respiratory Therapeutics," and which confirm those of Rossbach and Petronne on animals after section of the trachea. Referring to the action of cocaine, he had shown that it blanched the part to which it was applied, an observation simultaneously made by American observers. This effect he had sometimes utilized in local congestion, and he related a remarkable case in which highly vascular, warty growths had disappeared from the larynx after repeated applications of cocaine and sprays of a salt of caffeine. He then became desirous to determine whether any change in the local temperature could be proved to occur coincidently with the diminished vascularity. Of course the larynx could not be employed for such a research, and he was driven to experiment on the male urethra. A table of temperatures in this part was read, showing that in some instances a fall of fully 1° F. occurred when the urethra was rendered anæsthetic by cocaine. Similar, but less decisive, results were obtained by salts of caffeine and other alkaloids, and the author caused some amusement by remarking that his experiments, though so far decisive, were not very numerous, as patients with disease of the urethra did not fall in his line of practice; while, too, a healthy surface ought to be used, and gentlemen were not easily persuaded to submit to experiments on this part. He thought the facts noted worth reporting to the Section.

THE PRESIDENT thanked Dr. Prosser James on behalf of the Section for "his very interesting and valuable communication," and suggested that the discussion on it might very well be taken in connection with that on analgesics, which came next, if agreeable to the author and audience. This suggestion, being unanimously approved, was adopted, and the debate on analgesics began. The

DEBATE ON ANALGESICS

was introduced by Dr. Spender, in a paper rather too long for such a purpose, but full of interest. After some introduction, he said we come to close quarters with pain in neuralgia, calculus in the ureter, gall-stones, gout, etc., and patients demand relief at all cost. In such cases opium, or its alkaloid, still remained our chief agent. In supra-orbital pain, however, it was of little use, while ten grains of quinine, followed by a few doses of five grains, would cure. Gelsemium or chloral were not to be compared in these cases, especially when, as usually, there is a touch of malaria present. Again, in night pain in a syphilitic patient, analgesics of such a kind give only temporary relief, while iodides will, after a few doses, permanently remove the suffering. So salicin and arsenic are relatively indirect analgesics in other cases. Iron, in myalgia and neuralgia, has a similar relative value. Bromides only dispose to sleep, and in slight pain appear analgesic; but if the pain is sharp enough to baffle sleep, it defies bromides. They bring the system into a placid state disposing to sleep, but if this is disturbed the analgesic charm is broken. He referred to doses, and illustrated the subject by the different effect in various quantities of tartar-emetic, of opium, and morphia. Bleeding relieved vascular tension. Ergot raised motor force, and possibly sensation. He next urged that we economize our power by combining drugs, instancing morphia given with bromides, aconite with quinine, hemlock with several others, quinine with arsenic in herpes zoster, or with colchicum in gout, etc. He thought that, as surgeons have their instruments all in place, so as to find just what they want, so physicians should have a cupboard where all their analgesics could be seen in order at a glance, with hypodermatic syringes and other means of employing them. He concluded with a recognition of psychical analgesics, and the importance of recognizing not only the mental influence which by the sight of the dentist dismisses tooth-ache, but the spiritual comfort which the presence of a wise, christian physician may insensibly impart.

The PRESIDENT thanked Dr. Spender, and asked Dr. Brown-Séquard to follow.

DR. BROWN-SÉQUARD then gave an account of his discovery that a jet of carbonic acid gas, or of the vapor of chloroform, projected forcibly on the larynx, produced anæsthesia. Other agents will do it, but these are the best. After the larynx is thus anæsthetized the influence extends to other parts, and he has rendered animals insensitive to pain all over by this method. The effect lasts a long time—twenty-four or even thirty-six hours—and that without the least effect on consciousness or interference with any other function. He considered it due to an effect on the superior laryngeal nerve. When this nerve was divided, on one side there was no anæsthesia at all. He divided both and scarcely any effect occurred on either—only just enough to be attributed to the other less important nerves.

The higher the scale of the animal, the greater the effect. He had tried to apply it to man and had succeeded on himself, but the effect of projecting CO_2 on the laryngeal membrane is so exceedingly disagreeable, he had found no one else able to endure it for a long enough time, and, of course, precautions must be taken to prevent its inhalation. He was still, therefore, searching for an agent suitable for use on mankind. Galvanism of the nerve sometimes acted in the same way, but was very uncertain, and therefore useless.

Dr. Brown-Séquard's speech was listened to with the greatest attention, and he concluded amid most hearty plaudits.

PROFESSOR LIEBREICH, at the request of the President, next spoke. He drew a diagram on the blackboard to illustrate his views of the action of chloral and other ter-chlorine compounds, which, he said, began their action in the brain. If an agent next acted on the medulla and then on the heart when a toxic dose was given, life ceased when the heart no longer pulsated. If the heart preceded the cord, life could be maintained by artificial respiration.

He gave several illustrations, and showed their chemical relations to each other.

PROFESSOR LEECH agreed with much that Dr. Spender had said, but differed on dosage, and urged very small and very frequent doses.

DR. MACKEY, V.P., who had in the meantime assumed the chair, observed that the allotted time for the debate had nearly expired, and unless others desired to speak he would ask Dr. Prosser James and Dr. Spender to reply. Dr. Spender had been called away, and Dr. Prosser James expressed his great interest in the speeches and appreciation of the important statements which had been elicited, and regret that others did not join in the debate.

DR. MORTIMER GRANVILLE next read a paper on

THE RELIEF OF PAIN BY MECHANICAL VIBRATION OR PERCUSSION.

He no longer considered his method a novelty, as he had found that Mason Good spoke of percussion in his time as an established method of treating pain, and in early times the principle had been applied. His percuteur, however, which he exhibited, placed an easy and effectual method of using percussion in the hands of all.

MR. JESSUP read a paper on

THE EFFECTS OF COCAINE IN [illegible] EYE,

in which he pointed out that it is sometimes injurious. It might, he declared, produce glaucoma, and he found it increase exophthalmos.

Dr. Mackey, V.P., said he had used cocaine in a case of exophthalmos for the relief of pain, for which it was very effectual, and although it had been used some time no mischief had been noticed, and he asked Mr. Jessup whether, as an ophthalmic surgeon, he would advise its discontinuance? The case was not extreme.

Mr. Jessup had only used it in severe cases, but his experience showed it increased the disease, so that he could not advise it to be continued.

Dr. Stephen Mackenzie read a paper

ON CANNABIS INDICA IN CERTAIN HEADACHES.

He lauded the drug, but said it must be continued for months in full doses, with alteratives and aperients. It was in continuous, dull, heavy headaches he recommended it.

Dr. Mackey said that the late Dr. Seguin, of New York, had strongly recommended this drug, but chiefly in intermittent headaches. Dr. Mackey had followed this practice with success, and often in children, and he found Brighton children suffered much from these intermittent headaches. It was only in giving it in continuous cases that this paper differed from Dr. Seguin's practice, and curiously, the author of it used the cannabis in the same doses and the same combinations as Dr. Seguin.

No other member wishing to speak, Dr. Mackenzie replied that he was acquainted with Seguin's views, and the drug was recommended in all text-books, but not in these peculiar continuous cases. The time having now expired the Section adjourned.

Dr. W. H. Stone exhibited in this Section the apparatus which he had used at his recent Lumleian lectures, and during the day, in an adjoining room, he gave demonstrations from time to time to interested knots of listeners.

(To be continued.)

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

Tenth Annual Session, held at Indian Harbor Hotel, Greenwich, Conn., August 25, 26, and 27, 1886.

WEDNESDAY, AUGUST 25TH—FIRST DAY—MORNING SESSION.

The President, Dr. Edward Wigglesworth, of Boston, called the Society to order at ten o'clock. The first business was the reading of the President's address.

Gentlemen: Ten years ago, at Philadelphia, I had the honor of calling to order the first public meeting for the organization of this Association. Our specialty for the first time received national acknowledgment. Our guerilla warfare was over, and our subsequent record has been one of unbroken successive victories over bigotry, error, and ignorance.

But the day of paladins is past, and our ranks will admit more recruits. There are still remaining opportunities for more extended instruction of students in medical schools, while the lack of hospital facilities for the proper clinical treatment of diseases of the skin is a standing shame and disgrace to our municipal authorities, our hospital boards, and to the medical profession itself. Some progress has, however, been made. New York has now a special hospital for skin diseases, besides two wards in the Charity Hospital, and Philadelphia has special clinics with beds at three different institutions.

About twice as many cases of diseases of the skin are now annually treated by specialists as there were ten years ago.

The contributions to American dermatological literature during the past decade include the best treatises, hand-books, and atlases, the only periodicals, and some of the best monographs of the time in the English language.

Our sole local organization, the New York Dermatological Society, is as active as ever, and the good work which it has already done is constantly increasing.

Other objects of the foundation of our Association have been by no means neglected during the past ten years. There exists to-day a harmony and good feeling among us which, but for the personal acquaintanceship resulting from the formation of this Association, never would have existed. We have come into better accord as to the "Nature and Treatment of Skin Diseases." Our increased membership proves that our Association is "held as a place of aspiration," and it has consistently required "independent work in our department" as the essential preliminary step toward the acquisition of such membership. The systematic work of our Standing Committee upon Statistics has already furnished valuable data for comparison, as well as a series of excellent reports upon "Leprosy in America." Concerted official effort has done much, and will do more, to repress the rank luxuriance of growth of dermatological nomenclature, and to furnish a "uniform and simple system."

While much has been accomplished, much still remains to be done. The idea of specialism, already rooted, is to be nurtured and trained in the minds of the profession and of the public, and the practical development, socially, of our specialty itself, is to be elaborated in many minor details. The pioneer must no longer prove a martyr. A knowledge of the weaker side of human nature, useful for selfish, financial ends, must no longer be allowed to usurp the province of exact scientific acquaintance with disease, inuring to the benefit of our race. The "elaborate division of labor" is "as useful and successful in a learned profession as it is in the mechanic arts," for it is merely a relative question of height of standard. Specialism substitutes quality for quantity, which substitution is the essential characteristic of the civilized man as distinguished from the savage; while the rapidity of such substitution gauges the progress of civilization itself. Medicine is merely that complex whole which results from the combination of all its component parts, and their individual advancement is the criterion of its own progress.

Science is only exact knowledge. Medicine is that knowledge specially directed to the physical welfare of mankind, and specialism is only that further subdivision rendered necessary by the very various parts composing the individual, and possible by the extension of our opportunities for studying these parts due to increase of mechanical means for enlargement of the fields of our hitherto unaided senses. No one can to-day "take all knowledge to be his province." Science does not culminate in a Jack-of-all-trades, least of all in one whose conscience has become anæsthetized by custom, who confounds his own limitations with the "limitations of human understanding," and his own ignorance with "the immaturity of medical therapeutics." The specialist builds his own boundary wall, and cannot, if he would, poach upon the preserves of others. He "distinguishes what he can do from what he cannot," thus filling the old definition of the best physician. He cannot maltreat a patient, and when compelled to confess ignorance and seek superior wisdom, charge the wronged sufferer another and still higher fee for a "consultation," which is, in reality, a confession. It has been sarcastically said that "the sole duty nowadays of the family doctor is to decide what specialist shall be summoned." It certainly is his duty, and a very important one as a man of honor, to decide whether anyone, and if so, who, can probably accomplish that wherein he admits that he himself has failed. Unfortunately, many know so little that they are even ignorant of how much is known by others; but in many respects the specialist has already raised the average standard of requirement for general practice to such an extent that much of the old routine practice of physicians, who treated their patients for the very diseases for which they referred members of their own families to the specialist, has now become punishable malpraxis. But the general practitioner has his revenge in opposing as unnecessary the hospital appointment, and even the

private practice, of the very specialist to whom he himself flees as "a very present help in time of trouble."

We are told that "the human body is made up of parts and functions so thoroughly interdependent that it cannot be parcelled out into defined and isolated regions." It can, and it cannot. What scientist divides a country into square miles and attempts to become thoroughly conversant with every atom existing in each of those miles? The special divisions of study are rather the flora, the fauna, the geological strata, etc., though all these may pervade identically every mile of the region. If regional surgery is possible, then specialties are certainly not contra-indicated. We hear of "appalling pathological conglomerates," due to lack of proper "general medical treatment." Not only "conglomerates," but often single lesions, are very variously diagnosticated by different general physicians, and the "conglomerates" are usually merely the aggregated effects of original causes which might have been obviated by proper investigation in due season on the part of suitable specialists.

The aforetime "consulting physician" meant one who in addition to his general acquirements knew more about some particular thing than anyone else. We may be sure that his general acquirements had to pay the penalty. To-day we honestly admit this, and, renouncing the practice obtainable by general acquirements, keep to that particular thing of which we know more than others. No one has mental ability enough at the present time to add to the greatly extended knowledge necessary to the general physician the intensified fundamental acquaintance with detail needed by the specialist. Life is too short for the ablest intelligence to exhaust even any one specialty. The physician may, like Newton, "think the thoughts of God after him," but the thoughts of the infinite upon the smallest molecule of matter call for more than the limits of a finite existence. The true consulting physician of to-day is the specialist, and he should therefore receive this title at the hospitals with which he is connected, while those ex-physicians, called consulting, but never consulted, should receive their true and proper title of Emeriti.

But enough of the "idea of specialism." The public will in time appreciate the absurdity of being content with inferior results in one branch of medicine, because, forsooth, there are so many others in which their medical adviser is equally or more at home. It will reason rather that he who "insists upon doing the work of ten men manifests a quality of mind which we can only call arrogance, and which challenges for his work severe criticism." Versatility will not atone for crude and imperfect work any more than will lack of time, hurry of life, keenness of competition, or financial necessity, and it is merely brazen self-assertion which delights "not so much in doing the thing well as in showing how well he can do it."

Believing in the ultimate achievement of all possibilities, and in the progress of truth, I have no doubt as to the future of specialism if we are honest and earnest. Not infinite omniscience, but infinite morality, is the duty of the specialist, and this conscientiously carried out will blunt the sharpest dart of the hostile general practitioner. While visions of what yet remains to be accomplished might well lead us almost to despair, a mere glance at the generally prevailing ignorance on the part of both physicians and their patients shows conclusively that we and our work are imperatively demanded.

Dr. J. C. White, of Boston, held that more exact data must be obtained before we can regard these affections as a necessary sequel of syphilis, and as anything more than accidental occurrences. While there is nothing *à priori* against a casual relation existing between these conditions and syphilis, such relation has not been proved. The early roseolous exanthematous condition of the skin in syphilis is of sufficiently frequent occurrence to be looked upon as a distinct feature of syphilis. This is wholly unlike the rare forms of dermatitis which have been described to-day.

Dr. G. H. Tilden, of Boston, thought that in the present state of our knowledge it would be more philosophical to consider the appearances described as accidental rather than as dependent upon the specific disease.

RUBELLA, OR ROTHELN,

by Dr. I. E. Atkinson, of Baltimore, consisted of a thorough *résumé* of the literature of the subject, and gave an extended account of its symptoms, diagnosis, etc. The disease was regarded as distinct from measles and scarlet fever. Swelling of the lymphatic glands is a peculiar and marked symptom. This swelling is painful, but does not pass on to suppuration. In many cases fever is absent. The eruption first appears on the forehead and face, and in the course of a few hours spreads to other parts of the body. Complications and sequelæ are not unknown, the most common being bronchitis, pneumonia, and gastro-intestinal disorders.

The Speaker suggested that rubella be accepted as the proper title of this disease, and that it might be known in popular language as epidemic roseola.

Correspondence.

OUR PARIS LETTER.

[From our special Correspondent.]

THE TREATMENT OF PHTHISIS BY RECTAL MEDICATION—INFECTIOUS CHARACTER OF ERYSIPELAS—RESULTS OF OSTEOTOMY FOR CLUB-FOOT—JUGULATION OF TYPHOID FEVER—VACCINATION AND REVACCINATION—M. CHEVREUL.

PARIS, August 14, 1886.

At a recent meeting of the Academy of Sciences Dr. Bergeon brought to notice the advantages of a therapeutical method based on this principle, established by Claude Bernard, to wit, that the introduction through the rectum of substances, even when toxic, does not present any danger so long as pulmonary elimination is not interfered with. The author employed this method in several maladies, and particularly in pulmonary phthisis, and, after a certain number of trials, he gives the preference to sulphurous mineral waters. A current of from 4 to 5 litres of carbonic acid gas passing through from 250 to 500 grammes of sulphurous mineral water is introduced into the rectum twice in the twenty-four hours. A few days after the employment of this procedure Dr. Bergeon noticed: 1. A diminution, approaching almost to total suppression, of the cough. 2. A profound modification in quality as well as in quantity of the expectoration. 3. Suppression of the sweats. 4. Improvement of the general state, and that not only in phthisis at its commencement, but in its confirmed state. Auscultation, daily practised, permitted the doctor to verify the progressive disappearance of the moist râles.

In his inaugural thesis for the doctorate, Dr. Blaise chose for his subject "De l'Érésipèle Infectieux." According to the author, all the symptoms presented by erysipelas tend to demonstrate its infectious character. To the contagion, fever, shivering, the eruption, the visceral lesions, must be added, as proof of this infection, the hemorrhages. The hemorrhages which are met with in erysipelas are of diverse natures—hemorrhages from the mucous membranes, subcutaneous hemorrhages, deep sanguineous collections. The subcutaneous hemorrhages may show themselves under the form of ecchymoses, petechiæ, or under the form of purpura. The latter may

remain localized, or it may become generalized. It is transitory, appears at places where the erysipelatous eruption had just left, and may reappear at different times. It appears to come on after the eruption or during convalescence. The hemorrhages from the mucous membranes consist of frequent epistaxes, which are sometimes so profuse as to place the life of the patient in danger.

At a recent meeting of the Surgical Society of Paris, Professor Verneuil read a paper on "The Results of Osteotomy for Club-foot." His mode of operation consisted in taking away in succession the astragalus, the cuboid, the scaphoid, and the anterior half of the os calcis, until he is able to bring the foot in a line with the leg. He does not, however, attempt to fix the foot in position until the wound is in a fair way of being healed, and upon this he lays stress. Dr. Lucas Championnière, on the contrary, tries to obtain primary union of the wound, so that apparatus to correct the deformity may be applied as speedily as possible; while Professor Verneuil thinks that suppuration is useful in that it gives rise to a large mass of new-granulation tissue.

Professor Pécholier, of the Faculty of Montpellier, made a communication at the meeting of the Paris Academy of Medicine, last week, on the abortive treatment, or what he terms the "jugulation," of typhoid fever, which consists of administering the sulphate of quinine in doses of from one gramme to one gramme twenty centigrammes per day from the earliest recognition of the symptoms. During the first few days of the attack, or when there is much disturbance of the heart's action, he administers twenty centigrammes of digitalis, in combination with the sulphate of quinine, per day. When the body temperature is unusually high, foot-baths are added to the treatment, especially when any congestive phenomena are observed in the head or other viscera. By this treatment the disease, according to M. Pécholier, is "jugulated" in from thirteen to fifteen days; in support of which the doctor cites sixty-four consecutive cases which came under his own observation, and among which not a single death occurred.

According to a report furnished at the same meeting by Dr. Blot, director of gratuitous vaccination at the Academy of Medicine, where human lymph alone is employed, there have been, during the last six years, 19,000 vaccinations, and 5,336 revaccinations performed; 70,000 squares of glass, 16,000 tubes containing vaccine lymph, and 29,000 lancets tipped with the same, have been sent out in that time. Thus there are from 3,000 to 4,000 vaccinations and 1,000 revaccinations per year. As regards results, the successes by arm to arm vaccination amount to ninety-nine per cent., with the lymph in tubes from eighty-five to ninety per cent. This report was furnished at the requisition of the Minister of Public Instruction, in forwarding which the Academy expressed a wish that centres for vaccination should be organized all over France, so as to be within the reach of all. They should be placed particularly in the large seaport towns.

On the 31st of this month, the venerable M. Chevreul attains his 100th year, on which occasion a grand popular fête is to be organized in his honor. The greater number of his colleagues of the Institute have promised to take part in the celebration, which is fixed for September 1st. The fête is to take place at the Museum of Natural History, which has been chosen for several reasons. In the first place it was done to spare him as much fatigue as possible, being near to his own residence; and it has also been considered that the illustrious academician has spent nearly all his life at the Museum, where he entered in 1810, as chemical assistant, since which time he has never left it. In 1830, he succeeded his master, Vauquelin. Forty years later, being director of the Museum during the siege and bombardment of Paris, he managed to save from complete ruin the magnificent collection confided to his care.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 22 to August 28, 1886.

WOODHULL, A. A., Major and Surgeon. Granted leave of absence for fourteen days, to take effect on or about September 1, 1886. S. O. 197, A. G. O., August 25, 1886.

TAYLOR, M. K., Major and Surgeon. Leave extended one month. S. O. 195, A. G. O., August 23, 1886.

LAUDERDALE, J. V., Captain and Assistant Surgeon. Granted leave of absence for two months, with permission to apply for one month's extension when his services can be spared. S. O. 195, A. G. O., August 23, 1886.

GANDY, CHARLES M., First Lieutenant and Assistant Surgeon. On expiration of his present leave of absence relieved from duty in the Department of the East, and assigned to duty in the Department of Texas. S. O. 195, A. G. O., August 23, 1886.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau. Health Department, for the week ending August 28, 1886:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	27	6
Scarlet fever	14	5
Cerebro-spinal meningitis	0	0
Measles	27	11
Diphtheria	45	23
Small pox	0	0

UNIVERSITY OF LONDON EXAMINATIONS.—The pressure brought upon the University of London to induce that institution to hold its examinations more frequently has been partially successful. It is now announced that not only the Preliminary Scientific, but also the Intermediate Examination for the M.B. degree will be held twice a year. Candidates in future will also have to choose between the pass and the honors examinations at the latter as well as at the former examination. This is a unique departure in medical examinations. It means that candidates who wish for honors will, in future, have to go direct for the honors examination—in their honors subject or subjects—while taking the pass papers in the rest of the examination. At present a candidate can go in for a "pass," and then please himself afterward about going in for honors.

THE LATE DR. MOXON.—Our London correspondent sends us the following interesting account of Dr. Moxon: "In the person of Dr. Moxon London loses one of its ablest, most original, and highly esteemed physicians. Dr. Moxon was found dead in his chair at an early hour of the morning. He was only fifty. At the time of his death he was one of the full physicians to Guy's Hospital, having previously served the subordinate offices with credit and distinction. Dr. Moxon received his medical education at Guy's Hospital, and graduated with honors at the University of London. Both at Guy's and at St. Bartholomew's it is well understood that only on their own alumni will hospital appointments be conferred. At the latter hospital I believe the rule is absolute. At Guy's it has at any rate been very consistently acted upon, and to such an extent that it is not usual for outsiders to apply. The last vacant

assistant physiciancy was, it is true, thrown open, but it was nevertheless bestowed on a Guy's man. Dr. Moxon was more fortunate than many of his contemporaries in getting his appointment at a comparatively early age. At the older hospitals—notably at Bartholomew's—the tendency has been to hedge them about so strictly that a man may be nearly forty before he becomes assistant physician. Dr. Moxon excelled both as a writer, a teacher, and a practical physician. He was an early worker in the field of visceral syphilis, and wrote a paper on the subject in 'Guy's Hospital Reports' nearly twenty years ago. He will perhaps be best remembered by his published 'Lectures on Pathological Anatomy,' of which he was author jointly with Dr. Wilks. This work at once obtained an acknowledged position. With no pretence of being exhaustive, and no attempt to give all the minutiæ of pathological histology, it still remains unrivalled as a faithful exponent of naked-eye morbid anatomy, and that, too, in a style not devoid of literary grace. In literature and controversy Dr. Moxon was what may be called a free lance. He apparently delighted in the unconventional, and would say what he thought, whether popular or otherwise. He once gave a clinical lecture in which he expressed the wish that he could compel all his pupils to study heart diseases in the wards for three months without using a stethoscope, but simply paying attention to the general symptoms. His lively but good-humored criticism of Dr. Bristowe's definition of fever as 'that abstract condition which is common to all so-called "febrile disorders," and the presence of which gives them their claim to that designation,' is still fresh in our memories, and the pungency of Dr. Moxon's satire was not much detracted from when it was pointed out that he had only quoted one sentence in Dr. Bristowe's definition. Dr. Moxon took a great interest in the question of degrees for London students, but was anxious for the present university in London to retain its position. He was, however, wishful to see its influence extended, and the publication of a colonial pass-list of one of its examinations drew from him a sarcastic taunt as to the university concerning itself with primary education in the Mauritius. While, however, he will still live to the many through his published writings, he will be still more vividly remembered by those who had the pleasure and privilege of his personal acquaintance. As a clinical teacher, nothing was more remarkable than the way in which he always found something fresh to say about his cases. If he saw the same case several times a week for weeks, he would make it teach something on every successive visit. He was so unconventional, also, that it sometimes seemed as if his fluency in speech was running away with him and making him say what he did not mean, but even when on the verge of the absurd he would make what he was saying teach something and show that, however apparently purposeless his speech had been, he had not for a moment lost sight of the point before him."

Agnew's Surgery is now being translated into Japanese by Dr. Toynbe. It is to be published in seven volumes, at a cost to subscribers of seven yen, about six dollars.

Pollution of Thames Water.—Coincidently with the advent of real summer weather and the annual increase in diarrhœa cases comes the usual scare about the condition of the Thames. A new danger exists, we are told, in the regattas held on the Upper Thames. These attract a large concourse of yachts and house-boats, the sewage and refuse from which is mostly thrown overboard and comes down to pollute the intake of the water companies. How many germs may thus be introduced into the water we drink it is impossible to say. Meanwhile it is but a very poor consolation to be told by Messrs. Crookes, Tidy, and Odling that bacilli will not live long in pure water, as that of our metropolitan river is very far indeed from being pure.

Ninth International Medical Congress. The Ninth International Medical Congress will assemble in the city of Washington, the capital of the United States, on Monday, September 5, 1887, at twelve o'clock noon, in accordance with the arrangements made at Copenhagen in August, 1884.

Patrons.—The President of the United States, the Hon. Grover Cleveland; the Secretary of State, the Hon. Thomas F. Bayard; the President of the Senate of the United States, the Hon. John Sherman; the Speaker of the House of Representatives of the United States, the Hon. John G. Carlisle.

President of the Congress and Chairman of the Council: Nathan S. Davis, M.D., LL.D., Professor of the Principles and Practice of Medicine and of Clinical Medicine, Chicago Medical College, and of Mercy Hospital, Chicago, Ill.

Vice-Presidents (as far as appointed): McCall Anderson, M.D., London, England; Mr. Thomas Annandale, Professor of Clinical Surgery, Edinburgh University, Edinburgh, Scotland; Professor Dujardin-Beaumetz, M.D., Paris, France; Cuthbert Hilton Golding Bird, M.D., Professor of Physiology, Guy's Hospital, London, England; Professor Carl Braun, M.D., Vienna, Austria; William Brodie, M.D., Emeritus Professor of Principles and Practice of Medicine and Clinical Medicine, Detroit College of Medicine, Detroit, Mich.; W. W. Dawson, M.D., Professor of Surgery and Clinical Surgery, Medical College of Ohio, Cincinnati, O.; Thomas M. Dolan, M.D., Halifax, England; F. R. Frazer, M.D., Professor of Materia Medica and Therapeutics, University of Edinburgh, Edinburgh, Scotland; J. A. Grant, M.D., Ottawa, Canada; J. A. S. Grant, M.D., Cairo, Egypt; A. L. S. Gusseraw, M.D., Professor of Obstetrics, Berlin, Prussia; Dr. Hans Ritter von Hebra, Vienna, Austria; Dr. E. Klein, London, England; Mons. le Baron H. Larrey, Paris, France; Sir William MacCormac, Surgeon St. Thomas' Hospital, London, England; Mr. George B. Macleod, Professor of Surgery, Glasgow, Scotland; John S. McGrew, M.D., Honolulu, Hawaiian Islands; E. M. Moore, M.D., LL.D., Rochester, N. Y.; Professor Von Monseil, Bonn, Prussia; Dr. Muller, Berlin, Prussia; William Murrell, M.D., London, England; Charles D. F. Phillips, M.D., M.R.C.S., late Lecturer on Materia Medica and Therapeutics, Westminster Hospital, London, England; Mr. Richard Quain, Professor of Anatomy, London, England; Tobias G. Richardson, M.D., Professor of General and Clinical Surgery, Medical Department, Tulane University, New Orleans, La.; Mons. P. Ricord, Paris, France: Professor John Burdon Sanderson, M.D., London, England; Lewis A. Sayre, M.D., Professor of Orthopædic and Clinical Surgery, Bellevue Hospital Medical College, New York; Dr. Mariano Semmola, Professor of Experimental Therapeutics, University of Naples, Italy; Dr. Leopold Servais, Antwerp, Belgium; J. M. Toner, M.D., Washington, D. C.; Dr. P. G. Unna, Hamburg, Germany; Professor F. Winckel, Dresden, Saxony; the President of the American Medical Association; the Surgeon-General of the United States Army; the Surgeon-General of the United States Navy.

Secretary-General: John B. Hamilton, M.D., Supervising Surgeon-General of the United States Marine Hospital Service; Professor of Surgery, Georgetown University, D. C.; Professor of Surgery, Chicago Polyclinic.

Treasurer: E. S. F. Arnold, M.D., M.R.C.S., Newport, R. I.

Chairman of the Finance Committee: Richard J. Dunglison, M.D., Philadelphia, Pa.

Chairman of the Executive Committee: Henry H. Smith, M.D., LL.D., Emeritus Professor of Surgery in the University of Pennsylvania, Philadelphia, Pa.

Chairman of the Committee of Arrangements: A. Y. P. Garnett, M.D., Emeritus Professor of Clinical Medicine, Columbia University, Washington, D.C.

The congress will consist of such members of the reg-

ular medical profession as shall have registered and taken out their ticket of admission, and of such other scientific men as the Executive Committee of the congress shall deem it desirable to admit. The books for the registration of members will be open from 9 A.M. to 5 P.M., on Thursday, September 1, 1887, and on each subsequent day during the session, under the charge of the "Reception Committee." Any member desiring to anticipate this registration can apply by letter to the Secretary-General and forward his dues, with his address in full, when a receipt will be returned. The dues of membership for residents of the United States will be ten dollars ($10.00). There will be no dues for members residing in other countries. Each member will be entitled to receive a copy of the "transactions" of the congress, when published by Executive Committee. The general sessions of the congress will be devoted to the transaction of business, and addresses and communications of general scientific interest by members appointed by Executive Committee. A printed "programme" of the sessions will be presented to each member on registering. A printed "order of business" for each day will also be issued. The work of the various sections will be directed by the president of the section, and the order will be published in a daily programme for each section. Questions and topics that have been agreed on for discussion in the sections shall be introduced by members previously designated by the titular officers of each section. Members who shall have been appointed to open discussions shall present to the secretaries of the section, in advance, statements of the conclusions which they have formed as a basis for the debate. Brief abstracts of papers to be read in the sections shall be forwarded to the secretaries of the proper sections, on or before April 30, 1887. These abstracts shall be treated as confidential communications, and shall not be published before the meeting of the congress. Papers related to topics not included in the list of subjects proposed by the officers of the sections may be accepted after April 30, 1887, and any member wishing to introduce a topic not on the regular lists of subjects for discussion shall give notice of the same to the Secretary-General, at least twenty-one days before the opening of the congress. The titular officers of each section shall decide as to the acceptance of such proposed communications, and the time for their presentation. No communication shall be received which has been already published or read before a society. The official languages of the congress shall be English, French, and German. Each paper or address shall be printed in the "transactions" in the language in which each is to be delivered. All discussions shall be printed in English. The officers of the congress and the officers of the sections, including all foreign officers, will be nominated to the congress by the Executive Committee, at the opening of the first session. A partial list of the officers to be nominated (except the members of council of the different sections, the list of whom is at present imperfect) is offered herewith. The Executive Committee cordially invites members of the regular medical profession, and men eminent in the sciences collateral to medicine, in all countries, to participate, in person or by papers, in the work of this great humanitarian assembly. Communications relating to appointments for papers to be read in the congress should be addressed to Dr. John B. Hamilton, Secretary-General of the Ninth International Medical Congress, Washington, D. C. All questions or communications connected with the business of the Executive Committee should be addressed to Dr. Henry H. Smith, Chairman of the Executive Committee of the Ninth International Medical Congress, Philadelphia, Pa. Gentlemen named in any position in the congress are requested to notify the Chairman of the Executive Committee, as soon as practicable, of any error in the name, title, or address in this circular. Ladies in attendance with members of the congress, and those invited by the "Reception Committee," may attend the general sessions of the congress when introduced by a member. They will also be invited to attend the social receptions. The Executive Committee reserves the right to invite distinguished persons to any or all the meetings of the congress. The attendance of medical students and others interested in the work of the various sections, or in the general addresses delivered in the congress, will be permitted, on the recommendation of the Secretary-General or the officers of a section, on their taking out from the Registration Committee a general ticket of admission, fee one dollar ($1.00); but such persons cannot take part in the proceedings. All communications and questions relating to the special business of any section must be addressed to the President or one of the Secretaries of that section. As many details of the congress and numerous appointments of officers are yet to be completed, other circulars will be issued from time to time, as circumstances may demand. The following is the list, as at present completed:

Executive Committee of the Congress.—Drs. Henry H. Smith, Chairman; N. S. Davis, John B. Hamilton, E. S. F. Arnold, Richard J. Dunglison, Secretary; Abram B. Arnold, William T. Briggs, DeLaskie Miller, James F. Harrison, F. H. Terrill, William H. Pancoast, John H. Callender, Alonzo B. Palmer, J. Lewis Smith, E. Williams, S. J. Jones, William H. Daly, A. R. Robinson, Joseph Jones, Albert L. Gihon, John P. Gray, Jonathan Taft, Frederick S. Dennis, A. Y. P. Garnett.

Presidents of Sections.—General Medicine: Abram B. Arnold, Professor of Clinical Medicine, College of Physicians and Surgeons, Baltimore, Md. General Surgery: William T. Briggs, Professor of Surgery, University of Nashville, Nashville, Tenn. Military and Naval Surgery and Medicine: Henry H. Smith, Emeritus Professor of Surgery, University of Pennsylvania, and formerly Surgeon-General of Pennsylvania, Philadelphia, Pa. Obstetrics: DeLaskie Miller, Professor of Obstetrics, Rush Medical College, Chicago, Ill. Gynæcology: James F. Harrison, Professor of Obstetrics, etc., University of Virginia, Va. Therapeutics and Materia Medica: F. H. Terrill, Professor of Therapeutics, University of California, San Francisco, Cal. Anatomy: William H. Pancoast, Professor of General, Descriptive, and Surgical Anatomy, Medico-Chirurgical College, Philadelphia, Pa. Physiology: John H. Callender, Professor of Physiology and Psychology, University of Nashville, Nashville, Tenn. Pathology: Alonzo B. Palmer, Professor of Pathology, University of Michigan, Ann Arbor, Mich. Diseases of Children: J. Lewis Smith, Professor of the Diseases of Children, Bellevue Hospital Medical College, New York. Ophthalmology: E. Williams, Professor of Ophthalmology, Miami Medical College, Cincinnati, O. Otology: S. J. Jones, Professor of Ophthalmology and Otology, Chicago Medical College, Chicago, Ill. Laryngology: William H. Daly, Pittsburg, Pa. Dermatology and Syphilis: A. R. Robinson, Professor of Dermatology, New York Polyclinic, and of Histology and Pathological Anatomy, Woman's Medical College of the New York Infirmary, New York. Public and International Hygiene: Joseph Jones, Professor of Chemistry and Clinical Medicine, Tulane University; Ex-President Board of Health, New Orleans, La. Medical Climatology and Demography: Albert L. Gihon, Medical Director, United States Navy. Psychological Medicine and Nervous Diseases: John P. Gray, Professor of Psychological Medicine and Medical Jurisprudence, Bellevue Hospital Medical College, Utica, N. Y. Dental and Oral Surgery: Jonathan Taft, Professor of Dental and Oral Surgery, University of Michigan, Ann Arbor, Mich., Cincinnati, O.

Vice-Presidents of Sections.—General Medicine: W. W. Cleaver, Kentucky; J. A. Octerloney, Kentucky; P. G. Robinson, Missouri; Thomas F. Rochester, New York; Preston B. Scott, Kentucky. General Surgery: Moses Gunn, Illinois; J. W. Hamilton, Ohio; W. H.

Hingston, Canada; James M. Holloway, Kentucky; J. C. Hutchinson, New York; N. S. Lincoln, District of Columbia; Donald MacLean, Michigan; Donald Macrea, Iowa; M. Storrs, Connecticut. Military and Naval Surgery and Medicine: C. J. Cleborne, United States Navy; E. H. Gregory, Missouri; Frank H. Hamilton, New York; W. T. Hord, United States Navy; Frederick Hyde, New York; G. L. Porter, Connecticut; William E. Taylor, United States Navy; B. A. Watson, New Jersey. Obstetrics: Gustav Braun, Austria; P. Budia, France; J. Galabin, England; John Goodman, Kentucky; W. M. Knapp, Nebraska; R. L. Sibbet, Pennsylvania; Isaac E. Taylor, New York. Gynæcology: N. Bozeman, New York; Henry O. Marcy, Massachusetts; T. A. Reamy, Ohio; H. R. Storer, Rhode Island. Therapeutics and Materia Medica: Henry M. Field, New Hampshire; Albert Fricke, Pennsylvania; George Gray, Ireland. Anatomy: C. W. Kelly, Kentucky; Samuel Logan, Louisiana. Physiology. Pathology: Andrew Fleming, Pennsylvania; J. B. Johnston, Missouri; Henry F. Lyster, Michigan. Diseases of Children: William B. Atkinson, Pennsylvania; William G. Booker, Maryland; Cadet de Gassicourt, France; Edward Hunoch, Prussia; Adoniram B. Judson, New York; J. P. Owen, Massachusetts; Eustace Smith, England; Charles West, England; Joseph E. Winters, New York. Ophthalmology: A. W. Calhoun, Georgia; J. J. Chisholm, Maryland; P. D. Keyser, Pennsylvania; Dudley S. Reynolds, Kentucky. Otology. Laryngology: M. F. Coomes, Kentucky. Dermatology and Syphilis: James M. Keller, Arkansas; John V. Shoemaker, Pennsylvania. Public and International Hygiene: A. Nelson Bell, New York; John Berrien Lindsley, Tennessee; J. N. McCormack, Kentucky; J. F. Y. Paine, Galveston, Tex.; Benjamin W. Richardson, England; John Simon, England; J. W. Thudichum, England. Medical Climatology and Demography: Dr. A. Chervin, Paris, France; Traill Green, Pennsylvania; John H. Hollister, Illinois. Psychological Medicine: Julius Althaus, England; R. H. Chase, Pennsylvania; Eugene Grissom, North Carolina; John C. Hall, Pennsylvania; P. A. Hooper, Arkansas; J. S. Jewell, Illinois; S. S. Schultz, Pennsylvania. Dental and Oral Surgery: W. W. Allport, Illinois; S. W. Dennis, California; C. L. Ford, Michigan; H. L. McKellops, Missouri; A. T. Metcalf, Michigan; W. H. Morgan, Tennessee; A. L. Northrop, New York.

Secretaries.—General Medicine: J. W. Chambers, Baltimore, Md. General Surgery: Dudley P. Allen, Cleveland, O.; Carl Mayde, Germany; J. R. Weist, Richmond, Ind.; A. H. Wilson, South Boston, Mass. Military and Naval Surgery and Medicine: J. McF. Gaston, Atlanta, Ga.; E. A. Wood, Pittsburg, Pa. Obstetrics: A. Charpentier, Paris, France; T. Felsenreich, Vienna, Austria; W. W. Jaggard, Chicago, Ill.; John Williams, London, England. Gynæcology: Ernest W. Cushing, Boston, Mass. Therapeutics: Frank Woodbury, Philadelphia, Pa. Anatomy: Henry Morris, Philadelphia, Pa. Physiology: R. W. Bishop, Chicago, Ill. Pathology: H. M. Biggs, New York; I. N. Himes, Cleveland, O. Diseases of Children. Ophthalmology: S. C. Ayres, Cincinnati, O. Otology: S. O. Richey, Washington, D. C. Laryngology: William Porter, St. Louis, Mo. Dermatology: W. T. Corlett, Cleveland, O.; F. E. Daniel, Austin, Tex. Public and International Hygiene: George H. Rohe, Baltimore, Md.; Walter Wyman, United States Marine Hospital Service, New York. Climatology and Demography: Charles Denison, Denver, Col.; James F. Todd, Chicago, Ill. Psychological Medicine: E. D. Ferguson, Troy, N. Y.; E. Landolt (Berlin, Prussia), Paris, France. Dental and Oral Surgery: Edward A. Bogue, New York; S. F. Rehwinkle, Chillicothe, O.

Committee of Arrangements, Washington, D. C.—Chairman, A. Y. P. Garnett; Vice-Chairman, J. M. Toner; Secretary, C. H. A. Kleinschmidt; Treasurer, D. C. Patterson.

Executive Committee.—A. Y. P. Garnett, J. M. Toner, N. S. Lincoln, C. H. A. Kleinschmidt; Surgeon-General F. M. Gunnell, United States Navy; Surgeon-General Robert Murray, United States Army; Supervising Surgeon-General J. B. Hamilton, United States Marine Hospital Service; Chief Medical Purveyor J. H. Baxter, United States Army. Committee on Congressional Legislation: Dr. A. Y. P. Garnett, Chairman. Committee on Finance: Dr. G. L. Magruder, Chairman. Committee on Printing: Dr. J. B. Hamilton, Chairman. Committee on Reception: Dr. J. M. Toner, Chairman. Committee on Entertainments: Dr. N. S. Lincoln, Chairman. Committee on Transportation: Dr. J. W. H. Lovejoy, Chairman. Committee on Place of Meeting for Congress and Sections: Dr. D. C. Patterson, Chairman.

By Order of the Executive Committee of the Congress.

DR. HENRY H. SMITH, Chairman.
DR. RICHARD J. DUNGLISON, Secretary.

THE DEATHS IN INDIA FROM SNAKES AND WILD BEASTS were, in 1885, from snake-bites, 1,066; from wild beasts, 110.

A DEFENCE OF AMERICAN MEDICAL SCHOOLS.—Dr. H. W. Jones, M.A., an American resident of England, writes to *The Lancet:* "It is by no means uninteresting to a medical man 'abroad' to observe his own country and its institutions through the eyes of foreign authorities. And while we must confess to much that was questionable in the past, it appears at present that the case of medical education in the United States is hardly put with fulness—if, indeed, with fairness. As the effete doctrines of the early Church yet serve as the sceptic's best weapons, so now do the allegations which I here rehearsed rise against the 'American system.' We are charged with 'inadequate preparation,' opening the schools to crude and undisciplined minds; with a 'too short and narrow curriculum,' giving insufficient and unbalanced foundation for so serious and important a superstructure; with 'poverty of clinical advantages,' committing students to an unpractical, and, therefore, untrue, view of their future duties; with 'the full degree conferred by any of the too numerous colleges after such a course.' Truly a sad catalogue of errors, if applicable now and generally to the institutions of any country. But a knowledge of all the circumstances will insure material alteration in the scope of these charges, and a much closer approximation to the truth. Though I write without statistics at hand, and only from a general acquaintance with the facts acquired by long professional observation, I venture to state that more than half the American graduates have for many years gone out from the three great medical centres, New York, Philadelphia, and Boston, whither have gravitated for the same period the greater lights of the profession as practitioners, teachers, etc. These men, many of them of humble birth, self-taught, having elevated themselves to a great and noble success, do not forget their own origins, and are slow to place impediments in the way of those who have the same aspirations, the same difficult ascent to make. Hence the moderate requirements of the preliminary examination, to be followed in these schools by instruction not easily surpassed in breadth and accuracy, I am bold to say, whether it be didactic or clinical. Here hospitals are numerous and abounding in every variety of material. At Yale and the Cincinnati, Chicago, Michigan, St. Louis, and New Orleans schools the same is true, excepting the restrictions arising from moderate hospital accommodation, which will always vary with population. Here at least a third of the whole number of annual graduates receive their diplomas, and in most of these schools the final or 'pass' examination covers the entire field of study, determining the solid acquirements of the student, rather than what he may have "crammed" during the weeks previous. In some cases the 'State Medical Society' exercises a wholesome

supervision, its delegates taking active part in the oral tests applied to scholarship. Post-graduate courses are often open to the more ambitious student, and to such practitioners of long standing as may desire henceforth to restrict their work to special lines. To 'graduate into a specialty' is not with us *en règle*. It is the 'mushroom school' which gives rise to offences as rank in the nostrils of American as in those of foreign physicians. These spring up in the growing towns of the vast West, partly the offspring of local ambitions and rivalries, partly from a local demand for a not too costly medical instruction, made by the pupils and assistants of neighboring practitioners, or by youths who labor two-thirds of the year to earn the means of defraying the cost of a winter's tutelage in medicine. Few of these ever graduate, and if they do, few fail to seek their diplomas at a more legitimate fountain-head. The schools themselves meet with early graves, though their example and warning are not long heeded. It is true that all who graduate from these State-chartered schools receive the degree of M.D., and are styled 'doctors,' but in no country in the world does a man so soon find his proper level, whatever his profession or diplomas. It is the absence of social caste, the subordination of influence to real merit, the general indifference to titles, the knowledge that, after all, success must be fought for, which make the American physician so oblivious of the initialed distinctions that obtain in England and elsewhere. After all is said, in these days, when science is of common birth and acknowledges no single foster-mother, we may safely claim to be known by our fruits, and one may proudly point to the just and able criticisms of your own columns upon works of American origin for highest testimony to the value and volume of American professional attainment and culture."

The Treatment of Basedow's Disease.—Dr. W. Hale White (*British Medical Journal*) has followed up the history of twelve cases of exophthalmic goitre, and makes the following comment on the effects of treatment: Of the twelve, eleven died; but only two of these from the disease itself; the average duration was three and two-thirds years. With regard to the treatment, Jane A——, who did best of all the cases, had no treatment; Alice M—— benefited considerably from the local application of iced water; Ellen E—— was treated with the continuous current, with a good result; Ellen H—— did well on iron, digitalis, and belladonna; and Sophie S——'s account of her treatment, after leaving the hospital, is hardly trustworthy. It is noteworthy that the case which died of consumption was, as regards her Graves' disease, much improved by the application of the continuous current. Iron and digitalis are comparatively useless, and there is not sufficient evidence to show the value of belladonna; but two of the successful cases took it while under treatment by other means, so, perhaps, it had some share in their recovery. The lesson to be learned from these figures is that the prognosis of Graves' disease is bad, for the patients are partly liable to death from sudden syncope, and also seem more likely to die from other causes apparently unconnected with exophthalmic goitre; and, of those who do not die, many do not completely lose the disease. The best treatment would appear to be the continuous galvanic current and iced water. It was for this prognosis that I collected the cases; but they may be also utilized to show a few other points.

Pensioners, and the Mortality from Amputations.—A statement prepared at the Pension Office, by direction of the Chief of the Certificate Division, Mr. J. E. Smith, shows that there are only 453 pensioners of this class on the roll who have lost an arm at the shoulder-joint or a leg at the hip-joint. The small number as compared with the number of pensioners in the other classes indicate how few survive the amputation of an entire limb. There is greater danger attendant upon the entire amputation of a leg than of an arm, for there are on the rolls only 10 pensioners who have lost a leg at the hip-joint, while those who have lost an arm at the shoulder-joint number 443. They receive $45 per month. There are 3,105 pensioners who have lost an arm above the elbow, and 2,641 who have lost a leg above the knee. Such pensioners are to receive a pension of $36 per month, an increase of $6. There are also 839 pensioners who have lost an arm below the elbow, and 1,185 pensioners who have lost a leg below the knee. These pensioners are to receive $30 per month, an increase of $6. The bill further provides "that nothing contained in this act shall be construed to repeal Section 4699 of the Revised Statutes of the United States, or to change the rate of $18 per month therein mentioned to be proportionately divided for any degree of disability established for which Section 4695 makes no provision." The list of pensions now paid shows that in the higher grades the number of pensioners is comparatively small. For instance, what is termed total disability, such as the loss of both arms, both legs, both hands, both feet, the sight of both eyes, and insanity, the highest pension is paid, namely, $72 per month. The number of pensioners in these classes is as follows: Lost both arms, 21; both legs, 22; both hands, 7; both feet, 32; both eyes, 551; insanity, 190. There are only two persons who receive a higher pension than $72 per month, one of whom receives $75 per month and the other $100, the latter being General Black, Commissioner of Pensions, who received this pension by a special act of Congress. Of the 250,000 and more pensioners now on the rolls, the largest number, 60,268, receive $4 per month; the next highest number, 44,775, receive $8 per month.

The Homœopathic Treatment of Profanity.—"Another mental condition characterizing anacardium is a propensity to swear. Now, do not suppose that I recommend anacardium for the cure of profanity when it exists as a result of low morals; far from it. When, however, the propensity to swear comes as a result of mental disease, anacardium may do noble work. I once treated a minister who exhibited a remarkable *penchant* for profanity. Try as hard as he would, he could not help it. Anacardium made a complete cure in his case. Another remedy producing a disposition to swear is *nitric acid;* but I have never seen it do any good in these cases, excepting after the abuse of mercury."—*Hahnemann Monthly.*

A Dangerous Book.—The circulation of Dr. Ireland's book, "The Blot upon the Brain," has been prohibited in Russia. This is no doubt owing to the chapter on the hereditary insanity of the Romanoffs, and the historical illustrations about the harm insane monarchs have caused to their subjects.

Tracheotomy and Intubation.—Dr. F. E. Waxham, of Chicago, says that among 306 cases of tracheotomy performed in Chicago there were 58 recoveries, or 18.95 per cent.; while among 83 cases of tracheotomy there were 23 recoveries, or 27.71 per cent.

Teneriffe as a Health Resort.—It is proposed to establish near Orotava, in the island of Teneriffe, a great health resort on the plan of similar places in Switzerland, combining the advantages of a sanitarium for invalids with opportunities of healthy and instructive enjoyment for those who wish change. Humboldt pronounced the valley leading down to the sea the lovliest spot he had ever seen on earth, blessed with an eternal spring. About three miles higher up, at the old town, the air is bracing. The position lies embosomed in an amphitheatre of mountains, dominated by the famous peak.

The Virginia Medical Society holds its next annual meeting at Fredericksburg, beginning October 26th.

Remedy against Coryza.—Hydrochlorate of cocaine, grs. ij.; roasted coffee and white sugar, ʒ j. each. To be taken as snuff.

THE EVOLUTION OF THE APOTHECARY.

By W. A. PURRINGTON, D.

NEW YORK.

THE expression by Mr. Fox in an after-dinner speech, when on his special mission to St. Petersburg, of a patriotic belief that the "American language" was destined to become the universal speech, excited comment and curiosity. Matter-of-fact Britons resented this appropriation of their mother-tongue as an application of cuckoo methods to linguistics. Polyglot Russians yearned to acquire a new dialect.

Apothecary is one of those words in the use of which American differs from English and resembles Scotch; for with us, as in Scotland, prior to the passage of the pharmaceutical acts, if not now—it denotes one whose business, of a trading nature, consists strictly in selling, compounding, and dispensing drugs, chemicals, and kindred wares. The introduction into the stock-in-trade of soda-water, cigars, and confectionery, shows a tendency of the business to revert, even in great cities, to its type; for grocers and poticaries were formerly a single brotherhood, and were first incorporated into one worshipful society. Every grocer had an ἀποθήκη, by virtue of which he was a poticary.

In the fourth year of his pedantic and witch-hating reign, James I. granted a charter to "The Wardours and Fellowship of the Mystery of Grocers of the City of London," making of them a body corporate. But, as often happens where a child of his works secures a recognized social status for his family, the lesser, or junior, portion of this Mystery soon felt itself finer and more mysterious than the entire fellowship. Moreover, the blending of trades had its own inconveniences, easily conceivable to one who has been in rural districts where it still obtains. Our own Galen, who is heroic, once prescribed a very drastic remedy, and a combined haberdasher-grocer-apothecary of Westchester essayed to supply it. But the unusual dose, which "no one out here has ever took," drove him to a dispensatory, where for fifteen minutes he groped befogged, searching if a city man had anything in common with the ostrich. Only fear of not selling the drug decided him to risk decreasing the population.[1]

Perhaps (episodes of this kind as well as) a realization of the need of special care and training for the safe dispensing of medicines induced the "well-beloved Theodore de Mayerne and Henry Atkins," his "discreet and faithful physicians," to make those representations to James that induced him, in the thirteenth year of his reign, to separate the apothecaries from the grocers after nine years of union, and grant the former a separate charter under the corporate name of "The Master, Wardens, and Society of the Art and Mystery of Apothecaries of the City of London."

But although it was through the intercession of physicians that the apothecary, thus freed from the environment of grocerdom, was able to set up his own mystery, we may be very sure that the said Theodore and Henry never intended his evolution to go on until he should become, as he now is in England, a general practitioner of medicine. On the contrary, the new charter provided that the rights of the College of Physicians should not be abridged, that the college should exercise a certain supervision over the company, and that the apothecaries should consult the physicians on the use and properties of medicine.[1] The exclusive privilege granted to the apothecaries by their charter was this: "No person, free of the Grocers', or any other mystery in London, except those of the Apothecaries' Company, shall keep any apothecary's shop, or make, compound, administer, sell, send out, advertise, or offer for sale any medicines, distilled waters, compounded chemical oils, decoctions, syrups, conserves, eclegmas, electuaries, medical condiments, pills, powders, lozenges, oils, unguents, or plasters; or otherwise in any way practise the faculty of an apothecary," etc., under a penalty of £5. The only limitations upon this power were the said provision preserving the rights of the College of Physicians, whose licentiates might, under the statute, dispense medicine in their own practice, and the further provision that "approved chirurgeons" might enjoy their art "as much as belongeth and appertaineth to the composition and application of outer salves or medicines only, so that they do not vend or expose to sale to others such salves or remedies, according to the common manner of the apothecaries of London." But these provisions were not restrictions, in any proper sense, upon the monopoly of the trade. Physicians and surgeons could only dispense medicine in their own practice; they could not deal in it; and it follows that this statement of the "Encyclopædia Britannica," under the title "Apothecary": "The members of this society do not possess and *never have possessed* any exclusive power to deal in or sell drugs," is incorrect as a legal proposition.

The broad charter obtained for the physicians from Henry VIII. by Cardinal Wolsey, giving their college the licensing power theretofore vested in the clergy alone, which charter Mary confirmed, made the College of Physicians supreme in the whole field of medicine. It could license persons to examine and advise the sick, write prescriptions, dispense drugs,[2] and perform surgical operations;[3] whereas surgeons and apothecaries were narrowly limited in their respective functions. Whenever an apothecary or surgeon attempted to prescribe for the sick he stood in the peril of the law, and the college was not slow to punish him. Thus in 1602 one Jenkins, a member of the College of Surgeons, did "give judgment on urines and undertake cures." The Censors of the College of Physicians did then cause his arrest, and his counsel obtained, thereupon, a writ of Habeas Corpus; but on the return of the writ it appeared, in answer to the questions of Sir John Popham, Lord Chief Justice, that Jenkins could not justify his practice by the college seal, but could only plead: "I practised as a surgeon, and in that art the use of inward remedies is often necessary." Whereupon Sir John sent him back to durance,

[1] Romeo argued with his apothecary, hesitating to sell poison contrary to law: "The world affords no law to make thee rich; then be not poor, sell it and take this.—ACT V., Scene 1.

[1] "Proviso semper quod [illegible] compositiones et usum earundem concernent' advocabunt de tempore in tempus Præsidentem et [illegible] Majorem Civitatis London, aut alios Medicos Præsidentem præduct' nominand' pro avisamento in hac parte."—Charter, May [illegible].

[2] See the case of the Attorney-General ex rel Apoth. Co. vs. College of Physicians (1 D. & B. 231, 1 Phila. 168).

[3] 32 Hen. VIII., C. 40, 3, enlarging the original charter of the college, recites that the science of physic "doth comprehend, include, and contain the knowledge of surgery as a special member and part of the same," with which statement Dr. Davies, in his pamphlet on medical legislation, compares this saying of Celsus: "*Medicinæ autem omnes [illegible] duæ sunt, [illegible] ad curandum sequuntur.*"

saying substantially, as Goodall sums him up in his history of the college: "(1) There is no sufficient license without the college seal. (2) No surgeon, as a surgeon, may practise physick; no, not for any disease, though it be the great pox." And Sir John then further laid down six other propositions most disagreeable to Jenkins and like sinners, but of exceeding comfort to the college.

Before the incorporation of the College of Physicians the clergy were the source of license to practise physic. Successive bulls of the popes had failed to toss the priesthood out of this pleasant field of science. The college, as a corporate entity, seemed not only to have inherited the pride that marked the ecclesiastical body and caused the angels to fall, but also to have manifested it by self-mutilation, after the fashion of religious enthusiasts from the time of Atys to our own day. It was astraddle the bladder of professional pride that the apothecary floated on a silvery sea of shillings, sixpences, and half-crowns, to the humble but lucrative position of counter-prescriber and general practitioner, while the physicians, by their own acts, were impotent to stop him.

The surgeons had been originally barbers and smiths, *i.e.*, artificers; the apothecaries had been grocers, and still were tradesmen;[1] so that the physicians, notwithstanding their charter contemplated that they should dispense medicines and treat wounds and sores, enacted by-laws forbidding admission to their body to any who compounded or supplied medicine for gain, "surgeons, drug-compounders, or any other artificers of that sort, lest, perchance, if such men be admitted into the college we may seem not to have sufficiently consulted our own dignity or the honor of our country's universities, which, however, we ought, and we always desire, to attend with the deepest veneration." They decreed expulsion to any member of their college so far forgetting himself as to join the College of Surgeons or Company of Apothecaries,[2] and refused to license members of either body who did not first renounce membership therein.[3] The refusal of physicians to dispense even their own medicines; their requirement of a guinea fee for advice, and the expense and inconvenience to patients, especially in the country, of calling on the physician and apothecary, and possibly the surgeon, for a single case, were sufficient reasons why, in the course of time, the vender of drugs came to be consulted as to their use. Here was the apothecary's opportunity, especially if he had, as was commonly the case, a surgeon's license also. He was not bound to charge a specified fee, and the average man, though unwilling to pay for medical advice, is ready enough to purchase a nostrum. We love to be humbugged in gross ways. A remedy is tangible value for money; if the swallowing of it is followed by considerable discomfort the buyer is all the surer that it is efficacious. Advice, especially if consonant with common-sense, seems less valuable. If a wise physician should prescribe exercise and abstinence from rum to a victim of one of the commonest forms of "malaria," his fee would be paid grudgingly by one willing to spend cheerfully a tenth of his income in Golden Preparations and Certain Ague Cures, while keeping up, at considerable expense, the cause of his symptoms. So it came about that the apothecaries, unmindful of any gratitude they might owe to the memory of those faithful and discreet physicians who assisted their society into the world, and regardless of the limitations of their charter, fell to prescribing over their counters, and from that proceeded to visiting the sick. Let us hope that one cause of their success in gaining patients, as set out by one Doctor Murett, in 1669, in his lamentation over their encroachments on the privileges of physicians, was less important than he seems to have thought it, for he says that physicians unawares had been instructing apothecaries in their science by "sending them to visit their patients to give them the best account they could of the state of their health and effect of their medicines, and of late years taking them with them on their visits," so that during the plague of 1661, "*most of the physicians being out of town*," the apothecaries were enabled to "take upon them the whole practice of medicine."[1] This would imply that the physicians of the period were not only negligent of their duty in fair times, but that they fled their posts in time of danger, a charge savoring more of dyspepsia than of truth.

Whatever the causes were, the encroachments were made and punished during the period between the chartering of the company and the year 1703, when the House of Lords finally settled it in the case of William Rose *vs.* the College of Physicians, that an apothecary might prescribe his own remedies as well as sell them. This case is worth considering, for it was the last important step in the progress of the apothecary toward his present status as a general practitioner of medicine. The facts were these: William Rose being an apothecary, and John Seale, butcher, a sick man, the said Seale did send for the said Rose, who thereupon coming, did shake his head and look as wise as the whole Faculty, at which being much comforted, the thrifty butcher did ask the apothecary to send him something for his cure; whereupon the said Rose, not taking advice of any physician, did send some boluses to said Seale; charging therefor, but not for advice. The case does not state the effect of the boluses, nor is it important; for whether the patient was killed or cured was not material to the proposition of law, that it was alike contrary to the form of the statute for an apothecary to cure or kill. There does not seem to have been any doubt in the minds of the judges when the College of Physicians brought Rose up with a round turn for this his performance. It was argued several times—for Rose, as the result shows, was pertinacious—but the court, having true legal respect for statutes, said, unanimously, yet with a bit of sting in the tail of their judgment: "The making up and compounding medicines is the business of an apothecary, but the judging what is proper for the cure, and advising what to take for the purpose is the business of a physician; therefore, let the distemper be what it will, the prescribing and advising what is fit for it is the business of a physician, though without a fee; but that rarely happens," and it was unanimously agreed that the practice of physic in the meaning of the statute consisted:

"(1) In judging of the disease and its nature from the constitution of the patient, and many other circumstances.

"(2) In judging of the fittest and properest remedy for the disease.

"(3) In directing or ordering the application of the remedy to the disease; and that the proper business of an apothecary is to make and compound or prepare the prescriptions of the doctor pursuant to his directions; and it was agreed that the defendant's taking upon himself to send physic to a patient, as proper for his distemper, without taking aught for his pains, is plainly a taking upon himself to judge of the disease and fitness of remedy, as also of the executive or directory part."[2]

The appeal being taken to the House of Lords, it was argued for Rose:[3] "That the consequences of affirming the judgment would be to ruin all apothecaries, for in that event they could not follow their calling without the license of a physician;

"That constant usage and practice shows that selling a few lozenges or a small electuary to any person asking a remedy for a cold, or in other ordinary or common cases where the medicines had a known and certain

[illegible]

[1] Cited from Dr. Morris's Outline of Pharmacy in Ireland, in West R., April, 1858.

[2] 3 Salk., 17; 6 Mod., 44.

[3] See Parl. Rep. [illegible]

effect, where no fee was taken, could not be deemed practice of physic ;[1]

"That such affirmance would give physicians a monopoly of practice to the great harm of the public ; for it would lay a heavy tax on the nobility and gentry, who, in the slightest cases and *even for their common servants*, could not have medicine without consulting and feeing a member of the college ; it would deprive the poor of any advice ; it would be prejudicial to those suffering accident and taken sick in the night who send for an apothecary, who would risk the penalty if he applied the least remedy."

For the college it was argued that :

"By several orders of the college its members were enjoined to treat the poor gratis, and to visit them at their houses ;

"That when it was observed that these orders were defeated partially by the high price charged by the apothecaries for medicine, the college erected dispensaries in towns, where free patients could get medicine at one-third less than apothecary-prices ;

"That in emergencies, not only apothecaries, but anyone else, might relieve his neighbor, but this was no reason why apothecaries should practise at their leisure ;

"That in light indispositions the patient generally prescribed for himself, and the apothecary might lawfully put up the medicine ;

"That the most dangerous diseases begin with light symptoms, and the apothecary is not bred to detect them ; moreover, he is likely to sell his drugs plentifully, and if he makes a mistake in diagnosis, to cause great harm in what might have been remedied by proper treatment."

In spite of these arguments the Lords reversed the unanimous judgment of the Queen's Bench (how the vote stood does not appear, nor are the reasons from which the conclusion was drawn given. Whether the Lord Chancellor, sitting alone in solemn majesty, decided the question, or whether the lay Lords were affrighted at the prospect of having to employ a physician, as well as buy physic, for their common servants, we cannot know. What is certain is that the judges were reversed) ; and it was from that time on settled in England that an apothecary may prescribe as well as sell his own drugs. Two questions remained open : Whether an apothecary could recover, in an action at law, fees for medical advice,[2] or write a prescription for medicine not dispensed by him.[3]

In 1815 the Apothecaries' Act (55 Geo. III,C. 194) and in 1825 an act (6 Geo. IV., C. 133) amendatory of it, were passed, revising and confirming the ancient charter of the company. At this time the state of general medical education in Great Britain was deplorable. The case of Rose had established the right of an apothecary, with no other instruction than what he might have picked up in his apprenticeship behind the counter, to practise medicine. The powers of the College of Physicians appear to have been exercised rather too often against competent men, including graduates of the Scotch and Irish universities, and even of Oxford and Cambridge, as in Bonham's case, and too infrequently against veritable quacks and impostors. It was no simple matter to get the license of the college, and yet unlawful for the best-trained man to practise in London without it. The physicians seem to have forgotten that a charter, such as theirs, has no other *raison d'être* than the benefit to accrue to the public from the creation of a class of skilled medical men and the weeding out of the ignorant and inept. There was a little too much of the spirit of trades-unionism in their enforcement of the object of their charter as recited in its preamble.[1] The practice of medicine had fallen to a very considerable extent into the hands of quacks and incompetent apothecaries, while competent men were hampered by artificial restrictions. The company, thus freshly re-organized, set themselves about remedying this evil. The right of apothecaries to prescribe being established, the company licensing them now recognized that the right to advise implied the duty of care and wisdom in advice to which medical training and instruction were pre-requisities. They accordingly required candidates for their license to stand successfully examinations in chemistry, materia medica and therapeutics, botany, anatomy, and physiology, and the practice of medicine. The effect was that great benefit accrued from the act ; and this was frankly admitted by the physicians who at first disapproved of it.[2] Another effect of the act was to increase greatly the number of licentiates of Apothecaries' Hall as compared with the college. In the decade from 1848 to 1858, the year of the passage of the Medical Act, the licentiates of the College of Surgeons numbered 4,915, many of whom were, of course, apothecaries ; Apothecaries' Hall licensed 2,823, and the College of Physicians only 242. These statistics appear to have opened somewhat the eyes of the physicians, and shown them that the framers of their broad charter were wiser, perhaps, in their generation, than were they who drafted the by-laws. But it is a hard thing to admit errors ; so that the college did not entirely relax its old rules to meet the new crisis ; but in 1860, two years after the passage of the Medical Act, while still preserving in the by-laws the provisions prohibiting membership or fellowship in the college to anyone engaged in trade, or the practice of physic or surgery in partnership, or engaging to share profits on medicines with a chemist or other person, they nevertheless resolved to license a class of persons privileged to compound and dispense medicine in their own practice. Thereupon the apothecaries, who had come to believe themselves alone entitled to engage in general practice, filed an information and bill by the Attorney-General[3] against the college, praying that defendants should be restrained from thus amending their by-laws and granting such licenses. Mr. Roundell Palmer and others represented the college, and the case coming on in April, 1861, Wood, V.C., in an exhaustive opinion, sustained the right of the college under their charter to grant licenses in the entire field of physic.

We have thus seen the English apothecary not only evolve from a grocer into a general practitioner, but even acquire the assurance to attempt the curtailment of the chartered rights of the physicians. But it is not to be supposed that the apothecary, in our sense of the word, that is to say, the chemist and druggist, or, to use the English statutory term, the pharmaceutical chemist, is entitled to prescribe his drugs in England. The contrary has been held in two very recent prosecutions brought by the Apothecaries' Company to show that what was very good reasoning in 1703 to establish the right of Apothecary Rose to prescribe, is very poor logic when applied to Chemists Nottingham and Harrison. These two cases show very clearly the law applicable to counter-prescribing, as it has always been laid down by the law courts, on both sides of the Atlantic. They merit, therefore, full exposition.

In the Apothecaries' Company *vs.* Nottingham,[4] tried

[1] Compare Apothecaries' Co. v. Knottesham, 1 Str.

[2] A case very similar to this was tried in Massachusetts, and the court there held that the charge for the former sufficiently great to include a fee for the latter. The case may be found in 4 Cushing's Reports, p. 11 ; Morgan v. Hallock, Adams' Rep.

[3] This is still meat for lawyers. But it is certain that although under the Apothecaries' Act, an apothecary may not compound a qualified physician's prescription, he is not bound to compound one written by a fellow apothecary.

[1] "Cum regali [illegible] ... [illegible] ... [illegible] ...

in January 27, 1876, before Baron Bramwell, it appeared that the defendant, although only a chemist himself, was in partnership with a medical practitioner duly qualified, to whom he always referred such patients as in his opinion were seriously ill. It did not appear that he ever left his shop to prescribe, but it was admitted that he was in the habit of giving advice over the counter in what he considered trivial cases. In charging the jury the learned Baron said: "You have to find a true verdict on the evidence, *whether you like the act or not.*[1] Perhaps you may think that a person has a right to practise as he likes, whether qualified or not; or, on the other hand, you may think that, whereas the poorer classes have no opportunity of judging of or of ascertaining the qualifications of the persons to whom they resort for medical advice, the legislature should require such persons to possess proper skill and knowledge, and to obtain a certificate thereof. No doubt some people like to go to unqualified practitioners so as to get advice cheap; but there is the law, and we have to observe it. If you think this man has 'acted or practised as an apothecary,' then you must find your verdict for the plaintiff. Indeed, I feel some little difficulty in putting the case to you, for on the defendant's own admission he says he prescribed, and that if a person brought a child to him suffering from, say diarrhœa, and asked what was good for it, he gave the medicine; if, however, the case was serious, he sent the doctor. Surely that is acting and practising as an apothecary within the meaning of the act?"[2] Still more recently, in July, 1879, this whole subject was carefully and learnedly considered by Judge Matteran, Q. C., in the case of the Apothecaries' Company *vs.* Harrison.[3] The facts proved were that Julia Caddick went to the shop of defendant, a chemist, said she was suffering from weakness, and asked for something to relieve her. Defendant asked the cause of her weakness; she answered that it was left on her after confinement. He felt her pulse, looked at her tongue, and asked her to describe how she felt. She did so. He made up a medicine and charged only one shilling. Defendant's counsel urged in his behalf every argument brought forward for Rose, whose case, as we have seen, settled the right of the apothecaries to prescribe. He also tried to distinguish the chemist from the apothecary, by the criterion that the former could only practise in the shop, while the latter might visit; but the court said that the apothecary's right to visit was not clear as a legal proposition. Judgment was given for the company plaintiff, and the judge, citing the opinions of Bramwell and Creswell, *supra*, concluded his own opinion with these words, the applicability of which in this State and County is obvious to one familiar with their law and charities:

"I cannot, however, close this judgment without expressing my conviction that the act was intended (which intention has, I think, been successfully carried out) to have a beneficial action on the poorer classes. The more scientific masters of medicine being otherwise engaged, have no time to compound and dispense their own prescriptions; these, therefore, to save more valuable labor, are relegated to the chemists and druggists, who, if not a less highly educated class, are at least a class who have not passed the necessary examination to entitle them to practise as apothecaries. Now if the chemists were permitted to advise on the ailments of the poor, as well as to make up their drugs into medicines, the sick poor would lack the benefit of that highest class of skill which the rich by their purses can command. But this want has been provided for the necessitous at our public hospitals and dispensaries, where the ablest physicians, surgeons, and apothecaries in the land generously give their time and best skill to all comers, on whom not only sickness but poverty is pressing. The counsel for the defendant argued that the poor would suffer by limiting the action of the druggist according to the express language of the act; but to this argument the best answer is given by the act itself, which protects, benefits, and furthers the highest interests of the sick poor, by pointing and directing them to our public medical institutions for advice with reference to their ailments, and to the chemists for their medicines, when such are required, and are not provided for by those noble and charitable institutions."

Here, then, we leave for the moment our apothecary. Having triumphantly established, within less than a hundred years from his abandonment of the grocer, his own right to practise medicine, and having as triumphantly blocked, for nearly two hundred years, encroachments, exactly similar to his own, by the chemist, we have seen him, within the last twenty-five years, lay violent hands upon the venerable college whose members gave him his first start in life as a tradesman of a distinct sort; and we have seen him beaten in this assault, planned in the interest of his corporation as a trades-union, and not as the dutiful public servant that every corporation should be.

The apothecary's history is profitable for instruction. Not its least obvious lesson is that so long as the laws affecting the practice of medicine and the incorporation of medical societies are exercised, in pursuance of their ostensible object—*i.e.*, the furthering of the public welfare by requiring of practitioners conformity to a reasonable standard of professional attainment, those laws can be enforced; but that, whenever such legislation is attempted to be exercised in a selfish spirit of trades-unionism, for the benefit of corporations and their members, and in disregard of the public needs and convenience, the same laws will be nullified by close technical constructions, and if not repealed will fall into "innocuous desuetude." The medical profession in this country has been free, fortunately, from those arbitrary limitations which enabled the untrained apothecary partially to supplant the physician in England, by making it unprofessional for the latter to engage in the practice of medicine to the full extent authorized by the charter of the college granting his license. And there seems to be no adequate reason why the apothecary with us should be suffered to prescribe chalk-mixtures for "light cases of diarrhœa," bromides for "nervousness," and so forth. A judge in this city said some time ago that the court would take judicial notice of the fact that a lawyer could be found in half an hour for any client. And what with hospitals, infirmaries, dispensaries, night medical service, and about twice as many well-equipped physicians as lawyers in the county, there is certainly no crying need for laymen to render medical assistance except in cases of emergency.

[1] Our italics. There are similar New York cases affecting persons practising medicine under the guise of selling drugs.

[2] See Mr. Lumley's report of the matter, but see also [illegible] and apothecaries, in Apothecaries' Co. v. Lottinga, 2 M. and R., [illegible]

Parenchymatous Injections of Quinine in Ague Cake.—Professor F. Fazio relates in the *Rivista Clinica e Terapeutica* for July, 1886, the case of a woman, thirty years of age, who had suffered from malarial fever, and who had also marked hypertrophy of the spleen. The tumor extended from behind the margin of the ribs to a line drawn on a level with the anterior superior spine of the ilium. It was determined to attempt a reduction in the size of the spleen by means of parenchymatous injections of quinine. The instrument used was the ordinary hypodermic syringe provided with a longer and thicker needle than usual. The bisulphate of quinine was employed, and thirty-two injections of each 4½ grains were made, care being taken to make the successive punctures at some distance from each other. The result of treatment was a reduction of over one inch in the length of the tumor. The injections were not followed by pain or by any other unpleasant symptoms. The experiment was interrupted by the departure of the patient from the hospital, but Dr. Fazio believed that the results obtained were sufficiently encouraging to warrant further trials of the method.

A STUDY OF HERPES ZOSTER FRONTALIS SEU OPHTHALMICUS, WITH A CASE.

BY ALFRED HINDE, M.D.,

SURGEON TO THE EAR AND EAR DEPARTMENT, CENTRAL DISPENSARY, ETC.

T. T——, aged thirty, English, has been in the United States two years, and is a grocery clerk by occupation. He suffered from a very slight attack of small-pox twelve years since, and was then sick two weeks; had only two or three pustules over the entire body; one of these was on the abdomen, another on the right parietal region, but none on the forehead or face; his health was not afterward impaired. Two years later he had what his physician called "congestion of the brain"—had then much headache, but no delirium—and was sick three months, seven weeks of which time he spent in bed. He attributes the attack to overwork. Since this sickness he has had pain in the right knee-joint, but the latter has never been swollen. He has been troubled more or less with dyspepsia; otherwise the patient has been healthy.

There is no history of nervous disease in his family. His mother died of consumption at fifty, and a brother died of the same disease at twenty-five years of age. Family history otherwise good.

Patient first seen by me at the eye clinic of the Central Dispensary, January 22, 1885, when he gave the following history of his present sickness.

During the first week of August, 1884, he was exposed to a draught in the store where he works, and thinks he "caught cold." The following day he noticed a "twitching" of the upper eyelids of both eyes, which lasted for two days. A severe pain over both eyebrows then commenced, and extended upward and backward over the frontal and involving the tissues covering the anterior portion of the parietal regions. The pain was most severe on the right of the median line, and had lasted for forty-eight hours, when he applied ice-cold cloths to the painful parts during one night. Next morning his right upper eyelid was swollen and heavy, and overhung the ball so that he could not see unless he lifted up the lid with his finger-tips. The eyeball was pale, and his eyesight not as yet affected.

The pain over the frontal regions still continued, and he describes its character as lightning-like and intermittent in severity, but at no time was he entirely free from it, and the right side still continued to be the most affected. Besides the painful regions already named, the pain extended half-way down the right side of the nose, but was absent around the tip and within the nasal cavity.

About the time the right upper eyelid swelled he observed a crop of "water-blisters" over the painful region to the right of the median line. After their appearance the pain abated somewhat, but did not disappear. The vesicles appeared so quickly that, to use the patient's own words, "They were there before I knew it." He says there was no swollen, reddened base preceding the vesicular eruption. The fluid in the vesicles was clear. Vesicles were present over the right frontal region, involving the first inch of the hairy scalp; laterally they did not extend below the level of a line drawn from the outer canthus. The greater number were grouped for two inches above the base of the nose and near the median line, some crossing the latter for three-eighths of an inch. Above the right zygoma were two or three. On the upper eyebrow was one linear vesicle nearly one inch in length, extending downward and outward. The skin of the upper eyelid was the seat of two vesicles. Vesicles appeared over the right side of the nose, especially at the base around the internal canthus, and at and around the tip; the outer middle portion of the side of the nose was little involved. There were no vesicles on the lower eyelid, nor on the cheek.

He applied a solution of sugar of lead to the vesicular regions, and crusts formed, remaining several weeks.

The right eyeball became red and inflamed about the tenth day after the first appearance of the symptoms. He had, however, suffered from pain—similar in character to that already described—in the globe of the eye for four days before it became red, and the sight diminished at the onset of the pain. He also suffered from marked photophobia and profuse lachrymation, together with a thick discharge which glued the margins of the lids together, so that each morning he had to moisten the crusts before he could separate the eyelids.

The vision of this eye was now so markedly reduced that he could not see to read any type at any distance, neither could he distinguish one friend from another in the same room. The near and distant vision were alike. He describes his vision as clouded.

Thus the vision of this eye continued for four months, when he noticed it began—more or less suddenly—to clear up a little, but not sufficiently to read any but the very largest advertising type, though he could now discern one friend from another.

The pain, which had continued with almost unabated severity these four months, began to lessen at the same time that the sight began to improve. Now complete intermissions appeared, and these same periods of freedom from suffering have become more and more prolonged, and the painful area more and more circumscribed, until, at the present writing (January, 1885), he has from one to four paroxysms of pain in the twenty-four hours, each of which lasts from fifteen to twenty minutes.

The painful region is of circular form, of about an inch and a half in diameter, with the right frontal eminence as its centre. There is an occasional twinge of pain in the upper ciliary region of the right eyeball.

The pain is still of a stabbing character—comes suddenly, and is gone "before I know it." He considers that it is still steadily abating, though his sight is stationary. He has never been feverish, nor has he felt sick at any time during the attack; he had never before suffered from neuralgia nor other pain, except in the right knee-joint, and this was of a steady, aching character.

Condition January 22d.—Scattered over the right half of the frontal region are pale, punched-out, depressed cicatrices, more or less circular in form, and about the size of half of a No. 4 shot. They are most numerous and deepest near the median line, which they cross for three-eighths of an inch, and they appear grouped irregularly from the base of the nose to a mid-point between the latter and the margin of the hairy scalp. About one inch above the right zygoma may be seen a couple of discrete spots. Situated over the middle of the right eyebrow, among the hair, is a depressed linear scar three-quarters of an inch in length, passing downward and outward. There are two discrete, shallow spots on the right upper eyelid—the latter are the least marked of all the scars.

The skin of the right half of the nose, with the exception of a small portion at the outer mid-region of its side, and limited accurately by the median line, and especially around the inner canthus and over the nasal cartilages and tip, is the seat of grouped and discrete cicatrices similar to the foregoing. The skin of the affected regions is very markedly anæsthetic, as ascertained by the æsthesiometer, though the patient did not appear to be previously cognizant of the fact; that of the lower eyelid and cheek, and also that of the left side appear to be normal.

The right upper eyelid droops somewhat below that of the left eyelid, causing the right palpebral fissure to be the smaller of the two. The right lids appear in other respects normal. The lateral portions of the sclerotic are alone exposed and appear red, due to large, tortuous vessels wending their way from the canthi to the margin of the cornea. Near the latter are seen many more smaller tortuous vessels which fringe the lateral corneal margins. On separating the lids, so as to see the

junction of the sclerotic with the cornea above and below, other large, tortuous vessels are seen crossing over the sclerotic toward the limbus corneæ, where they disappear; the latter above and below is pale and free from the smaller tortuous vessels seen at the lateral limbus. No straight vessels are seen around the ciliary region.

The anterior portion of the sclerotic is more transparent than in health, and shades from a normal opaque-white near the equatorial region to a more or less mottled bluish-brown color near the margin of the cornea—such as seen in commencing annular ciliary staphyloma. This thinning of the sclerotic is most marked below the horizontal meridian of the eyeball.

On the corneal surface, and occupying only the pupillary area of the same, is a punctate abrasion of its epithelium, and, by oblique illumination, the finest superficial milkiness is perceptible, having fine, thread-like processes crossing its surface, but no ulceration.

The right ocular conjunctiva and the cornea are[1] anæsthetic, so much so that he permits my finger-tip to rest upon them without flinching—he says he feels it, but experiences no pain. The same parts of the left eyeball object even to the attempt at touch.

The anterior chamber is shallower than normal, the iris arching forward somewhat and the lens apparently advanced. The iris, of blue color and slightly muddy appearance, has large trabeculæ and looks swollen. The pupil is medium-sized and not strictly circular, the upper and outer portion of the iris being narrower than the remainder. To direct oblique illumination the iris is immovable, but consentaneously the faintest perceptible contraction is seen at the narrower portion. The fundus cannot be distinctly seen on account of the milky cornea, but the media appear fairly clear, for the disk is readily discernible from the remainder of the fundus. The tension of the ball is, if anything, slightly above normal.

The lids of the left eye are normal, sclerotic and cornea healthy, the anterior chamber shallower than normal; the iris, of clear blue color, arching forward slightly and evenly toward the pupil, is very sensitive to light, contracting readily both directly and consentaneously. The pupil is circular and of medium size. The media are clear; disk not transparent yet not perceptibly swollen; its details covered somewhat; its margins not clean cut but veiled, and extending from the latter a finely striated cloudiness is visible. Entire fundus has a misty appearance, so that its finer details are befogged. The retinal arteries, both on and off the disk, are very tortuous, pale, and, if anything, of decreased size. In places the outline of the vessels cannot be distinctly focussed, as if partially obscured in the swollen fibrous layer of the retina, but at no point do they disappear altogether. The retinal veins are straight, possibly a little larger and darker than normal.

Tension plus one. By direct examination I decided patient was emmetropic.

Acuity of vision.—Each eye tested separately. Right eye V= $\frac{6}{1 \text{XXX}}$, and rejects both plus and minus glasses; made only No. 10 Snellen at 6″ without glasses, and not any glass improves vision. Left eye V= $\frac{20}{\text{XXX}}$, and rejects both plus and minus glasses; sees Snellen's half circle equally distinct; reads No. 1 Snellen at 6″ to 13½″ without glasses, thus showing normal accommodation.

He considers that his vision with this eye is not as acute as before the disease commenced.

In the early period of the disease he had used a solution of atropine night and morning for one week. Knowing this, and being desirous to ascertain if there was a posterior synechia of the right eye, I inserted a very small portion of an ointment of atropia and morphia between the lids. After waiting forty-five minutes—being busy during this time—the pupil was seen to be egg-shaped, with the small end upward and outward, corresponding to the movable and narrowed portion of the iris. Three-fourths of the iris remained fixed, and the remaining fourth contracting caused an apparent displacement of the pupil up and out. The fixed iris looked more swollen, and its enlarged vessels were visible, giving it a brownish color. He said his eye ached during the first fifteen minutes after the application, and on questioning him now on the effects of its previous use he said the eyeball ached after each instillation, and during the latter two of the seven days the suffering became so great, and the cloudiness so marked, that the surgeon in charge stopped the further use of the atropine. The tension now seemed to be slightly reduced, but on palpation over the upper and outer ciliary region, contiguous to the contracted iris, he complained of pain; on previous palpation such was not mentioned.

The disk could be seen slightly more plainly, but not sufficiently so to satisfactorily describe.

Remarks.—From the distribution of the cutaneous scars it will be seen that the affected regions receive their sensory nervous supply from the frontal, lachrymal, and nasal branches of the ophthalmic division of the fifth cranial nerve. The couple of pits above the right zygoma are in the region supplied by the temporal branch of the upper maxillary nerve. This temporal branch, however, in its course through the orbit, receives a filament from the lachrymal nerve, and we may justly attribute the temporal scars to these added fibres. The lower lid receives its entire sensory supply from the palpebral branch of the superior maxillary nerve, and was not involved.

The ocular inflammation was transmitted through the ciliary nerves and lenticular or ophthalmic ganglion—which latter receives its long, or sensory, root from the nasal branch of the ophthalmic nerve—or directly from the nasal branch through the long ciliary nerves. The ciliary nerves—short and long—supply the eyeball. Thus we can trace the disease to the branches of the ophthalmic nerve; but is this the *fons et origo*, and what is the pathological process involved?

The patient was observed without any local treatment until February 5th, when eserine (gr. iij. to ℥ j.) was instilled into the right eye. From the 5th to the 15th, owing to the extremely severe weather, the distance, and an acute catarrh, the patient's attendance has been very irregular. During this period of ten days eserine has been used six times. The right pupil before the instillation had a diameter of four millimetres, and thirty minutes afterward a diameter of two and a half millimetres. The contracted pupil occupied a position within the lower inner quadrant of the cornea, in the angle formed by the horizontal and vertical meridia of the same. He has never experienced the slightest intraocular uneasiness at the time of, or between, the applications. Soon after the first use of eserine the previously continuous cloudy vision commenced to clear up somewhat, but only momentarily, relapsing again into thick cloudiness; later the cloudiness appeared less marked, and the clear interval more clear and prolonged; still later the clear intervals appeared twice daily, and lasted longer each time; now (15th) they recur three or four times daily, and he notices that his vision is always clearest in the early morning, and the cloud is steadily decreasing in density, and he can, for the first time since the onset of his eye-disease, read the clock in his room at eight feet distance. From January 22d to February 5th the right eyesight was stationary ($\frac{6}{1 \text{XXX}}$), but during the last ten days with this eye the vision has risen to $\frac{12}{1 \text{XXX}}$—just double the amount.

The second testing occurred on January 28th. At this time the left eye had a vision of $\frac{20}{\text{XXX}}$, and the right eye same as at first. Internal treatment commenced at this date, and consisted of cod-liver oil, quinine, and iodide

[1] [illegible] what he observed. He stated that in the right eye he had neither pain nor lachrymation [illegible] have since tested the same on two occasions, and with the same results, viz.: in the right eye no pain and no tears, whereas in the left pain was experienced and the tears flowed down the cheek. This experiment was tried on account of a similar observation noticed by one of Anstie's patients and referred to elsewhere.

of potassium, each given separately. On February 8, eleven days after the commencement, the vision of the left eye had risen to $\frac{20}{XX}$—normal.

March 3d.—During the last seventeen days eserine has been instilled into the right eye twelve times, and there has been a steady improvement in the acuity of vision, without the least intraocular irritation in this period of time. The vision has not been, neither is it yet, a constant quantity, varying from slight cloudiness (on exposure to bright light or due to fatigue) to very distinct vision (especially on first rising in the morning before exposure to light, and again in the evening).

In the store where he works he is exposed to the glare of the electric light, and he probably thinks correctly that this is the cause of his fluctuating vision.

During the last three or four visits I have noticed a steadily increasing injection of the ocular and palpebral conjunctiva of the right eye, until at the present there is an acute conjunctivitis. I consider the latter due to the eserine instillations and have stopped the same. There is, however, no intraocular irritation. Acuity of vision of the right eye, tested March 1st, and found as follows, the light being only fair: V = > $\frac{20}{XX}$; deciphers half the types correctly; reads No. 1 Snellen at 8″ with some difficulty, and No. 1 Jaeger readily at 6½″ to 10″, easily by choice at 7″.

He says he has been able to read ordinary newspaper print since February 20th with this eye. The cornea and media are now transparent, and the fundus can be readily seen, and to avoid needless repetition, I may state that in all its present characters it is similar to the left fundus already fully described.

The cornea, conjunctiva, and skin are still as anæsthetic as when first seen. He has been entirely free from all neuralgia for the past two weeks.

Since writing the foregoing history, which may be considered a typical one of the disease, with the exception that usually the vesiculation and scarring is limited by the median line, through the kind permission of Dr. E. L. Holmes, I have had the opportunity of consulting the fifth and sixth volumes of the "Royal London Ophthalmic Hospital Reports."

In these I find recorded 51 cases of herpes frontalis. Jonathan Hutchinson has collected 41, of which 26 were his own, occurring during a period of eight years. Mr. Bowman reports 9 cases, all his own, observed between the years 1855 and 1866. Dr. F. M. Mackenzie records one case in the *India Medical Gazette* of August 2, 1861. Together with the accompanying case these make 52 cases, and the subject of our present study.[1]

Unfortunately the records of the 52 cases are in many respects so imperfect that they greatly limit the usefulness of our study. Especially is this so in regard to the complications. The notes referring to the ocular inflammations are unfortunately so limited as to actually leave us in the dark as to the character of the same and its exact effects—the tension of the ball scarcely referred to, the acuity of vision rarely mentioned, and ophthalmoscopic description in one case only besides my own given.

Of the 52 cases, 31 occurred in males and 21 in females. The youngest patient was three and a half years of age, the oldest seventy, and of the later age there were two examples. The average age of fifty of the cases—in two it was not given—was 37.31 years. Before the tenth year there were 4 cases; between the tenth and twentieth years, 6 cases; between the twentieth and thirtieth years, 9 cases; between the thirtieth and fortieth years, 3 cases; between the fortieth and fiftieth years, 8 cases; between the fiftieth and sixtieth years, and the sixtieth and seventieth years, in each 10 cases.

The period of greatest immunity from the disease was during the fourth decennary, the largest number occurring equally during the sixth and seventh periods of ten years. Up to and including the fortieth year there were 22 cases; from the fortieth to the seventieth year there were 30 cases. The above would seem to show that the latter half of life is the period of greatest frequency of the disease. Where the previous health of the patients is referred to, in 20 cases it was good, in 5 it was feeble.

In 25 cases the right side was implicated, and in 22 the left was alone involved; in 5 cases the notes are imperfect.

From the distribution of the vesicles or the remaining scars, the first division of the trifacial was alone the diseased nerve in 48 instances. In the remaining 4 cases the superior maxillary nerve was implicated with the ophthalmic.

Motor disturbances were present together with herpes in 4 cases. The third nerve was affected in 3 of these, being completely paralyzed in 1, divergent strabismus existing—this case, however, made a complete and rapid recovery; in another there was partial ptosis, whether permanent or not is not stated; in the third case, ptosis, with markedly dilated and fixed pupil, was present, but no recti muscles were paralyzed or impaired; in the fourth case permanent internal strabismus was present, thus showing a paralysis of the sixth nerve and external rectus muscle. Hutchinson also states (vol. v., p. 258): "In all the cases which I have seen, in which the eye was affected, paralysis of the iris and total immobility of the pupil ensued."

Following Hutchinson's method we find that in its entirety the ophthalmic nerve was affected only in 2 cases; its frontal branch alone in 20 cases; the frontal and trochlear in 15; the frontal, trochlear, and oculo-nasal in 13; the superior maxillary in part, and all the ophthalmic in 1 case; the superior maxillary in part, and the frontal branch of the ophthalmic in 2 cases; the superior maxillary in part, and the frontal and oculo-nasal branches of the ophthalmic in 1 case.

In the differentiation of the affected nerve branches Hutchinson considers it difficult to state whether the lachrymal nerve is involved or not, yet he thinks where there is much upper-lid eruption, with "great swelling and much conjunctival congestion, we may safely believe that the lachrymal nerve is concerned."

It would seem more difficult to separate the lachrymal nerve from its share in cases of zoster frontalis than it would be to state in which cases it was involved. True, its fibres run side by side with, though separated from, those of the most frequently affected of all the branches of the ophthalmic, viz., the frontal, and we might infer that the origin of the two sets was the same; yet if this were so, they need not necessarily be both implicated, for, as will be seen later, it seems possible to have limited peripheral examples of this disease.

Seeing, however, that the lachrymal gland and upper lid receive their main nervous supply from the lachrymal branch, and seeing also that through the latter's connection with the temporal branch of the superior maxillary nerve it aids in the supply of the temporal region; again, seeing that upper-lid vesiculation and swelling, together with profuse lachrymation, and also temporal scarring, are present in the large majority of cases of herpes frontalis, we think we are justified in considering that it is the rule for the lachrymal branch to be involved in this disease.

Therefore a more simple division of the cases would be as follows:

Frontal and lachrymal nerves affected in 35 of the 52 cases; frontal, lachrymal, and oculo-nasal in 13; first and second divisions of the fifth, more or less combined, as before referred to, 4 cases.

The eyeball of the affected side became inflamed in 19 cases; in 6 of the others the eye is not mentioned; in 2 other cases there was conjunctivitis only. In the case where the third nerve was completely paralyzed the nose escaped and the eye was not inflamed. In the case of internal strabismus with diplopia the nose escaped and the eye did not inflame.

[1] One case may [illegible] have been [illegible] Hutchinson's further [illegible]

In the 19 cases in which the eye inflammation accompanied the zoster there was an associated nose implication in 15 of them; 13 of these occurred in Mr. Hutchinson's series, one only occurring in Mr. Bowman's cases (the remaining one is my own patient). Mr. Bowman records 4 cases of eye inflammation without any affection of the nose, though the forehead and infra-orbital regions were both involved in one of these. Vesicles or scars were present in 5 cases—all Mr. Hutchinson's—yet the eye was not inflamed. Here it may be remarked, however, that there were only one or two in each case above the mid-region of its side, and usually not below the level of the inner canthus. In one of these five cases ptosis was present, showing paralysis of the levator branch of the third nerve.

Thus Mr. Bowman had nose implication in 2 out of 9 cases, together with 4 cases of eye inflammation without nose involvement, whereas Mr. Hutchinson had 18 cases in which the nose was affected out of a total of 41, but not a single case of eye inflammation without an associated nose disease. We need not wonder, then, from their widely different experiences, that they should differently construe the same. On this subject Mr. Hutchinson says that he has never seen the whole side of the nose affected without also witnessing inflammation of the eye, and has never seen the eye inflame unless the side of the nose showed vesicles.

Bowman says he has not found affections of the eyeball to occur specially in those cases of ophthalmic zoster in which the eruption followed the course of the nasal branch.

Mr. Hutchinson says later that his rule ought perhaps to be modified a little, but that "it would be quite safe to assert that the eye scarcely ever suffers much when the nose is not affected, and that the severity of the eruption on the one part is usually in direct relation with the severity of the inflammation of the other."

Thus we have different views expressed by the early recorders of this disease. Though both are partially right yet neither expresses the entire truth. We will try to explain the nose-scarring without the eye inflammation, and the eye inflammation without nose disease. With one exception, in the cases of nose implication occurring without subsequent eye disease the scarring was limited to the upper half of the nose, was usually seated above the level of the inner canthus, and was in amount slight. Here the region of the trochlear nerves is alone involved. The supra-trochlear branch of the frontal leaves the orbit above the pulley of the superior oblique muscle "to end in the eyelid and forehead. Before the nerve turns round the margin of the frontal bone it sends downward a branch of communication to the infra-trochlear branch of the nasal nerve" (Ellis, p. 47). Again, the infra-trochlear branch, before it "leaves the orbit receives an offset of communication from the supra-trochlear nerve," and "it ends in the upper eyelid, conjunctiva, and side of the nose."

Now, on account of this communication with the frontal nerve, and seeing that the latter is the most frequently affected branch in cases of herpes frontalis, are we not justified in considering that these few upper-nose vesicles were due to these added fibres, and that the nasal nerve was not implicated at all? Thus the five cases of Hutchinson with nose-scarring and no eye inflammation may be explained and his amended rule still hold good.

But what of the case where the vesicles were present all over the side of the nose "to its tip?"

The terminal fibres of the nasal nerve are distributed over the cartilagino-cutaneous surface around the wing and tip of the nose, yet these fibres may not be the only sensory nerve-supply to the side of the nose below the inner canthus, for Ellis (p. 115, seventh edition), in speaking of the infra-orbital branches of the superior maxillary nerve, writes, "some incline inward to the side of the nose," and again, "the branches for the side of the nose supply the muscular and tegumentary structures."

Moreover, in Case 8 (vol. vi., p. 9) of Mr. Bowman's series, "there were marks of the herpetic eruption over the right forehead, and a small patch over the infra-orbital foramen, but none on the side of the nose." This would seem to show that only a few of the fibres of the infra-orbital branches were involved. Again, we must refer to another apparent anomalous distribution of the vesicles, as shown in Case 2 of Mr. Hutchinson (vol. v., p. 197), where "the mid-region of the left side of the nose was covered with vesicles extending exactly to the median line and no farther. Neither the lower part (ala) nor the upper part of the side of the nose was affected," and in this case "the eye itself was nowise affected."

In this case the nasal branches of the superior maxillary nerve would seem to be involved.

It would seem from these cases that the nose eruption is not necessarily dependent on the nasal branch of the ophthalmic. And if it be, the apparently limited peripheral cases of the second division of the trigeminus just related would premise a possibility of only a few filaments of any nerve becoming affected, the remainder of the trunk being sound. If the latter argument be accepted, we may not only explain Mr. Hutchinson's puzzling case of entire nose implication and no eye disease by believing that the fibres of the long sensory root of the lenticular ganglion and those of the long ciliary nerves were healthy; and again explain by it the four cases of Mr. Bowman, of eye disease without associated nose disease, by considering that the ocular fibres of the nasal nerve were involved, whereas the terminal filaments of the same nerve remained healthy. This, however, overthrows Mr. Hutchinson's amended rule, and would seem to show that from the cutaneous complication no rule can be formulated whereby we can foreshadow the probability of eye disease in any of these cases.

This we believe to be the truth.

Again, if this be true, we might still further speculate, and think it probable that in such cases as the above we had instances of only peripheral disease, possibly due to external causes.

When does the eye become inflamed?

Before answering this question we must refer to a wax model in Guy's Hospital, the notes appended to which say that the boy "was attacked with inflammation of the eye, and at the same time the herpetic eruption appeared."

If these notes are accurate, the possibility of the coincident appearance of the cutaneous and eye complications of zoster frontalis is proven. In point of time they both appear subsequently to the neuralgia, and in our 55 cases the eye complication follows, usually by a distinct period, the skin disease.

In 11 of the 19 eye inflammations the notes are imperfect and no statement given. The eye became inflamed two days after the appearance of the skin eruption in Case 5 of Mr. Bowman's series, and this is the shortest period stated. The case with the longest interval was one in which the eye was first affected one month after the vesicles appeared. Both Mr. Hutchinson and Mr. Bowman think the eye affection does not appear until after the eruptive stage has reached its height, or has begun to decline.

What tissues are involved in the ocular inflammation?

In the 19 cases the cornea alone was affected in 5; the cornea and iris together in 4; the iris alone in 2; the conjunctiva, cornea, and iris in 3; the conjunctiva, cornea, and lens in 1 case. In the 4 remaining cases the eye was practically lost. In one of these atrophy of the optic disk was diagnosed; in another, "most of the tissues of the globe, cornea, conjunctiva, sclerotic, and iris" were involved, and in the case accompanying this paper, besides the cornea, iris, and sclerotic, most probably the remainder of the uveal tract and retina were inflamed. If we bulk the cases, it will be seen that the cornea was affected in 14 of them, and the iris in 10;

thus the cornea is the part most prone to inflammation, and the iris only a little less so.

The acuity of vision and eye-tension is not referred to in 10 of the 19 cases. In one case the "globe is slightly prominent;" in another, "had no useful vision;" in a third, "cannot make out large ordinary print at all;" in another, "the sight was much impaired." In only one case of Hutchinson's is the exact acuity of vision stated, viz., $\frac{6}{xxx}$, and the tension is not referred to. In my case the tension was plus normal, the acuity of vision $\frac{6}{xxx}$, and could read only No. 10 Snellen at 6'.

In reporting cases the ophthalmoscope ought to be used where possible, palpation applied, and the acuity of vision given.

The etiology and pathology of this disease cannot well be separated. On this subject Bowman thinks that zoster is a peripheral disease, having its primary seat in branches of the nerves of common sensation.

Hutchinson is rather undecided in his views, at one time considering the disease to be of central origin, at another that possibly some cases are of peripheric origin only. It would seem that he was right, and that occasionally we may have cases of essentially peripheric origin and extent. The importance of this matter, in its influence upon the treatment of this disease, cannot be overestimated, for if herpes be always due to central disease, local surgical interference would be always contra-indicated; whereas, if we could know that we had a strictly peripheral case, exsection of the affected nerves would offer the most rapid and complete relief from the neuralgia which is the bane of this disease.

Bowman has mentioned cold as a possible external cause of this disease, and my own patient was conscious of being exposed to a draught, and "caught cold," the day before the disease commenced.

The lamented Anstie, in his work on Neuralgia (1871, p. 161), says: "The effect of a continuous cold *draught* of air impinging on the naked skin for some time is comparatively frequently seen in the provocation of a neuralgic attack; we say comparatively, because this influence is more frequently effective than blows, wounds, or temporary irritations of any kind applied to the peripheral ends of sensory nerves. But if neuralgia be a more frequent consequence of cold than of these other influences, a moment's reflection will show that it is by no means an absolutely common result."

Our pathology and etiology thus are far too general and indefinite to leave at the present stage, and in Anstie's conclusions, gained from his own experience and founded on that of others, we will, with the least time and space, find all that is requisite or known to further elucidate this part of our study. He writes: "Hereditary neurosis is an important antecedent of neuralgia in at least a very large number of patients. Neuralgia has no 'pathology,' if by that word we intend to signify the knowledge of definite anatomical changes always associated with the disease. It also possesses no demonstrable 'causes,' in the old metaphysical sense." He considers "that the essential seat of every true neuralgia is the posterior root of the spinal nerve, in which the pain is felt, and that the essential condition of the tissue of that nerve-root is atrophy, which is usually non-inflammatory in origin;" and at p. 190 he writes: "The trigeminus is in all its characters a spinal nerve, but it has sundry peculiarities both of structure and connections with other nerves."

From this it will be seen that he regards neuralgias as almost, if not wholly, of central origin.

Among the reflex influences that take part in the etiology and complications of neuralgia we shall only refer to those which more nearly apply to our special study: 1. "Neuralgia in a sensory nerve may (and almost always does to some extent) produce secondary vaso-motor paralyses. These paralyses may affect fibres which run in the same branch of the nerve as that which is painful, or fibres that run in another branch of the same nerve, or fibres that run with another sensory nerve, or the ganglionic chain of the sympathetic itself.

"In the present state of our information I am inclined to explain all the congestive complications of trigeminal neuralgia on the basis of vaso-motor paralysis. And I further believe that the cause of that paralysis is a direct extension of the original morbid process from the sensory root to the motor, affecting the origin of fibres in the latter which are destined to govern the calibre of ocular and facial vessels."

He is willing to admit that increased secretion may possibly be explained by vaso-motor paralysis, but the mere cessation of vaso-motion will not account for such facts as the rapid and simultaneous development of erysipelatous inflammation, of corneal clouding and ulceration of iritis and glaucoma, or nutrition changes in hair or mucous membrane, and considers "that there is a special set of efferent fibres in the trigeminus, emanating from the motor root, whose function it is in some unknown way to preside over the equilibrium of molecular forces in the tissues of which the nerve is distributed—trophic nerves, in fact, though not active dilators of blood-vessels."

2. "Neuralgia in a sensory nerve may increase, alter, or (more rarely) suspend the secretions of glands supplied by fibres bound up in the same branch, or in another branch of the same nerve, or in a different nerve with which it is connected, only through the centre, or (possibly) only through a plexus.

"In the great majority of cases the affection is in the direction of increase, at least the watery elements of secretion are often poured out in profusion. Thus profuse lachrymation is exceedingly common in ophthalmic neuralgia.

3. "Neuralgia in a sensory nerve can produce paralysis of muscles supplied by motor fibres bound up with the painful branch or with another branch of the same nerve, or in muscles supplied by a totally distinct nerve connected only through the centre."

In this, Hutchinson's idea, that cases of zoster frontalis with motor complications are instances of central origin of the disease, is indorsed. The above statement would scarcely apply to paralysis of accommodation usually present in the cases of eye complication of zoster, and due most probably largely to compression of the nerves supplied.

Anstie regards paralysis of muscles, secondary to neuralgic affections, as "pretty common," and further writes: "I find that in twenty-eight of the hundred cases which have been referred to, no less than twelve were connected with neuralgia of the trigeminus, and in most of these it was one or more of the muscles connected with the eye that were affected.

4. "As regards vision, besides minor perversions, I have observed more or less complete amaurosis in several instances of ophthalmic neuralgia: in one case it was absolute, and lasted, with but slight improvement in the intervals between the paroxysms, for nearly a month, but disappeared entirely, though somewhat gradually, after the final cessation of the neuralgia."

When considering diagnosis Hutchinson writes: "It is often considered to be erysipelas."

Undoubtedly Anstie has made the common mistake, for he continues: "In the first case I saw (a woman of thirty-two) nothing could be more startling than the rapidity with which an irregular patch of skin, including half of one cheek, the side of the nose, and a large part of the forehead and scalp on the same side, became converted into the dense, fiery-red, brawny tissue, with minute vesicles scattered over its surface, which looks so characteristic of erysipelas. This commenced immediately on the subsidence of severe neuralgic pain."

This is a typical case of facial zoster, implicating the first and second divisions of the trigeminus.

Anstie reports two cases which are of extreme interest because different from any of those reported by Hutchin-

son or Bowman, one of them being the only instance we have found where the third division of the fifth nerve was involved in the disease.

That they were cases, not of erysipelas, but of trigeminal neuralgia, with its skin and eye complications, I have no doubt. The only likeness to erysipelas that I can find in the one in which the third division of the fifth nerve was involved was the "continuous deep-red color," which Anstie notes, of the soft tissues of the affected nerve districts; but this redness is not by any means peculiar to the erysipelatous inflammation; and the only item that was lacking in the case to make it a typical one of zoster frontalis was the absence of vesicles. Here we are confronted with the question: Is it an accident, or is it essential to have vesicles present in cases of herpes zoster? It would seem that we may or may not have vesicles present in cases of zoster frontalis, according to the character or grade of the secondary inflammation accompanying these cases of trigeminal neuralgia.

The other case reported by Anstie is a very remarkable one, as it seems to prove that there may be repeated attacks of zoster. The family history of the patient was peculiar. All the members of the family of the patient's mother, for two generations, had died at middle age of apoplexy or some disease involving hemiplegia.

Now we have been taught that zoster only occurs once in a lifetime, and with all the credence and respect that is due seniority we have not doubted the statement until the perusal of this second case. We must not forget, however, that in the past a second attack of syphilis, measles, scarlet fever, and small-pox was considered impossible. Yet it is now known that there are certain individuals who are especially prone to contract a second or more attacks of the exanthemata. The supposed rule is little less valuable in practice on account of these few exceptions, yet to-day it is not arbitrarily taught.

If the disease that we are now considering be essentially a neuralgia with added parts—and still further evidence could be adduced that would show the same to be the case—and knowing that the repetition or continuation of the causation of the same will in ordinary neuralgia invoke other attacks, why is it invariably impossible to have a recurrence of this form of the disease?

Clinical experience has proven that it must be extremely rare, or the supposed rule of protection from subsequent attacks would never have been formulated.

In this second case of Anstie's the remarkable neurotic history is little less striking than is the apparent repetition of attacks of facial zoster, yet he would seem to regard the inflammation as erysipelatous in character, and he fails to mention scarring as remaining after one attack. Reference is not made to scarring resulting from herpes frontalis in his work, yet it is well known to be the rule, and this dermatological landmark must, in some of his cases at least, have been overlooked.

Herpes zoster is a neuralgic disease of the affected nerve branches—in this instance those of the fifth. The neuralgia always precedes for a variable period the cutaneous inflammation; it is always limited to the known distribution of the affected nerves; it is almost invariably accurately limited by the median line; the attack is not accompanied by constitutional symptoms.

The eye complication is peculiar to neuralgia of the ophthalmic nerve.

The above are sufficient to differentiate any case of facial zoster from erysipelas, for they are present—with the exception of the eye complication—before the cutaneous inflammation appears.

After the latter is present in zoster it closely follows the distribution of the neuralgia; in erysipelas it abhors any limit. The vesicles, when present, also follow only the distribution of the diseased nerves; are usually smaller, more numerous, and grouped: very different are the erratic and fewer bullæ of erysipelas. The vesicles and their débris remain from one to many weeks in zoster, the pain, though frequently abating when the eruption appears, still being usually present.

After the scabs drop off, in the young, an injection of the vessels over the seat of the eruption does not usually disappear for many more weeks; whereas in the aged, whose reparative processes are on the wane, we may have actual and persistently painful ulcers.

The patient who has once suffered from a typical attack of herpes zoster carries around with him, and may be recognized years afterward by, the permanent, depressed, punched-out, pit-like, white, discrete, and grouped cicatricial scars covering the former seat of the disease.

The scars are most distinct over the regions where the soft, subcutaneous tissues are most plentiful, viz., over the median frontal region and hairy scalp, also over the temporal region and the eyebrow. They are least marked, and almost imperceptible, over the thin, fine, skin of the eyelids.

Lastly, the neuralgia that is least marked in the youthful patient, and may remain with him a variable period of a few days, weeks, or months, may, in the aged and feeble, end only with the termination of life.

The remaining anæsthesia of the skin in the region of the affected nerve-districts has been already mentioned, and we have only to add that the eyeball when inflamed is also left in a more or less markedly anæsthetic condition.

With such a picture is it possible to confound this disease with erysipelas?

It seems more incredible to think that a neurologist of Anstie's calibre could have seen any relationship between the cutaneous inflammation of trigeminal neuralgia and that of ordinary erysipelas, which loathes any limit—anatomical or clinical—than it is for ourselves to believe that his second reported case was a true example of zoster frontalis, in whom there appeared three separate attacks of this disease.

That it was not a case of ordinary erysipelas few will deny. In the first attack the "erysipelas was accurately limited to the right half of the face." This speaks in favor of zoster, yet by no means is it impossible to have the limit of an attack of erysipelas to one or other side of—though not likely to be "accurately limited" by—the median line, which it is so prone to transgress on the face.

About four and a half years after the first attack, and preceded for a period of fifteen or sixteen days "with violent intermittent neuralgia," a second "attack of erysipelas strictly limited to the district of the painful nervous branches then set in." Yet another "attack of erysipelas occurred some three or four weeks after the first," and "the neuralgia disappeared about four months after its first occurrence. The pain was accompanied by intense conjunctival congestion and photophobia," and the eye was practically lost, for ophthalmoscopic examination was impossible.

Zoster has been mistaken for eczema in its vesicular stage, but the mere mention of the fact is all the interest it possesses for our study; a careful observation will readily prevent such an error.

Anstie reports other cases which illustrate the steps from the ordinary keratoiritis to the complete double glaucoma following, and the result of trigeminal neuralgia.

These, together with the case of my own patient, though not warranting a positive opinion, yet lead me to the belief that the character of the ocular inflammation of neuralgic zoster is *serous*, and though we have in the cases of our study evidences of posterior synechia, yet in cases of so-called serous iritis we may have present sufficient plastic material thrown out to agglutinate the *posterior* surface of the iris to the lens capsule.

I consider that the iritis is *serous*, and with a marked tendency to extension of the inflammation to the ciliary body, and still further to the choroid, and that, owing to

a vaso-motor paralysis only, or together with the influence of the special set of trophic fibres bound up in the trigeminus, and referred to elsewhere, we have a dilatation of the ocular blood-vessels with serous inflammatory exudation into the vitreous chamber, causing an increased intra-ocular tension, resulting, if sufficient, in inflammatory glaucoma in a proportion of the cases.

If this be so, its bearing on the management of the ocular complication of cases of zoster frontalis is obvious—so that, if possible, previous to the iritis, or, at least, previous to the glaucomatous condition, we may, by resort to prophylactic treatment, prevent, if possible, the onset of the latter disastrous result.

Before referring to treatment of zoster frontalis, a word more may be written on the character of the pain present in these cases, on account of its bearing on the matter of prognosis.

In our fifty-two cases neuralgia is mentioned in twenty-six as being more or less severe; in the remaining cases, in many of which the notes are too brief, because unobtainable, to call histories, the pain is not referred to. The pain was of a lightning-like character, paroxysmal, came unexpectedly, and was gone as quickly. It preceded, for some time, the eruption, and was localized to the affected nerve-districts, and lasted, after the acute stage of the complications, a variable period—speaking generally, the shortest time in the youthful patient, and the longest period and most severe in the aged. In one case it was present six years afterward, in another four years, and in Trousseau's cases five and fourteen years respectively. For this distressing symptom alone some sought advice.

Anstie writes (p. 54): "I have known one patient, a woman over seventy years of age, absolutely killed by the exhaustion produced by protracted suffering of this kind."

As to the degree and importance of the pain at different periods of life, Anstie says: "Painless herpes is commonest in youth. From the age of puberty to the end of life the tendency for herpes to be complicated with neuralgia becomes progressively stronger," and, referring to its recurrence after the cutaneous outbreak, he further writes: "In old people it almost always does return, and often with distressing severity and pertinacity. Six weeks or two months is a very common period for it to last, and in some aged persons it has been known to fix itself permanently, and cease only with life."

Treatment.—The general and main treatment of herpes frontalis is undoubtedly that of the neuralgic state on which it depends. Therefore, in all cases—whether peripheral or central in origin—we must treat this disease by properly selected constitutional methods.

Cod-liver oil, strychnia, arsenic, and iron are all useful. Quinine is valuable in these cases, and Anstie says: "It is a fact that quinine does benefit ophthalmic neuralgias where there is no room for suspicion of malaria." He recommends two-grain doses three times daily. At any period of the disease hypodermics of morphia, together with chloral and bromide of potassium for their hypnotic effects, are valuable as temporary aids in the treatment of the neuralgia.

For the skin complication topical treatment is required, and among the best remedies are sedatives and those which exclude the air, "by which we seek to mitigate the paroxysm" of pain at its apparent site. Anstie says: "Very much the best agent of this kind is the flexible collodion. In neuralgic herpes and erysipelas the effect of this agent, conjoined with the hypodermatic injection of morphia, is of the greatest possible service in mitigating the pain. In herpes it prevents the occurrence of sores after the vesicles fall," frequently troublesome in the aged, "and which very much increase the severity" "and intractability of the consecutive neuralgic pain." To the ordinary flexible collodion the addition of the local anæsthetics, iodoform and the more powerful, though less permanent, hydrochlorate of cocaine would seem to increase the anodyne results. The latter remedies might, however, be used in solution, and applied when needed for the pain. Ether in the iodoform solution would increase its effects. A cap of cotton, that was found useful in one of Bowman's cases, covering completely the painful nerve-districts, would probably be a serviceable addition to these remedies.

Anstie also suggests the application over the painful nerve-districts of the tincture of aconite, or veratrine ointment, only in those cases where the skin is unbroken after the inflammation has passed entirely away, or in those cases where the skin was not complicated.

Speaking of blisters in neuralgia, Anstie considers Valleix's assertion, "'that they are the best of all remedies,' is not very wide of the truth," though not universally applicable. He agrees also with Valleix that "flying blisters" are preferable to the plan of keeping the blistered surface open and irritated. Anstie regards blisters as "true stimulants of nerve-function," and in order to thus act "it will be necessary that the skin irritation be either produced at some distance from the seat of greatest pain, or if applied in the spot it shall be comparatively mild in degree." He, therefore, applies "the blister at some distance from the focus of pain," but in choosing the site "there must be an intelligible channel of nervous communication between the irritable portion of skin and the painful nerve."

Blistering, however, is a remedy which is not well suited to aged subjects, and for such the "continuous applications of moist warmth," together with the use of chloroform liniment and mild rubefacient remedies, are to be preferred. Anstie speaks in the highest terms of the value of galvanic electricity, but does not favor Faradism in true neuralgias.

Now we come to the discussion of surgical interference in those cases where the neuralgia, in spite of all previous methods of treatment, still persists, rendering even life itself irksome to our unfortunate patient.

Again to Anstie we look, who says, in speaking of resection of nerves: "Neuralgias of the trigeminus are pretty nearly the only cases in which the proposal of neurotomy or neurectomy ought to be entertained. Resection of painful branches of the trigeminus has been performed in a great number of instances, more especially by German surgeons, with results that merit our attention. On the other hand, with the exception of simple division of the nerve, which can be subcutaneously performed, and is a trivial proceeding (but has very short-lived effects), these operations are by no means without danger, especially where they are pushed to such a length as the opening of bony canals and the resections of considerable portions of bone, in order to get sufficiently far toward the centre, and fatal results have in more than one case followed."

We have had three different opinions expressed as to the seat of the origin of the neuralgia in these cases of zoster frontalis—Bowman considering examples of this disease to be mainly of peripheral origin and extent; Hutchinson thinking them to be in the majority of instances central, yet considering those few of extremely limited area most probably peripheral, whereas Anstie regarded every true neuralgia of central origin, and therefore justly objected to surgical interference in any of them.

On the seat of the disease will depend the result of surgical procedure in any of these cases. In those cases of recognized central origin neurotomy or neurectomy is most certainly contraindicated, yet in those cases of essentially peripheric origin and extent—and we believe with Hutchinson that there are such—they would seem to be as essentially desirable.

Unfortunately we have no accurate means of differentiating between the two kinds of cases.

Those instances of zoster frontalis occurring in the aged, especially with a previously neurotic history, and again associated with secondary motor paralysis, are

almost certainly of centric origin. Those cases also of severe disease, involving a large area—not only all the branches of the ophthalmic, but also implicating the second or even all three divisions of the fifth nerve—are most probably of central origin.

Whereas those cases occurring in the first half of life, in previously non-neuralgic patients, with a recent history of exposure to cold, damp wind, and with a continuous pain, together with disease of limited extent, involving, may be, only a few terminal filaments of one or more branches of any one or more divisions of the fifth, will most probably prove to be instances of peripheral origin and extent.

Further than these indications we cannot go at present.

Seeing, however, that it is conceded by our three authorities, and an accepted fact of our day, that subcutaneous section of superficial sensory nerves is a riskless and simple procedure, and painless under anæsthesia; therefore, in those instances where we have any doubts as to the character of the case, a division of one of the nerve-branches would seem to be indicated as a test of the seat and extent of the disease. This having been done, and the patient again conscious, if the pain has now ceased in the region of distribution of the divided nerve-branch, and palpation over the same area does not cause its return in that or other districts, we may justly consider the case to be one of peripheral extent and origin, and after again anæsthetizing our patient, proceed, as far as the same is possible, to exsect a portion of each of the affected nerve-branches.

In those cases where the pain persists after our experimental division of the nerve it would seem wiser to desist from further operative procedure, and treat the patient according to the best methods suggested to the mind of the physician in charge.

Limited by our study, therefore, we believe that exsection in the properly selected cases offers the most rapid and permanent relief from the persistent neuralgia of zoster frontalis, and that in the hands of the educated clinician—not loaded down with the heavy weight of the uncertain pathology of these cases—it is likely to gain a permanent and worthy stand.

The treatment of the eye complication is as yet untouched, and calls for a few remarks. Hutchinson, as far as I can find, does not refer to ocular treatment, and Bowman's remarks are unsatisfactory.

Whether on account of vaso-motor paralysis through palsy of the sympathetic, or on account of certain fibres of the trigeminus being active ones of secretion, we know not, yet we believe that the characteristic quality of the eye complication of zoster frontalis or trigeminal neuralgia is one of serous inflammation of the affected tissues, resulting in a variable increase—according to the grade of the inflammation—of the intra-ocular fluids. The same increase may be only of slight amount and temporary, causing no organic harm. In those instances of severe disease there appears to be a tendency to implication of the deeper tissues of the ball, resulting in such an increase in the intra-ocular fluids that the same are formed more quickly than removed; hence we have a steadily increasing intra-ocular tension resulting, if not relieved, in glaucoma in a few instances, and a more or less complete destruction of the organ by the same, or by secondary trophic changes, the sequelæ of the inflammation.

Appreciating the danger, can we not anticipate the same by proper prophylactic treatment in those cases seen previous to the onset of the ocular complication? Again, in those cases where the eye-inflammation has already commenced when first seen, can we not limit the extension of the same so that the deeper tissues of the eyeball may escape and the eye be saved? Yet again, in those cases where the glaucomatous condition is already present, can we stay the progress of the same with the hope of having a maimed, instead of a completely destroyed, eye.

A remedy, in order to achieve the desired results, must be one that will reduce the calibre of the paralyzed ocular vessels and thus limit the production of the intra-ocular fluids; again, if possible, it must unlock the outlet so that the excess of fluid may escape from the eye. To be of prophylactic use it must prevent the vascular dilatation and keep the drain open.

In eserine we find the remedy that, *par excellence*, achieves the above results. This remedy may already have been recommended in these cases, but if so it is unknown to the writer.

As a prophylactic its occasional use, in the form of ointment, is advisable; after the keratitis is present it will need to be used more frequently, together with the general treatment for the same; in cases of keratoiritis, or iritis, it may still be used, but on account of its irritant effects the result must be watched. If the intra-ocular tension becomes plus normal and the iritis and ciliary neuralgia are increased by its use; again, in those cases where, together with an active iritis, we have extension of the inflammation to the deeper tissues of the uveal tract with increasing tension under its use, we must withdraw the remedy and either resort to paracentesis of the cornea, or, if the integrity of the eye is endangered, iridectomy may be considered advisable.

Yet in the majority of instances we anticipate that eserine—especially as a prophylactic and in the very earliest stages of the ocular inflammation—will be found an unmixed good. In our own case it has been used without the slightest irritant effects, and the neuralgia of the eyeball has ceased entirely, the sclerotic is paler and more opaque, the tension is lowering, the cornea and media becoming clearer, his vision showing signs of improvement, the fundus seen more clearly, and the vision of the fellow-eye has risen in eleven days from $\frac{20}{XXX}$ to normal.

In the hydrochlorate of cocaine we have the most powerful local anæsthetic and vessel contractor, and its slight mydriatic action, together with its slight paresis of accommodation effect, may not be especially injurious in these cases. In those cases where eserine's irritating action is pronounced, in the cases of iritis, or in those cases of deep inflammation, it would seem that the hydrochlorate might be used before resorting to operative procedures. Its effects, as thus far investigated, are very transient, and we know not as yet whether its frequent application—as would be needed in these cases—can be fearlessly pursued. In a few cases recorded it would seem that occasionally its effects are not entirely intra-orbital, for, besides the local action, marked pallor of the skin, together with beady perspiration and threatened and actual syncope, has been observed. If due to the drug, probably an anæmiating effect is produced on the nervous centres, though Dr. J. L. Minor [1] attributes these symptoms to the conscious fear of the patient when an operation is going to be performed, and the latter is undoubtedly a facile explanation.

Is atropine a remedy suitable for this form of eye-inflammation? "According to the most recent and reliable tonometrical investigations, atropine diminishes the intra-vascular tension by paralyzing the muscular coat of the vessels, but the general intra-ocular tension in the vitreous is increased by its use" (Bull).

Any remedy producing such results, in our opinion, ought to be entirely avoided in the eye complication of trigeminal neuralgia, lest we precipitate the result that we endeavor to avoid, viz., glaucoma, by not only increasing the intra-ocular fluid, but also by damming up the iritic angle and Fontana's space, and thus blocking the drainage system of the eye.

My own patient states that atropine was used twice daily, in the early stage of his eye disease, for one week. During the latter two days of this time the suffering following its application, together with the marked reduction of vision, caused the surgeon to interdict its further

[1] See M[illegible]

use. After its effect passed off, he says the eye became comfortable and the increased cloudiness disappeared. If used at all, it should be only for diagnostic purposes, and only by those skilled in ophthalmic practice.

Before closing this unexpectedly prolonged study, and as an apology for the same, a word about the frequency of herpes frontalis may be added. Hutchinson says: "The disease is, I am persuaded, more frequent than is generally supposed. In proof of this I may mention that, during the last year, no fewer than three patients have consulted me in private on account of its effects." Again, he says: "I have found most surgeons very incredulous as to this disease, and I free in their assertions that they had never seen it, and that it must be extremely rare. My conviction is that it is misnamed."

Again, the impulse of which this study is the result was created by the fact that my own patient had gone unrecognized for nearly five months, and had been seen by four different practitioners. The first recognized the herpetic eruption, knew it was not erysipelas, yet asked the patient if he had ever had syphilis; the second recorded "herpetic condition of the lid;" the other two—both specialists—recognized the iritis; but all overlooked the trigeminal neuralgia.

Conclusions.—From the foregoing study it would seem that the phenomena of herpes zoster frontalis are dependent upon, and the result of, the neuralgic disease of the ophthalmic division of the fifth cranial nerve; that the essential condition is one of asthenia of the nervous tissues involved; that there is no definite or constant anatomical change in the affected nerves; that in the great majority of instances the disease is of central origin, but that in a few cases it appears to be of peripheral origin and extent; that the associated cutaneous and ocular inflammations are secondary to the neuralgic disease, and appear subsequently to the onset of the same; that these dependent inflammations are due to vaso-motor paralysis on account of palsy of the sympathetic, or due to the influence of a special set of trophic fibres embodied in the trigeminus; that the extent and severity of the inflammations are in direct relation to the severity, extent, and persistence of the neuralgia; thus we may have any degree of increased vascularity or inflammation—from simple hyperæmia to complete destruction of tissue.

The essential treatment of the disease is that of the neuralgic state; that in the instances of central origin local surgical interference is contra-indicated, but in the fewer cases of peripheral origin and limited extent, excision of the affected nerve-branches is advisable; that the ocular inflammation is serous in character, with a special tendency to increased intra-ocular tension and the glaucomatous state; that on this account eserine would appear to be the remedy *par excellence*.

The disease, though almost invariably occurring but once in a lifetime, and also, almost invariably, accurately limited by the median line of the body, may, in very rare and exceptional instances, not only transgress for a short distance the median line, but also occur more than once in the same individual.

That it is a disease occurring with greatest frequency and most severity in the latter half of life; that it is a disease important, not only on account of the destructive ocular inflammation, the severe and often prolonged suffering, but also on account of the risk to the life of the aged patient; that it occurs more frequently than is generally supposed; that it is often misnamed, and hence overlooked.

ANTIPYRIN AS AN ANALGESIC IN HEADACHE.

Dr. John Blake White, Physician to Charity Hospital, New York, sends us the following:

"The high road to truth is the knowledge of facts, and well is it for searchers after truth when facts can be ascertained and carefully recorded.

"Symptoms are the alphabet, cases the language, of disease, and that physician subserves his profession who carefully records his experience.

"During the past two years I have abundantly tested the therapeutic value of the drug known as antipyrin in various forms of headache. The prompt relief obtained through its use compels me to accord to it a high rank among our medical resources. I have already called attention (*Medical News*, July 10, 1886) to the potent antipyretic power possessed by this remedy in the management of various forms of fever, and have observed that after its administration the urgent symptom of headache, so uniformly present in these cases, was soon controlled.

"Antipyrin undoubtedly possesses bradycrote properties in a high degree, as the pulse is notably softened and moderated in frequency soon after a proper dose of it has been taken. It produces some somatic change favorable to a reduction of the pulse in cases of fever, and so exerts a calming influence upon the vaso-motor system. The capillaries, through its agency, doubtless dilate, and local congestions are dissipated, as the relieved patient usually sinks into a refreshing repose soon after its exhibition. In the course of large experience with antipyrin I have found that, when administered in masterful doses, it not only promptly relieves the symptom of headache whenever present, whether resulting from disordered digestion, disturbance of the menstrual functions, loss of sleep, undue mental effort, or even that associated with dreaded uræmia, but also possesses reliable prophylactic virtues against recurrent attacks of cranial neuralgia. So confident am I of the power of this remedy to disappoint neuralgic headache when imminent, that I have instructed many patients, who are liable to such visitations, to keep in readiness and take a dose of antipyrin as soon as they have premonition of its recurrence, and all so far testify in favor of its efficacy.

"The value of this remedy in the above respect has not only been tested in my hospital and private practice, but I also record the fact that it has proved successful in the hands of professional friends, upon whom I had urged its employment for the relief of neuralgic affections of the head and face. I have been singularly impressed with the promptness of relief which often followed the administration of even a single dose of fifteen grains of the antipyrin. The grateful relief from headache usually ensues within half an hour after the drug is taken. A sense of drowsiness ordinarily supervenes, followed by a brief but sufficient slumber, and the patient awakens quite relieved of this distressing symptom. I have never yet seen the sleep-disposing properties of antipyrin alluded to by any other observer, although this effect seldom fails to ensue when a full dose such as I have named has been taken."

The newly formed State Board of Health of Massachusetts has been organized by the appointment of the following members by the Governor: Dr. H. P. Walcott, of Cambridge, chairman; Dr. F. W. Draper, of Boston, medical examiner; Dr. E. A. Jones, of Taunton, homœopathist; Julius H. Appleton, of Springfield, manufacturer; Thornton K. Lathrop, of Beverly, lawyer; Hiram F. Mills, of Lawrence, civil engineer; James White, of Boston, retired merchant.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, September 11, 1886.

ANOTHER NEW ANTIPYRETIC-ANTIFEBRIN.

IT would seem as though there were already a sufficient number of antifebrile remedies to satisfy the most enthusiastic therapeutist, but the list is being added to almost daily, and the clinical mine shows as yet no signs of threatened exhaustion.

The latest discovery in this direction is announced by Drs. Cahn and Hepp, of Strassburg, in the *Centralblatt für klinische Medicin* of August 14, 1886. The substance is known chemically as an acetanilid or phenyl-acetamid, the formula for which is $C_6H_5NHC_2H_3O_1$, but the writers have given it the more convenient name of antifebrin. It is a clean, white, crystalline, odorless powder, imparting a slight burning taste when placed on the tongue. It is almost insoluble in cold water, dissolves with difficulty in hot water, but freely in alcohol and alcoholic liquids, such as wine. It melts at 235.5° F., and sublimes unchanged at 557.5° F. It possesses neither acid nor basic properties, and is very rebellious to the action of most reagents.

The authors have experimented with the remedy in a number of febrile troubles—among others typhoid fever, erysipelas, acute articular rheumatism, pulmonary phthisis, and septicæmia—and state that the results obtained were very satisfactory. It is given in doses of from four to fifteen grains, shaken up in water, dissolved in wine, or enclosed in wafers. A maximum dose of thirty grains per diem was not exceeded. In general terms it may be stated that it is of about four times the strength of antipyrin. The effect of the drug upon the temperature is noticed at the end of about an hour, and attains its maximum usually in about four hours, passing off again, according to the size of the dose, in from three to ten hours. The action of antifebrin manifests itself externally by a reddening of the surface and moderate perspiration. The patients sometimes complain of a cold feeling, though there was never any decided chill noticed. The pulse-rate falls proportionately to the temperature. There was never any nausea caused by even large doses.

In conclusion, Drs. Cahn and Hepp speak enthusiastically of the marked antipyretic properties of the new drug, and of the absence of any untoward symptoms attributable to it. It has also, they claim, the advantage of cheapness, being obtainable for the moderate price of about twenty-five cents an ounce at wholesale.

PHYSICIANS AND INSURANCE CERTIFICATES.

SOME days ago the daily papers noticed an instance where a physician was accused of assigning a wrong cause of death on an insurance certificate, for the purpose of collecting the amount of the policy for the benefit of the patient's friends. The accused person was able to completely exonerate himself from the charge. The fact, however, of such circumstances having arisen, calls attention to the methods of business pursued by some life-insurance companies, which are worthy of severe condemnation. These methods are embarrassing to the physician, but of especial unfairness to the insured.

We do not refer to the large companies with their enormous legitimate business, where the risk of each individual case is carefully considered before any policy is written, and where the relation between present age and chances of long life are computed from carefully prepared tables of vital statistics. The laws of insurance are compact, and the companies manifest no desire to evade any of their responsibilities; but we have reference to some of the smaller industrial insurance organizations. Their policy seems to be to take any risk, however great—that is, they get all the premiums they possibly can; then, if, at the time of death of the insured, they can prove that he or she had any chronic disease, they try to evade the full payment of the policy.

Among many of the poorer classes the small amount of their insurance means a great deal. Their wages and the cost of living allow of no savings. The policy practically represents a burial fund. About this, least of all, should there be any haggling by the companies, or any delay in its prompt payment. A physician may be called in to see a patient in the last stage of phthisis. The patient dies, and the medical attendant is called upon to certify whether the patient was afflicted with any chronic disease. If he is honest, he must answer yes, though he knows that this will result in a partial or entire forfeiture of the amount of the policy. If the company was not willing to pay the whole amount in case of death from any cause, it should not have taken the risk. The persons thus exposed to injustice are those whose lack of means prevents them from resorting to legal redress. The agents of some of these companies are irresponsible persons, whose business methods are hardly to be commended. In this great city there is a large enough field for legitimate business, even among industrial organizations. There is no need of their taking extra-hazardous risks. Still less is there justification for their receiving premiums and then refusing to fulfil their part of the contract.

THE EXCRETION OF DRUGS BY THE MAMMARY GLANDS.

A GOOD many observations have been made upon the subject of the medicines excreted by the mammary glands. It has been claimed that mercury, iodine, bromine, arsenic, strychnine, chloroform, sulphur, and chloral may be thrown off by this gland when taken into the stomach of the nursing woman. It cannot be said, however, that our knowledge of the subject is as complete and definite as it should be, and hence the recent experiments by Fehling are of interest. Fehling observed the effects on nurslings of various drugs given to the

nursing mothers. According to the Paris correspondent of the *British Medical Journal*, when doses varying from two to three grammes of salicylate of soda were administered to the nurse, every time that a child was suckled within an hour after the administration of the dose the salicylate appeared in its urine. After an interval of twenty-four hours there remained no trace of the drug. When the child was suckled too soon after the medicine had been taken, the salicylate could not be found in its urine. Elimination was completed at the same time in the mother and the child. With iodide of potassium the results were the same. The milk, when analyzed, gave the characteristic reaction. In the infant, elimination lasted seventy-two hours, in the mother forty-four. After twenty-four hours the milk still contained iodide of potassium. With ferrocyanide of potassium reaction was very pronounced in the maternal urine, but absent in the child's. Prolonged applications of iodoform upon vaginal and vulvar wounds of women in parturition, after prolonged use, generally resulted in iodine being found in the milk and urine of the mother, but not always in the urine of the infant. The child was never indisposed, even when iodoform was used to dry up the umbilical cord. There was only a small quantity of mercury transmitted through the milk of a nursing mother, and its presence was not constant. It appeared that the food of wet nurses—even acid fruit-juices and vinegar—had no influence on their nurslings. Thornhill had stated that he observed prolonged sleep occur to children after administering to their wet-nurse such narcotics as tincture of opium in doses of from twenty to twenty-five drops. Fehling observed neither prolonged sleep nor constipation in the children. Hydrochlorate of morphine or chloral, in tolerably strong doses, did not affect the sucklings. Subcutaneous injections of moderately strong solutions of sulphate of atropine produced very pronounced symptoms in the mother, and dilatation of the pupil in the infant, which disappeared in twenty-four hours. This substance should, therefore, be employed in very feeble doses. In a very great majority of cases the milk of a woman attacked with fever had no influence upon the nursling. In those rare cases when the temperature reaches 104°, the variations in the child's temperature were identical with those of the mother. In some instances children had died of intestinal catarrh where the mother's milk could be the only cause of the affection. Bumm has observed, in a case of inflamed breast, the passage of the micrococcus from the milk into the digestive apparatus of the child.

CHARLESTON PHYSICIANS IN GREAT NEED.

In the telegraphed reports of the calamity which has visisted Charleston much is said of the general distress which prevails, and instances of individual suffering are related, but we do not remember to have seen any mention of the trials of the physicians. As is usual at such times, they have been silently going about doing good and administering to the needs of others, while themselves homeless and ruined. Yet the wants of the business classes and of the laborers and others are telegraphed abroad, and appeals for help for them are made, while the physician, too busy in his work of mercy to think of himself, is [illegible] without a word of recognition or even thanks.

We are permitted to present the following extract from a private letter from one of Charleston's best known physicians to a medical gentleman in this city:

"We are distressed," he writes, "almost beyond endurance. Our women and children are our sources of anxious solicitude. May God protect them in the open field, tenting in the night air! My entire family—wife and four children, the oldest eleven years of age—are out of house and home, like hundreds of other sufferers." . . .

We think little more need be said to show the necessity of speedy aid for the sufferers among our own brethren in Charleston. There are no doubt many cases of individual want among medical men and their families, for while their services are in demand, and they are busied in attending to those suffering from injuries and the results of exposure, yet they are seldom paid, at least in cash. Their families are homeless and must be provided for, but food and shelter are not to be obtained without ready money in such times, and ready money the physician but rarely obtains.

We therefore appeal to our readers throughout the country to help their brethren in South Carolina in this their hour of need. We are accustomed, by our very calling, to help others when in distress, and let it not be said that we are indifferent to the sufferings of those in our own ranks. Now is the time to help them, and he who gives quickly gives twice. THE MEDICAL RECORD will gladly receive subscriptions for this object, and will forward the amounts so received at once by telegraph. Acknowledgments will be published in our next issue.

News of the Week.

A FATAL AFFAIR.—A coroner's inquest was held short time ago on the body of a woman who, it appeared, had been suffering from heart disease, and this bringing on a fit of despondency she had taken a dose of Paris green. The coroner's jury found that the woman had died of "heart disease accelerated by partaking of a dose of Paris green."

DEATH FOLLOWING AN APPLICATION OF COLLODION.—A death is reported in France from the application of collodion to the face of a woman suffering from small-pox. The design of the application was to prevent pitting. Suppuration took place under the mask of collodion, and the patient died after great suffering. As the small-pox was discrete and uncomplicated, and the autopsy showed no visceral lesions, the fatal termination would seem to have been due to the injury resulting from the collodion.

DEATH FROM ETHER.—Mrs. Mary S. Wesselhoeft, forty years of age, said to have been the wife of an American physician, was found dead in her bed in London on August 5th. According to the evidence of her husband, given at the inquest, it appeared that the deceased had suffered from asthma, for the relief of which she was supplied with ether. A pint bottle, two-thirds full of the drug, was found by the bedside, and the atmosphere of the room was charged with the vapor of ether. The jury returned a verdict in accordance with the medical evidence,

and expressed the opinion that it was unwise to have allowed the deceased to have so much ether at her command.

HOSPITAL SATURDAY IN ENGLAND.—At the board meeting of the Hospital Saturday Fund, held on August 7th, it was reported that, notwithstanding the unfavorable state of the weather, the Hospital Saturday street collection had realized £4,000; being £500 less than the amount obtained last year.

HONORARY DEGREES FROM HEIDELBERG.—Upon the occasion of the recent celebration of the five hundredth anniversary of the University of Heidelberg, the honorary degree of Doctor of Medicine was conferred upon Graham Bell, of Washington; Professor Chevreul, of Paris; Baron Nordenskjöld, of Stockholm; Sir William Thompson, of Glasgow; Professor Roscoe, of Manchester, and others. Professor Koch, of Berlin, was created Doctor of Philosophy.

PROFESSOR VON LANGENBECK has been suffering for some time from failing vision due to a cataract. He recently submitted to an operation for its removal at the hands of Dr. Pagenstecher, of Wiesbaden. The operation was entirely successful. Many friends, including the Emperor and Empress of Germany, have sent telegrams of congratulation to the eminent surgeon.

"WHO WILL BE THE FIRST TO TACKLE A WEN?" The question is answered by the following, clipped from a recent issue of the *Buffalo Express*: "Yesterday afternoon, Dr. —— performed a skilful operation in the removal of a large *follicular tumor*, several ounces in weight, from *the head* of Mrs. L ——, of this city, who has for many years suffered great pain from its continued growth and pressure under the scalp." What next?

A CASE of yellow fever from the steamer Alvo, of the Atlas Line, found its way into St. Vincent's Hospital on Saturday last. The disease was duly diagnosticated, and the patient transferred to the Reception Hospital, where he died.

THE DEATH OF DR. THEODOR JURIÉ is announced from Vienna. He was born in October, 1809, and began the practice of medicine in 1834. He celebrated his jubilee two years ago, upon which occasion, among other honors, the Emperor of Austria conferred upon him the title of nobility, creating him Edler von Lavandal. His death was caused by embolism of the cerebral arteries. He left two sons, both practising physicians in Vienna.

ANOTHER SUCCESSFUL CASE OF LAPAROTOMY FOR INTESTINAL WOUNDS.—It is stated in *Dance's Texas Medical Journal* that Dr. Bacon Saunders, of Bonham, Tex., has operated twice for wounds of the intestines, and once with success. These cases have never been recorded, but a report of the operations is promised by Dr. Saunders.

THE RELATION OF HEIGHT TO WEIGHT.—According to Dr. Broca, the well-known French anthropologist, the human body should weigh as many kilogrammes as it measures in centimetres, after deduction of the first metre. Thus a man measuring one metre eighty centimetres (six feet), should weigh eighty kilos (176 pounds). Should his weight be more or less, he is too stout or too thin.

DEATH FOLLOWING AN INTRA-UTERINE INJECTION.—Dr. Otto Engström reports in the *Finska Läkaresällskapets Handlingar*, Nos. 5 and 6, vol. 27, the case of a woman, thirty-seven years of age, who was suffering from fungous endometritis. The mucous membrane of the uterus was curetted and then an injection was made of a solution of iodine, one part to thirty of water. After the second injection, which was made with a stronger solution (1 to 10), the patient had a chill which was followed by symptoms of peritonitis, and death occurred three days later. There was no evidence at the autopsy of any fluid having passed through the Fallopian tubes, and the writer believed that the inflammation of the peritoneum arose by extension from the uterine substance.

Obituary.

THOMAS ALEXANDER McBRIDE, M.D.,

NEW YORK.

THE many friends of Dr. McBride were shocked to hear of his untimely death, which occurred at sea on Tuesday, August 31st. During the past year, although he kept actively at work, he was far from being a well man. The symptoms of Bright's disease, from which he had been suffering for a considerable period, became more pronounced, and he was forced to go abroad for rest and treatment. He spent the greater part of the summer at Carlsbad, with the result of a temporary improvement; but after reaching Southampton on his return homeward he was seized with uræmic coma, and died on the second day of the voyage. His body was committed to the deep with appropriate funeral ceremonies, the Rev. Dr. Buell, of St. Luke's Church, New York, officiating.

He was born in Sandusky, O., in 1844, and was at the time of his death forty-two years of age. After completing his early education in his native State, he matriculated in the College of Physicians and Surgeons of New York, and graduated in medicine in 1871, immediately thereafter entering Bellevue Hospital and serving his interneship in the medical division. He then commenced practice in New York, where he rapidly gained an enviable reputation for studious research, for accuracy in diagnosis, and skill in therapeutical resources. Devoting himself to renal and nervous disorders, he soon rose to a high rank as a consulting physician in these branches. With a peculiar aptitude for applying the results of recent discoveries to practice, he was considered to be one of the most accomplished practitioners of the day.

Notwithstanding the demands of a large business, he found time to keep abreast of all the advances in his department, and by his numerous and well-digested medical papers to add the results of his personal observations, oftentimes astonishing his friends with the variety and profundity of his knowledge of the most abstruse questions in our science. Many of these papers he contributed to the *American Journal of Neurology and Psychiatry*, of which he was for a long time the editor-in-chief. He was for several years attending physician to Bellevue Hospital, and at the time of his death attending physician to the Presbyterian Hospital, lecturer on clinical medicine at the College of Physicians and Surgeons, and member of the following: The Medical Society of the County of New York, the New York Academy of Medicine, the Laryngological, Neurological, and Practitioners Societies; also of the University and New York Yacht Clubs.

Of a genial temperament and generous spirit, he endeared himself to a large circle of friends, in whose memories will linger the recollections of a lovable and well-spent life.

Reports of Societies.

British Medical Association.

FIFTY-FOURTH ANNUAL MEETING.

Held at Brighton, England, on Tuesday, Wednesday, Thursday, and Friday, August 10, 11, 12, and 13, 1886.

MEETINGS OF SECTIONS.

SECTION IN OBSTETRICS AND GYNECOLOGY.

WEDNESDAY, AUGUST 11TH—SECOND DAY.

PRESIDENTIAL ADDRESS.

DR. MEADOWS (President of the Section) took the chair at 2 P.M., and delivered an address. In his opening remarks Dr. Meadows drew the attention of his audience to the wide separation that was steadily taking place between gynecology and obstetrics. It was true that in the minds of some the two departments were still indissolubly linked, but the divorce had really taken place, and with the rapid development taking place in our knowledge of these arts, the gap must become more and more marked. The enormous advances made in gynecology had riveted the attention of the medical world on the practitioners of this branch of medicine; the marvels of ovariotomy and the great strides made in other departments of abdominal surgery were among the greatest triumphs of skill the world has ever seen. In no other department of medicine had so much been done to save human life and successfully alleviate human suffering. Referring to the discussion that was to take place on the "Alternatives to Craniotomy," Dr. Meadows condemned the latter operation in the severest terms, and trusted the day was not far distant when destruction of infant life by the perforator would be a thing of the past. No words could be too strong when used against an operation the practice of which was opposed to every sentiment of religion or morality. The operation had been held in check in former times by the religious feeling of the age, and the same voice still condemned so coarse and barbarous a proceeding. It was to be hoped that in the time to come living children would always be secured by the operation of Porro or by Cæsarean section. To the gynecologist will be due the credit of saving infantile life, and in this respect he stands far in advance of the obstetrician. The facility with which craniotomy can be done will always be a temptation to use it instead of resorting to the Cæsarean section or to Porro's operation, and unless a feeling of deep moral responsibility is uppermost in the practitioner's mind the obstetric art will be still disgraced by the frequency with which embryotomy is practised. Speaking of the papers that were promised on the subject of "Removal of the Uterine Appendages," the President entered his protest against such a misapplication of terms; the uterus and the Fallopian tubes ought to be spoken of as the appendages of the ovaries, and not *vice versâ*. The removal of the uterine appendages was an operation which was rapidly rising into importance, and must occupy the thoughts of every serious mind; it was much to be regretted that so much angry feeling had been imported into this matter, but it must be remembered that great advances were always attended with great opposition. Perhaps, if the Section could imagine some operation suddenly brought forward to deprive the male sex, in a similar way, of the testicles, an idea could be obtained of what an outcry would certainly be raised; as it was, placed outside the pale, the superior sex could look on unprejudiced and weigh the matter calmly. Dr. Meadows held that removal of the uterine appendages was a most useful operation, and commended its employment in certain cases of neurotic disease, in cases of uterine fibromata, and also in extreme instances of pelvic distortion, where the birth of a living child was impossible. In these latter cases removal of the uterine appendages was preferable to Porro's operation, the induction of premature delivery, etc. A word of warning needed to be uttered against the over-frequent employment of the operation; there was a risk of abuse in this direction, and nothing was more calculated to damage its utility and good name. As long as our present skill in diagnosing the exact condition of the organs within the pelvis was so imperfect, hindrances would always exist in judging the correct indications for the operation; in all cases the importance of a careful course of medical treatment must be weighed before radical measures were adopted with the knife, and the physician's skill must be exhausted before the appendages are removed. Brief reference was made to the other papers promised, especially those by Dr. Lusk and Dr. Emmet, and a hope expressed that many points would be brought out in the discussion following. In conclusion, Dr. Meadows, after referring once more with pride to the advances made, dwelt for a short time on what might be called the dark spots in gynecology, and trusted light might soon be thrown even on these. It was most desirable that we should possess an exact knowledge of the effects of drugs on the various pelvic organs; a great step would have been made when we ascertained the action of one or two drugs on each of these structures; if the action of even one remedy was clearly defined at this meeting, the labors of the Section would not have been in vain.

DR. ROBERT BARNES read a paper on

THE ALTERNATIVE TO CRANIOTOMY.

The author at the outset laid it down as a rule that the nearer we attain to the abolition of craniotomy the nearer do we attain to perfection. After drawing attention to a memoir which had been written by Dr. Tyler Smith in condemnation of the operation, it was pointed out that craniotomy was almost always performed for some condition of pelvic distortion, and as the latter was to a great extent a preventable disease, we could hope for considerable assistance in the abolition of the operation from measures which improved the sanitary surroundings of our young girls. Here was a domain in which medicine and hygiene had their scope. As a matter of fact, the passing of the Factory Act, which limited the age at which young girls could be employed in the workshop, had done much to lessen the frequency of pelvic distortion. The testimony of medical men in our large manufacturing towns showed that pelvic deformations were much less common than they were fifty years ago; while in countries such as Germany, where no such safeguards were adopted, the museums were full of specimens of distorted pelves, and craniotomy was of frequent occurrence. Craniotomy had been done in two classes of cases: (1) those in which the head was delayed above the brim, and in which the perforator was justly used; and (2) cases in which the head was delayed in the pelvic cavity, and in which forceps ought to be employed. In the first class there could be no question that premature labor ought to be induced: even if the head was then large, the vertex was very plastic and could be readily moulded; or, in more extreme cases, turning could be practised. When once a fœtus was known to be dead, it was not necessary to seek any alternative to craniotomy. If the pelvis was known to be impassable, should abortion be done at an early month, or should the woman be allowed to go full time with the prospect of Cæsarean section? The former seemed preferable. If the child has gone full time, then some alternative must be sought. In considering embryotomy, it must be borne in mind that the instruments for the operation had been greatly improved. The advantages of Porro's operation was that the child was saved, and

the mother, too, probably; in the Cæsarean section the mother is liable to be exposed to the same danger again and again; if craniotomy is tried and fails, the result of Porro's operation or Cæsarean section is rendered less hopeful. In contracted pelves, where the diameter is three and a half to three inches, the mortality after craniotomy ought to be no greater than in normal delivery; here Cæsarean section or Porro's operation are not indicated, nor are they justifiable. Religion and sentiment had both exercised an influence on the performance of embryotomy, but the subject should be weighed quite apart from these factors, and the teaching of science alone be regarded. One question we had to consider was this: "Is Cæsarean section, even with its modern improvement, as good and safe for the mother as embryotomy?" In the case of Porro's operation there would always be the existence of shock to the mother, due to the strangling of the neck of the uterus by the serre-nœud; this must always be a serious matter for consideration. In the hands of men skilled in abdominal surgery Dr. Barnes felt sure both Cæsarean section and Porro's operation would give brilliant results; but the case of the general practitioner had to be considered, and was there not a great risk of a vastly increased mortality if the latter, with only a few and distant opportunities for operating, was to substitute abdominal section, as a rule, for the easier operation of craniotomy. Cases often occurred in which moderate degrees of contracted pelvis was not diagnosed till the first labor; in such instances it was justifiable to perform embryotomy, since in succeeding pregnancies living children could be born by the induction of premature labor, and thus lives saved. In extreme cases of pelvic distortion, where the opportunity for the induction of labor had been passed by, Porro's operation ought to be done. In pelves with a diameter of three and a half to three and a quarter inches craniotomy was indicated; in cases complicated by tumor, in ruptures of the uterus, and disease of the latter organ, Porro's operation was called for; in atresia of the cervix Cæsarean section might be needed; in convulsions or in hemorrhage labor should be brought on and craniotomy avoided. In conclusion, the writer remarked that the best alternative to embryotomy lay in the production of a perfectly healthy and virtuous female population.

Dr. Kinkead, of Galway, read a paper on

CRANIOTOMY AND CÆSAREAN SECTION.

He admitted that under certain favorable conditions Porro's operation was desirable, but was inclined to give the preference to Cæsarean section. The causes of death after the latter proceeding were—1, shock and exhaustion; 2, peritonitis; 3, incarceration of intestine; and 4, hemorrhage. Craniotomy with a pelvis of only one and a half inch in diameter was to be condemned; it often had to be followed by Cæsarean section or Porro's operation. As regards the occurrence of shock, there was no greater risk in this respect after Cæsarean section than there was after craniotomy. Hemorrhage during the former operation could always be restrained by compression of the cervix, either with the fingers or by an elastic band; in late hemorrhage this method was of course not available. Careful and close suture of the edges of the uterine incision was the only real safeguard against late bleeding. The employment of a mere continued suture had been shown to be useless; the right way was to make peritoneal flaps and treat the incision by Sainger's method. Dr. Kinkead approved of the use of carbolized gut for sutures. Great stress must be laid on the careful sponging out of the peritoneal cavity after the operation; the toilet of the peritoneum required to be made as carefully as after the performance of ovariotomy, if success was to be assured. Cæsarean section ought to be as safe for the mother as craniotomy. The performance of craniotomy through a conjugate diameter of two and a half inches was dangerous and hard, while Cæsarean section presented no difficulties to any man.

Dr. W. T. Lusk, of New York, remarked that as in England, so in America, cases of extreme pelvic distortion were rare. Below a three-inch diameter craniotomy was always a serious operation, and, looking back to his own experience, he often felt regret at the thought of some cases he had done embryotomy on in the earlier years of his practice. Certainly the result of his observation was to make him hope that before long craniotomy would be abolished. Men had spoken of the bad success attendant on Cæsarean section, and referred to the almost constant failures at the large lying-in hospitals of Vienna and elsewhere; but in making such quotations we must remember what a mortality normal labors had formerly at these centres, and then we should cease to wonder at the failure of the Cæsarean section. Moreover, looking over the statistics of Michaelis, for example, we found that many cases were operated on when in *articulo mortis*, and then recorded as failures due to the operation. Reference was made to cases of Cæsarean section done lately by Leopold, according to Sainger's method, and in these the success had been most encouraging. If the pelvic diameter was under two and a half inches the Cæsarean section gave better results than craniotomy. In his opinion Porro's operation should be reserved for cases in which labor had been prolonged and degenerative changes had taken place in the uterine tissue; in cases where the uterus had undergone marked retraction and the vagina had been dragged up, Dr. Thomas' operation of laparoelytrotomy was indicated. The latter operation had scarcely had a fair trial; in cases where the general conditions were good it would be found decidedly successful.

Dr. Wilson, of Baltimore, strongly confirmed all that the previous speaker had said, and spoke in strong condemnation of craniotomy.

Dr. Swayne thought embryotomy could never be abolished; in certain cases the operation was perfectly justifiable, though at times turning might be more advantageously employed. Where the conjugate diameter was below three inches he would abolish craniotomy and perform a Porro operation.

Mr. Lawson Tait protested against the idea that Cæsarean section was necessarily a fatal operation. As regards craniotomy, however, there was a political side to the question, and the matter might be regarded from the standpoint of political economy; over-population was one of the great difficulties of the present day, and a certain amount of infant mortality in childbirth was not without its advantages. The question might be viewed from the side of morality, and certainly we had no right to destroy life. Much harm, however, had been done by regarding woman exclusively as a childbearing machine, and against such a view he would energetically protest. In his opinion Porro's operation would give better results than craniotomy, even in the hands of an inexperienced operator.

Dr. Moore Madden considered that craniotomy could not be too strongly condemned. In an experience of twenty years, with large opportunities for obstetric experience, he had never once seen a case in which he could think craniotomy was called for. He wished to press strongly the question, "Are we justified in destroying any life?" The child was in utero through no fault of its own, and its life was as precious as that of the mother; the idea of over-population, as suggested by the last speaker, could not be weighed in the argument for a moment. The operation of craniotomy was a disgrace to us; the best reference to it was given in the dictum of Sir James Simpson, viz.: "Cold steel for the child and mercury for the mother." He looked forward to the time when craniotomy would be a thing of the past.

Dr. Neville could scarcely believe that cases requiring craniotomy or Cæsarean section were so rare as Dr. Madden seemed to suggest. In his opinion Cæsarean

section was the preferable operation; Sänger's modification of the Cæsarean section had [illegible] cases with only 7 deaths, and would probably [illegible] improvement even on these figures.

Dr. Buchanan, of Glasgow, thought that the opinions of a surgeon in matters relating to obstetrics was valueless. Doubtless craniotomy was far too frequently done. It had been said, "Given a case of deformity at the brim—if an obstetrician attends, we see craniotomy; if a midwife, a living child;" and there was some truth in the old adage. Personally he had done craniotomy with success where the pelvic diameter was only one and three-quarters of an inch; but in such cases the patient must be seen early, before the liquor amnii has long escaped. In withdrawing pieces of bone great care was needed lest soft structures should be damaged; very often the fatal results of craniotomy were due to want of care in the above respect. Say what we may, Cæsarean section was a fatal operation; in Glasgow there had not been a single successful case; he should prefer Porro's operation to Cæsarean section.

Dr. Thompson denounced craniotomy in the severest terms, and expressed strong opinions in favor of Porro's operation and the Cæsarean section; to his mind men had been backward in performing these latter to the extent they deserved.

Dr. James, in an experience of forty years of extensive private practice, had never once seen a case in which craniotomy was indicated. He advocated an early use of the forceps, and had gained great benefit from the practice.

Dr. Edis thought that the subject of preventive midwifery had hardly received the notice it deserved. In every case a preliminary examination ought to be made when we first see our patient, so that time may exist for the induction of premature labor, if pelvic deformity is found to be present. In every case in which craniotomy has once been performed the patient should be solemnly warned of her condition, and the exact condition explained to her. The difficulties in connection with the operation of laparo-elytrotomy were insisted upon, and Dr. Edis expressed the opinion that the large surgical procedures in obstetrics must always rest in the hands of men with special surgical experience and skill.

Dr. Wright spoke earnestly in favor of Porro's operation, and expressed a firm belief in its advantages.

Dr. Robert Barnes, in reply, stated that the progress of Cæsarean section would depend on the progress of surgical skill, and on judgment in the election of cases. In cases where the pelvic diameter was between three and a half and three inches craniotomy would give as good results as normal labor. He cordially approved of Dr. Edis' remarks. It was a matter of regret that in the discussion speakers had not made more distinction between cases of moderate and cases of extreme pelvic distortion; the latter cases ought to be put in a separate catalogue by themselves. In Porro's operation shock due to the strangling of the neck of the womb would always be an important factor, and for that reason Sänger's modified Cæsarean section had a distinct advantage.

Dr. T. A. Emmet, of New York, read a paper on

CERTAIN MOOTED POINTS IN GYNECOLOGY.

In commencing his subject, Dr. Emmet warned his hearers not to lay too much stress on versions and flexions of the uterus as causes of various symptoms arising apparently from the pelvic organs. Dysmenorrhœa, uterine fluxions, and discharges might be only one way in which the uterus obtained relief for itself; the really important point was to weigh the coincidence of pelvic inflammation, peritonic or cellulitic. A pessary was of little use in merely altering the direction of the uterine axis; if it corrected a prolapsus, it was doing real service, but not else. In using a pessary one always had to consider the risk that the instrument might cause dragging on a tissue already inflamed, and increase the latter. One effect of uterine displacement was to cause stretching of the neighboring blood-vessels and tension of the pelvic fascia—conditions which easily led on to inflammation; by lifting up the uterus, and removing the sources of mischief, a pessary did good and helped to restore the circulation to its normal condition. As regards the forms of displacement, it must be noted that retroversion was often congenital, and in itself of no importance. Dysmenorrhœa was never due to uterine flexions, the association was merely accidental; the fault really lay in the nervous system, and not in the obstruction. It must always be remembered that dysmenorrhœa was only a symptom. Dr. Emmet considered that forcible dilatation for dysmenorrhœa was to be condemned as unscientific, for the cervix may be patulous and yet dysmenorrhœa exist; in most cases of painful menstruation pelvic peritonitis was present and existed as a cause. Referring to the effects of fissure of the cervix, the author was convinced that one point had been brought clearly and certainly home to his mind, namely, that epithelioma of the cervix was commonly secondary to, and the direct result of, a previous fissuring of the neck of the womb. Now and then pregnancy might cause the removal of the effects of pelvic peritonitis, but it could not be surely relied on; dilatation, by causing pregnancy to become possible, was sometimes of use in this way. Numerous cases of pelvic peritonitis and troublesome adhesions had been caused by the injudicious use of ergot; with an undilated "os," and the presence of a fibroid in the uterine cavity, ergot only increased the congestion of the pelvis. Hot-water injections into the vagina lessened pelvic congestion, and we possessed no better method of relieving dysmenorrhœa than by the employment of the hot vaginal douche. This latter fact would not be the case if painful menstruation depended, as some suppose, on mechanical obstruction. Endometritis and endocervicitis were rare, except in theory; the real trouble consisted of a surrounding pelvic peritonitis; once this latter was checked, and the circulation thus restored, all uterine discharges would cease. As regards the application of iodine to the interior of the womb, the author stated that he rarely employs this treatment; as a matter of fact he had reached a point in practice in which he seldom introduced an instrument into the uterus—his uterine sound had been broken for eighteen months, and he had never missed it. All that a sound taught might be made out with the fingers. The uterine mucous membrane would so readily absorb all substances presented to it that it was advisable to do all that was possible by way of the vaginal mucous membrane; moreover, the latter had the advantage of presenting a more extensive surface. By giving up applications to the interior of the uterus, and by largely discarding the use of pessaries, Dr. Emmet had increased his success in treatment; the use of glycerine pledgets he always found valuable. Pelvic peritonitis must always be more common than cellulitis; in chronic cases of the latter disease the connective tissue seemed to become absorbed and disappear, till finally the appearances presented were those of pelvic peritonitis.

Dr. Graily Hewitt read a paper entitled

THE EARLY HISTORY AND ETIOLOGY OF UTERINE FLEXIONS AND DISPLACEMENTS.

In opening the discussion, Dr. Hewitt dwelt briefly on the congenital displacements of the uterus; it must be clear that the normal forward inclination of the uterus must favor anterior displacements. The condition of congenital retroflexion was undoubtedly much rarer than the corresponding anterior malformation, yet it did undoubtedly exist; retroflexion was not uncommonly found in virgins—reference to his case books showed that out of 250 cases 60 occurred in young virgins. Probably an abnormally loose condition of the utero-sacral ligaments was one cause of congenital backward displacements. In considering the pathological production of flexions it

was very important to weigh the state of the uterine tissue; undue softness of the wall of the womb is not infrequently met with, and if associated, as it often is, with abnormal thinness of the muscular parietes, flexibility is increased and the condition of flexion favored. Dr. Emmet's view, that impaired nutrition of the uterus, due to congestion of the pelvic viscera, acted as a cause, was also true, and malnutrition of the uterine muscle was often the first step in the chain of processes which ended in the establishment of a flexion. The changes undergone by the uterus at puberty without doubt exerted a powerful influence on the after-shape of the uterus; this was well illustrated by cases of imperfect development of that organ. Most cases seen in practice were caused by an acquired softness of tissue; the part played by subinvolution was doubtful. In many cases of flexions undue hardness of the uterine tissue existed; this was really secondary to pre-existing softness, and depended on long-standing congestion with overgrowth of connective tissue; it acted perniciously by fixing the flexions, just as plaster-of-Paris sets a mould when it gradually hardens. The action of traumatism was most important as a cause of flexion; lifting, retching, straining, and muscular effort, all tended to produce uterine displacement, and once the uterus has slightly prolapsed the case is likely to go on from bad to worse. Among the examples of acute traumatism must be reckoned blows, falls, jerks, etc.; of course, granted one finds a flexion and there is a history of violence, it does not necessarily result that the two are connected; but when, after a fall or jerk, the next menstrual period is abnormal, and vaginal examination shows the existence of a flexion, it is fair to connect the two. Numerous cases of displacement, due apparently to the various causes enumerated, were given by the author by way of illustration. Once produced there was no difference in the way in which anteflexion and retroflexion became intensified.

In the discussion that followed the reading of the papers by Dr. Emmet and Dr. Graily Hewitt, Dr. Bantoch remarked that he was obliged to entirely disagree with Dr. Emmet. With regard to the pathology of pelvic inflammation he would say nothing, but on the subject of pessaries he must speak strongly. He could not lay too great stress on the value of a well-adjusted pessary. Patients suffering with severe headache, and hardly able to walk, were at once relieved by the application of a well-fitting instrument; the relief given was so immediate that it could not be due to an improved condition of the pelvic circulation. Dr. Emmet had spoken of dysmenorrhœa as a single disease, while really it depended on many causes, *e.g.*, on the state of the ovaries, of the tubes, displacements, etc. Dr. Bantoch considered that division of the cervix alone would cure a mechanical dysmenorrhœa, and cited a case in illustration. Perfect rest might be a substitute for internal remedies applied to the uterine canal, but many patients could not afford to lie up for twelve months.

Dr. Gordon, while agreeing in the main with Dr. Emmet, yet thought that dilatation was occasionally of use, and regarded it as a form of nerve-stretching. The idea that chronic inflammation attacked the uterus was utterly fallacious; there was no such form of disease, and the theory had done immense harm. What really did exist was a *chronic passive congestion*—a process usually secondary to an *acute* but brief attack of inflammation. Pessaries could not be slighted, for they served to maintain the uterus in a favorable condition for processes of repair. There was no need to defer operation in cases of lacerated cervix, for the operation itself did good by depleting the part and relieving congestion.

Dr. A. B. Hirsh has been elected Adjunct Professor of Orthopædic Surgery in the Philadelphia Polyclinic, and also Orthopædic Surgeon to the United Hebrew Charities of Philadelphia.

SECTION IN SURGERY.

Friday, August 13th—Fourth Day.

The President of the Section took the chair at eleven o'clock.

Professor Victor Horsley, M.B., F.R.S., then read a paper on

THE ADVANCES IN THE SURGERY OF THE CENTRAL NERVOUS SYSTEM.

Professor Horsley related the history of several cases in which cerebral operations had been performed. His paper was illustrated by photographs illuminated by the lime-light, and some living patients were shown at its close.

A short discussion on the subject then took place

Professor Charcot, of Paris, referred to the labors of Fournier and Hughlings Jackson in cerebral localization.

Dr. Hughlings Jackson followed and related some cases he had observed. In one case, under the care of Sir Andrew Clark, at the London Hospital, the patient had ninety-six convulsive attacks in all, every one of which began in the thumb. By experimenting on a monkey it was found that similar convulsions could be caused, and the probable centre affected in man was thus ascertained.

Dr. Royle, of Manchester, also spoke.

Mr. Bruce Clarke then read a paper on

THE EMPLOYMENT OF ELECTRICITY IN THE TREATMENT OF DISEASES OF THE URINARY ORGANS.

He thought Stohrer's battery the best for the purpose. The use of a galvanometer was necessary, for the employment of a given number of cells was no guarantee of the strength of the current, as the latter lessened during the operation. The exact strength of the current and the length of time during which it should be passed were matters for consideration in each individual case. Electricity was often of use in cases of incontinence and stricture, where the former was of long standing, and where the passage of a catheter showed a tender spot to be present in the urethra. In such cases the passage of a metal electrode down the urethra, and the passage of an electric current through it for a few minutes, on reaching the tender spot, often gave relief. The positive pole was applied to the sacrum, and the negative one in the urethra. Mr. Bruce Clarke described a case in which the patient had had six attacks of gonorrhœa, and was suffering from gonorrhœal rheumatism. A bougie electrode (No. 9 English) was passed down the urethra and passed to and fro for six minutes while the current was passed. There was no pain at the time of the operation, but slight pain in the testicles next day. The pain in the knee joints went away, and the patient was soon able to walk. In the treatment of incontinence, from two and a half to five *milliampères* was a sufficient strength of current. The negative pole was placed either on the perineum, or in the bladder, or over the pubes. Mr. Clarke also alluded to electricity as an agent of use in treating cystitis. For its use in the treatment of stricture he referred to a paper read by Dr. Steavenson and himself before the Medico-Chirurgical Society some months ago.

Dr. Steavenson then read a paper on the same subject, in which he discussed more especially

THE TREATMENT OF URETHRAL STRICTURE BY ELECTRICITY.

Electrolysis, he said, did not burn as did the cautery. He supposed that what really occurred was that a series of decompositions and recompositions occurred as the current passed from one to the other pole of the battery. He referred to the recent lectures of Dr. Stone before the Royal College of Physicians. The cathode was safer to employ than the anode for application to places where it was desirable to leave no scar. The electrolytic treatment of stricture possessed several advantages. No

anæsthetic was necessary, and it was a great assistance to the operator for the patient to be conscious. No bleeding need occur. If any did take place it showed either that the current was too strong or that the wrong pole had been used. Antiseptics were not needed, as the process was aseptic. The negative pole set up destruction of tissue similar to that caused by the caustic alkalies, but an absorptive action around the stricture was also started as the capacity of the urethra went on increasing after the operation. In the majority of cases no recontraction occurred. Dr. Steavenson concluded by reiterating that electrolysis was not the same as the galvano-cautery, and did not leave a scar.

Mr. Erichsen said that Mr. Bruce Clarke's cases were different. In using electricity for the treatment of incontinence an action on the nervous centres took place. In using it for cystitis it must not be forgotten that catheterization was practised, and part of the benefit might be due to that. Electrolysis as a remedy for stricture was not altogether new, for he remembered a French gentleman coming to University College Hospital, twenty years ago, and giving a demonstration on the subject. The decomposition of tissue caused by electrolysis was analogous to that set up by the application of potassa fusa. Cases treated by the latter agent, however, frequently did badly ultimately.

Mr. Vincent Jackson, of Wolverhampton, asked as to the after-treatment. Another gentleman asked as to the use of electricity to the external parts of the body.

Mr. Bruce Clarke then replied. He agreed, he said, with Mr. Erichsen, that his cases were very dissimilar, and he could not explain how the same agent (electricity) could do equal good to cases varying so much from one another. He felt they were only upon the threshold of the subject. Electricity might, perhaps, improve the nutrition of the parts to which it was applied. In reply to Mr. Vincent Jackson he said he should shortly publish a series of cases and give full details. He would, however, mention one case. This was that of a patient whose stricture had been incised nine months before he had seen him. Relapse had occurred and the stricture would only just admit a catheter. After six weeks' electric treatment the patient was discharged well, and a No. 11 could be passed. This favorable result was achieved in spite of the perineal fistula re-forming—a result which might, he admitted, be due to the passage of the current. He saw the patient three weeks ago and the improvement was maintained. As to the application of the electrolytic current to external parts of the body, he had used it thus: One case was one of stricture at the meatus, and he watched the process. Another was that of a strumous scar in the neck. In both cases no destruction of epithelium took place, but the tissues seemed simply to melt away after four or five applications. No soreness was caused. In the case of the scar in the neck, a marked diminution in its size rapidly occurred, as shown by a comparison of the scar from time to time with a plaster cast which had been taken of it before the operation.

Dr. Steavenson also replied. He said that in stricture a process of electrolysis occurred, but suggested that when electricity was used for the treatment of cystitis and incontinence it acted upon the nerve-centres in the cord and strengthened their inhibitory action. When the negative pole was used for application to the tissues no decomposition of the metal pole occurred (this did occur if the positive pole were used), but an action similar to that caused by the application of caustic potash. You could, however, limit the action and remove the electrode as soon as a sufficient application had been made. This could not be done in using caustic potash. Mr. Bruce Clarke and himself, he said, had been led to take up the subject by the American literature on the subject. Dr. Newman, of New York, had had a hundred cases (and some of them were now of eleven years' standing) in which no recontraction had taken place.

Mr. Reginald Harrison, of Liverpool, then read a paper on

THE TREATMENT OF PERINEAL TRICK FISTULÆ BY INTERNAL AND EXTERNAL URETHROTOMY COMBINED.

Mr. Harrison said he had known no case in which urethrotomy had been followed by a stricture. Where rupture of the urethra had occurred, if the urethra were excised and the wound treated as a lithotomy wound, a traumatic stricture did not necessarily result. It was almost invariable for urinary fever to occur after urethrotomy. But this was not so after lithotomy. He thought it had something to do with the urine, and referred to M. Bouchard's views on

TOXIC URINE,

which he had recently discussed at length in the *Liverpool Medical Journal*. Mr. Harrison said he had determined—after performing internal urethrotomy—to open the membranous urethra, and pass a catheter thence into the bladder, so that no urine passed over the wound caused by the internal urethrotomy. During the last two and a half years he had now adopted this procedure in twenty cases. All were selected cases, in which there was great contraction. No rigor followed the operation in any case, and in most of them no contraction occurred. In every one of the twenty cases the healing of the perineal opening was perfect. Mr. Harrison said his method was no novelty, for Professor Annandale, of Edinburgh, practised it in 1875. Otis also wrote advocating the same combined method for strictures deeper than five and a half inches.

Professor Pancoast showed a silver bougie-catheter devised for the purpose of keeping the urine from the wound.

Dr. Ward Cousins and Mr. Walter Whitehead also spoke.

Mr. Reginald Harrison then replied, and said it was a question of perfect drainage.

WHERE DRAINAGE WAS PERFECT THERE WAS NO UREthral FEVER.

The meeting then adjourned for an hour for luncheon.

On resuming the work of the Section, at 2 P.M., Mr. Noble Smith read a paper entitled

ON OBSCURE DISEASE OF THE SPINAL COLUMN.

Spinal cases were sometimes very obscure, he said, and pain might be absent. Caries of the spine was nearly always the effect of scrofula, and rest for the diseased part was necessary, or the patient would get worse and die. Surgeons differed as to the method of applying it. He believed plaster-of-Paris might be used more freely if applied on a different method. He objected to pressure being made on the side of the thorax. Mr. Noble Smith advocated the use of an apparatus applied to the back only and leaving the chest free.

Mr. Jessop, of Leeds, having made a few remarks, Sir William Stokes, of Dublin, then read a paper on

ACUTE MYXŒDEMA FOLLOWING THYROIDECTOMY.

The case was that of a young girl with enlarged thyroid. There was not only considerable deformity, but urgent dyspnœa to such an extent as to lead them to think tracheotomy might be required. He operated on the lines laid down by Kocher, and the operation was difficult. Considerable hemorrhage occurred, although the vessels were secured as far as possible before being divided. The operation was performed antiseptically, and the wound afterward dressed with sublimate gauze. Only the left lobe of the thyroid was removed. After the operation the right lobe lessened, but this decrease in size was not permanent. It again enlarged and caused so much dyspnœa that a second operation for the removal of the right lobe was attempted. The second operation was also difficult, and occupied an hour and a half. The vessels were very friable. The patient was

much collapsed, and hypodermatic injections of ether were made and brandy given internally. Milk and beef-tea were afterward given. The tumor removed weighed seventeen ounces. On the second day fair reaction occurred. All was satisfactory until the eleventh day. The pulse, temperature, and respirations were normal; the wound aseptic, and union firm. On the eleventh day the patient was sitting up and seemed well. On the twelfth day the patient was still going on well, so far as regarded her pulse, respirations, and temperature, but she complained of a dull aching pain in her legs and knee-joints. Then an epileptiform convulsive seizure came on. Subsequently slight puffy swelling of the hands and feet was noticed, and also some mental torpidity. These symptoms increased up to the twenty-first day. The convulsive seizures occurred again and again, and each one left the patient weaker and with greater pulmonary oppression. Two days later she died. At the autopsy the lungs were found highly œdematous and the epithelium was desquamating.

Mr. Erichsen referred to the history of the subject and suggested that

ONLY DIVISION OF THE ISTHMUS SHOULD BE PRACTISED.

Had anyone, he asked, seen a case in which the isthmus had been divided causing atrophy of one lobe without any further result?

Mr. Lennox Browne then read a paper on

THE MORE COMPLETE SURGICAL TREATMENT OF SUFFOCATIVE GOITRE.

He said the distinction between fibrous and cystic goitre was not maintainable. It was to Sir Duncan Gibb that we were indebted for the suggestion to divide the isthmus. He remarked that menorrhagia was a frequent complication of thyroid tumors, though, in young girls, amenorrhœa occasionally occurred.

Mr. Hemming asked whether any part of the isthmus should be removed? He had seen one case in which a part of the isthmus had been removed, and another in which simple division had been practised.

Mr. Jessop referred to a case in which he thought the central lobe produced pressure.

Mr. Lennox Browne said he had removed a portion of the isthmus in one case. His impression was that the central lobe produced pressure rarely.

Mr. Walter Whitehead then read a paper on

THREE HUNDRED CONSECUTIVE CASES OF HÆMORRHOIDS CURED BY EXCISION.

He had, he said, abandoned the ligature, as he found that the disease recurred. After abandoning the ligature he had tried the cautery in over fifty cases, with a resulting conviction that it was inferior to the ligature. He had never used it since 1876. Then he had adopted excision and used it in every case, with the exception of a few in which he had employed galvano-puncture. He had had no death, no secondary hemorrhage, no complications, and, to the best of his knowledge, all his patients were safely and permanently cured. He observed that no surgeon understood the anatomy of hæmorrhoids until he had removed them from living patients. They were not distinct tumors, but a plexus of veins surrounding the gut was invariably involved. He preferred the lithotomy position. Instrumental dilatation of the sphincter was objectionable. The incisions should be made through mucous membrane, and not through the skin.

Professor Pancoast and Mr. Jessop then made a few remarks, the latter being in favor of the cautery. Mr. Reeves also joined in the discussion.

Mr. Erichsen remarking that

CONTRADICTION SOMETIMES FOLLOWED THE USE OF THE CLAMP AND CAUTERY,

asked whether such was the case after the galvano-cautery?

Mr. Whitehead replied, and said that on an average his patients were able to resume business in ten days.

Mr. Charles Smith, of Brighton, then showed and explained his

NEW CLAMP FOR THE TREATMENT OF HÆMORRHOIDS

in place of reading the paper on the same which had been announced by him. It was, he said, on the model of the "spanner," as would doubtless be observed by those of a mechanical turn of mind. He remarked that ether was an objectionable anæsthetic in rectal cases, as it caused congestion of the rectum.

Mr. Benton then read a paper on

FISTULA IN ANO OF THE HORSE-SHOE SHAPE.

It was, he said, very rare, and he had only met with five instances among seven hundred and fifty cases of rectal disease.

Mr. Startin read a paper on

THE SURGICAL TREATMENT OF ACNE AND LUPUS.

He had used electrolysis in treating the latter, and exhibited the needle he employed for the purpose. He used a Grove's battery of twenty cells.

Dr. Wile, of Newtown, Conn., then read a paper

ON THE RELATION WHICH ALIMENTATION BEARS TO THE RESULTS OF SURGICAL PRACTICE.

He had, he said, failed to find any treatise on diet in surgical practice in libraries containing fifty thousand volumes of medical works. There were works on diet, and special works on invalid diet, and diet for infants, but none on diet for surgical patients, nor had he been able to find even an article on the subject. In surgical cases he urged that those substances should be given as food which yielded the largest amount of albumen to the blood. The processes of repair in a part only went on when it was abundantly supplied with albuminous bodies. It was necessary that an adequate supply of these should be supplied to the blood in such a form as could be easily digested. Suitable aliments were milk—either simple, or pancreatized by the addition of pancreatic extract and bicarbonate of soda—eggs, slightly cooked, and meat, either cooked or, in some cases, given raw.

Papers by Mr. F. Churchill ("On the Multiple Causation and the Immediate Treatment of Congenital Club-foot") and by Mr. F. B. Jesset ("Surgical Treatment of Certain Tumors of the Neck") were then read. The latter advocated early interference with cervical tumors, and said they should not be allowed to grow to a large size unchecked.

The proceedings of the Section then terminated.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

Tenth Annual Session, held at Indian Harbor Hotel, Greenwich, Conn., August 25, 26, and 27, 1886.

(Continued from page 275.)

Wednesday, August 25th—First Day—Morning Session.

In the absence of the author, Dr. G. H. Fox, of New York, a paper was read by the Secretary, entitled

REPORT OF A CASE OF LYMPHADENOMA (MYCOSIS FUNGOIDE) AND AUTOPSY.

The paper described the case of Mrs. G——, thirty-three years of age, the mother of six children. During pregnancy, in 1881, she suffered with general pruritis, which passed away after confinement in October. A year later, small, flattened, circular tumors appeared in the axillæ and on the breasts. These became moist, and were accompanied with a burning sensation. The eruption disappeared from these situations and reappeared upon the back and other portions of the body. After the birth of her last child, in February, 1885, a tumor developed at the inferior angle of the left scapula. The lesions on the other parts of the body disappeared, with the exception of two spots on the finger and one on the left

cheek. The tumor on the left scapula gradually softened and disappeared.

The patient was admitted to the hospital in October, 1885, and was fairly well nourished. There were at this time numerous tumors over the body, some of which were superficially ulcerated. The worst tumors were on the breast. Hypodermatic injections of Fowler's solution were used without benefit. Chaulmoogra oil was given in increasing doses without causing any improvement.

The patient died in April, 1886. The microscopical examination gave the usual appearances of these growths. The internal organs were found to be normal.

A NOTE RELATIVE TO THE BULLOUS ERUPTION OCCURRING AFTER THE INGESTION OF IODINE COMPOUNDS.

A paper with this title was, in the absence of the author, Dr. J. N. Hyde, of Chicago, read by the Secretary.

The first case described was that of an infant, aged seven months. Three weeks before coming under observation the eruption made its appearance. The face, the dorsal aspect of the hands and forearms, and the scalp were covered with isolated whitish, split-pea to marble-sized, flattened, slightly umbilicated lesions resembling molluscous tumors. The contents of the lesions were inspissated, thick, and grumous. It was learned that iodide of potassium in one-grain doses had been administered for a febrile attack. On the discontinuance of the iodide and the use of antiseptic powder the lesions rapidly disappeared.

Case II.—A lad, fifteen years of age, who had recently undergone an operation for necrosis of the right femur, developed an eruption involving the entire body. There were two distinct sets of lesions. That which predominated was composed of annular circinate plaques, varying in diameter from several centimetres to half a metre. There were also here and there, particularly about the finger-ends, distinct blebs. The patient had been taking iodide of potassium in fifteen-grain doses. This was discontinued and the eruption speedily disappeared.

The speaker then referred to other cases of similar eruptions described by various writers, and in conclusion presented the following interrogative propositions :

1. Are there not three sub-forms of the bullous exanthem developed in certain individuals after the ingestion of iodide of potassium ?

2. Is not the first and most common of these to be generally recognized in persons of advanced age and cachectic condition, the rash being then present in the form of typical bullæ ?

3. Is there a second and still rarer sub-form, in which the eruption is displayed in di- or polymorphic manifestations, typical, perfect bullæ being then mingled with papules, tubercles, scarlatiniform maculations, or with other and different lesions ?

4. Is there not a third and rarer sub-form, the quasi-bullous rash to be most frequently recognized on the face and dorsal aspect of the hands and forearms of infants and children, where the lesions are semi-solid, slightly umbilicated, and filled with inspissated, yellowish matter, and which may shrivel and dessicate on the suspension of the drug inducing the condition ?

5. Is this last-described lesion one to be recognized solely as the result of the ingestion of iodide of potassium, never under other circumstances, and one as peculiar to the special condition it represents as is the gumma to syphilis ?

Adjourned until evening.

Evening Session.

Dr. R. W. Taylor, of New York, read the first paper, which was entitled

PRECOCIOUS GUMMATA.

The following conclusions were presented :

1. Like the osseous affections, affections of the nervous system, malignant syphilides in general, besides many other affections, the gummata syphilæ may be precocious in appearance, occurring as early even as the second month of infection, but usually in the third or fourth month, or after that time.

2. Of the precocious gummatous syphilide or gummata there are three quite clearly marked forms : First, the early, general, and copious form ; second, the more localized form, which may invade several regions, is usually symmetrically distributed, and sometimes even is confined to one region, particularly one side of the face or scalp, and the roof of the mouth ; and third, a form in which more or less severe neuralgias precede and accompany the eruption, which in many particulars resembles simple erythema nodosum, but which in its etiology is not in any way related to this simple form of eruption, but is a direct outcome of the syphilitic diathesis.

3. That these precocious gummata partake in general of the features of those of later forms, but that they differ in a more acute invasion, in a much more rapid course, and are usually not as profound and destructive in their action as the classical eruption.

4. That of these precocious forms of gummata, there are found to be two varieties : one a non-ulcerative or resolutive, the other ulcerative.

5. That in the treatment of these precocious syphilides, a combination of mercury and iodide of potassium is much more efficacious than is mercury alone.

CLINICAL NOTES ON SCABIES.

The speaker, Dr. F. B. Greenough, of Boston, had noted a rapid increase in the number of cases of scabies seen during the past few years. The number of cases had rapidly increased from three in 1879 to one hundred and sixty during the last year. Inquiries as to the number of members of the same family of whom the patients could give an account as being similarly affected gave one hundred and ten such cases, which, with six cases seen in private practice and the one hundred and sixty above reported, made a total of two hundred and seventy-six cases that had come under his cognizance during the past year. The percentage of cases of scabies to other cases of skin disease had varied from three-tenths per cent. in 1876 to over thirteen per cent. during the past year. This great increase in frequency seemed to be one of the most interesting and important points brought out by his notes.

The facts which were especially noticed were, the few cases in which typical burrows could be found ; the great constancy of the manifestations on the penis in male subjects ; the difference of the symptoms produced by scratching, according to the situation of the lesion ; and the success of treatment. He had used almost entirely an ointment consisting of two parts of sulphur, one of carbonate of potash, and three of petroleum ointment, simply cautioning the patient against applying it to inflamed and pustular localities. He referred to the distribution of the eruption as of importance in the diagnosis of difficult cases, and called attention to the differential diagnosis between scabies and certain other cutaneous diseases.

DISCUSSION.

Dr. A. R. Robinson, of New York, suggested that in cases where there was difficulty in the diagnosis, a vesicle be opened and its contents examined under the microscope, for the young acari or the fæces.

Dr. L. N. Denslow, of St. Paul, had seen a number of cases in which no burrows could be found, but under treatment suitable for scabies they have recovered. The treatment used has been thorough scrubbing from head to foot, followed by the application of sulphur ointment.

Dr. E. B. Bronson, of New York, agreed with the author of the paper as to the frequent absence of the cuniculi. In many cases he had depended largely upon the elongated character of the efflorescence in making the diagnosis. For three months, he treated all cases of scabies with naphthol, using a fifty per cent. preparatio

rubbing the body thoroughly with this once. This has produced a satisfactory result.

Dr. S. Sherwell, of Brooklyn, recommended as a prophylactic the sprinkling on the sheet of a teaspoonful of the dry sulphur. This acts as a disinfectant and is unpleasant to the acarus.

Dr. H. W. Stelwagon, of Philadelphia, presented some

CLINICAL OBSERVATIONS REGARDING THE VALUE OF RESORCIN, ICTHYOL, AND LANOLIN IN CUTANEOUS DISEASES.

Resorcin.—In eczema it is rarely of benefit, but possesses some power over the itching. For this purpose a six per cent. ointment is useful. In tinea sycosis it has proven of some value in ten to twenty per cent. strength. In tinea tonsurans it is inferior to the remedies usually employed.

In seborrhœa and alopecia dependent upon this disease, a lotion consisting of a drachm of resorcin, one or two drachms of castor-oil, five minims of Peruvian balsam, and four ounces of alcohol, was of value. In tinea versicolor it was found less useful than a solution of hypophosphite of sodium. In psoriasis, and in one case of lupus erythematosus, the result was negative. In one case of superficial epithelioma a fifty per cent. ointment produced a good result; in a second case a fair result; and in a third the result was negative.

Ichthyol.—In a small proportion of cases of rosacea and acne vulgaris a ten to twenty per cent. preparation was found beneficial. In furunculus it acted with good results in three cases when applied as a twenty per cent. plaster; in the fourth case it had no effect. It was of service in psoriasis, and also in a case of lupus erythematosus. In favus it was used without effect.

Lanolin.—In some cases, as an ointment base, this is superior to the ordinary fats in use. Where a simple protective action is desired, it is inferior to vaseline, cold-cream, or lard. In chronic cases, where there is infiltration, and a degree of penetration is the object, lanolin is especially valuable. The main disadvantage of lanolin, as now manufactured from sheep's wool, is its strong sheepy odor. In a few acute and subacute cases of eczema, lanolin, for some reason, proved irritating. As a rule, however, it is bland and unirritating.

The meeting then adjourned.

Thursday, August 26th—Second Day—Morning Session.

The first paper, by Dr. G. H. Tilden, of Boston, was entitled

TROPHONEUROSIS OF THE SKIN CAUSED BY INJURY OF THE MEDIAN NERVE.

He described the case of a carpenter, wounded in the wrist by a saw four months before coming under observation. Three or four days after the infliction of the injury there was loss of the tactile sense, and a feeling of numbness in the last two phalanges of the fore- and middle-fingers. This steadily increased. Three weeks after the accident a bulla appeared upon the terminal phalanx of the middle-finger. Similar lesions have developed from time to time upon the last two phalanges of the fore- and middle-fingers. The bullæ appear every two or three weeks, and are unaccompanied by any subjective sensation. The skin over the affected phalanges is of a white color and of glossy texture.

Six weeks' treatment with the Faradic current caused decided improvement in all the symptoms. During this period only one bulla formed. He then stopped treatment and returned to work. Three weeks later all the former symptoms suddenly returned. It was suggested that an incision be made over the seat of injury with the view of determining the exact condition, and, if possible, remedying it. To this the patient did not consent.

The treatment of these cases consists in the use of electricity and the application of blisters over the seat of injury. A last resource is to cut down upon the affected nerve and endeavor to relieve any constriction or pressure upon the nerve which may be found. If no such condition is detected, resection of a portion of the nerve might be advisable, since complete section is not apt to be followed by spontaneous trophic changes, and since it has been found by some observers that resection of a portion of the affected nerve is sometimes followed by the arrest of the trophic changes.

Dr. James C. White, of Boston, read a paper entitled

NATIVE PLANTS INJURIOUS TO THE SKIN.

The speaker enumerated over fifty species which have irritating properties when brought in contact with the skin. With reference to rhus poisoning, the speaker said that the rhus toxicodendron was comparatively innocuous, while the rhus venenata was the most poisonous species of this plant.

Dr. H. G. Piffard, of New York, read the next paper, entitled

NOTES ON DRUGS,

in which he referred briefly to several recently introduced preparations.

Dr. F. B. Greenough, of Boston, then read

A FEW ADDITIONAL NOTES ON PSORIASIS.

The paper was supplementary to one presented at the last annual meeting of the Association. The author had attempted to obtain further testimony in reference to the general health of the patients affected with psoriasis. He found that, as a rule, patients with psoriasis were above par in general health and strength. He had records of twenty-nine cases out of 1,220 cases of skin diseases, giving a ratio of cases of psoriasis of two and one-third per cent. In twelve cases in which evidence could be obtained, four gave a decided history of the existence of disease in some member of the family. The fact that these cases showed such a high standard of general health he considered a strong argument against the possible connection between psoriasis and syphilis.

Dr. A. R. Robinson, of New York, related the history of a case of

CHONDROMA OF THE UPPER LIP.

The tumor occupied the right side of the upper lip of a man thirty-six years of age. It had been growing for two years, and was one inch in length by three-fourths of an inch in diameter. It was egg-shaped, the broad end having its seat in the submucous tissue, among the mucous glands. The mucous and cutaneous structures were freely movable over the tumor, which was sharply limited, somewhat encapsuled, and nourished by a small artery entering at the base. Microscopical examination showed the tumor to consist of embryonic, gland, and connective tissue. The gland tissue was formed of hypertrophied mucous glands and new gland tissue. The connective tissue was myxomatous, fibrous, and cartilaginous. There were several islands of cartilage, the largest being in the central part of the tumor. All varieties of normal cartilage were present, viz., hyaline, fibrous, and reticular, and also the variety met with in the heads of cephalopodes, namely, cartilage with ramifying or branched cells, *chondromes à cellules ramifiées.*

Dr. P. A. Morrow, of New York, read a paper on

KERATOSIS FOLLICULARIS, ASSOCIATED WITH FISSURING OF THE TONGUE AND LEUKOPLAKIA BUCCALIS.

The patient, C. O——, a sailor twenty-one years of age, came under observation in December, 1885. Five years previously, soon after beginning his seafaring life, he noticed a number of blackish points upon the back of the hands, some of which he squeezed out. Soon afterward these appeared upon other parts of the body. They improved when he was on land, but were aggravated when he was at sea. The entire surface of the body, with the exception of the face, palms, and soles, was

found to be the seat of the follicular disorder. The ducts of the sebaceous glands were occupied by comedo-like bodies projecting sometimes one-fourth to one-half an inch above the surface. From many of the follicles small white hairs protruded. The comedos, when pressed out, were hard and dry. The hard portion of the comedo was continuous with an adhesive substance dipping deeply into the follicle. There was no evidence of irritative or suppurative action. They were not accompanied with itching.

The tongue was large and rough to the touch, the surface was deeply fissured, the fissures extending to the submucous tissue. The buccal mucous membrane presented a bluish-white appearance, thickened and raised in places, forming distinct plaques which were superficially fissured. The patient stated that the tongue had been white and a little sore ever since he could remember. The absence of irritation or marked sensitiveness of the fissured organ was quite noticeable. Examination seemed to exclude the possibility of a syphilitic origin. The speaker referred to other cases which had been reported. He objected to the term icthyosis, since that suggests a disease of a different nature. He selected the term keratosis follicularis as more correctly expressing the pathological condition present, as well as indicating the anatomical seat of the disorder. Drawings representing the microscopical appearances of the lesions were presented.

Dr. J. E. Graham, of Toronto, Canada, presented a

CLINICAL STUDY OF SCLERODERMA.

The author first related the histories of two cases of this rare disease. The first patient, Mrs. R——, forty-seven years of age, had previously suffered from rheumatism. The hardening of the skin began in March, 1882, and was first noticed over the back of the neck. It gradually spread so that, in about ten weeks, the integument over the greater part of the body was affected. The movements of the limbs as well as those of respiration were impeded. The internal treatment adopted was liquor ferri iodidi and liquor arsenitis. A faradic bath over the surface of the skin was used. In six weeks the skin began to grow softer, and in ten months the patient was quite well. There has been no return of the difficulty.

The second patient, Mr. H——, forty-seven years of age, came under observation in May, 1886. There was a history of hereditary rheumatism. The disease had commenced some months previously. The first symptoms were stiffness of the limbs with œdema of the lower extremities; then hardening of the skin over the hips was noticed; this gradually spread and was accompanied with pigmentation. The treatment consisted in the administration of potassium iodide at first, and latterly of salicylate of sodium. There has been some improvement under this treatment.

In his remarks in connection with the disease, the speaker referred to the following points: 1. That the disease is found principally in temperate climates, and occurs in seasons when there are sudden changes in the weather. 2. That it is more closely related to rheumatism than has been supposed. 3. That although morphœa has in all probability a similar pathological origin to scleroderma, yet the clinical distinctions are so marked that at present it is expedient to treat it under a different name.

Dr. L. N. Denslow, of St. Paul, described a case of scleroderma in which benefit has followed the daily use of the constant current for six months.

Dr. Le Grand N. Denslow, of St. Paul, read a paper on

CARCINOMA CUTIS.

The skin of the right chest from the second to the seventh rib, and from the posterior border of the axilla to the median line, was covered with a nodular new-growth which presented no ulceration. Around the nipple the nodular mass reached a thickness of one inch. The older portions of the growth were covered with thickened epidermis and thick brown scales. There was slight enlargement of the axillary glands. The different nodules were not movable beneath the skin, but the whole mass was free from the fascia. The mass was the seat of occasional neuralgic pains. The duration of the growth was seven months. The patient died four months after coming under observation.

Dr. I. E. Atkinson, of Baltimore, said that these cases are exceedingly malignant. He mentioned a case in which the disease ran its course in two or three months. These cases are so malignant that it would seem that no operative procedure is justifiable.

Dr. R. W. Taylor, of New York, referred to two cases of hard chancre of the nipple in men, in which the induration was so marked that for a time they were looked upon as cases of cancer of the nipple.

Dr. I. E. Atkinson, of Baltimore, read a paper on

SCARLET FEVER AND SCARLATINIFORM ERUPTIONS FOLLOWING INJURIES AND OPERATIONS.

The following conclusions were presented: 1. Unprotected persons who have suffered injury or undergone operation are much more liable to scarlet fever than healthy individuals. 2. When an epidemic tendency to these symptoms prevails after injuries and operations, it may be concluded that true scarlet fever is present. 3. Septicæmia is occasionally accompanied with scarlatiniform eruption. 4. Medicinal eruptions, especially from cinchona alkaloids, may follow accidents and injuries.

DISCUSSION.

Dr. P. A. Morrow, of New York, mentioned the rash which often follows the use of antipyrine, and which frequently simulates scarlatina, although it is usually of a more measly character. Again, carbolic acid and iodoform dressings will often produce rash presenting the objective appearances of scarlet fever. The eruption known as the "doctor's rash," which appears upon the persons of sensitive individuals stripped for examination, was also referred to.

Adjourned.

FRIDAY, AUGUST 27TH.—THIRD DAY.—MORNING SESSION.

Dr. J. E. Graham, of Toronto, Canada, exhibited the specimens from a case of ainhum.

Dr. S. Sherwell, of Brooklyn, read the first paper, which was entitled

REMARKS AND QUERIES ON, AND AS TO, THE RELATIVE FREQUENCY OF MOLES AND THEIR PATHOLOGICAL CHANGES ON THE HEAD AND FACE.

In looking up the statistics of one of the institutions with which he is connected, he found that, in a period of eighteen months, he had seen forty-seven cases suffering with neoplastic and hypertrophic growths. In thirty-six of the cases the growths occupied the face and head. In eleven cases only were the growths found on the body and limbs. Seventeen of the cases, in which the growths were on the face, were classed as epithelioma.

Moles, and similar growths, while common on other parts of the body as well as on the face, yet in other situations seem less likely to undergo destructive pathological changes. The field electively most inimical to the presence of these growths, and destructive activity in them when already present, may be bounded thus: A quadrangle just taking in the lower lip, the corners of the mouth, extending back to the ears on both sides, vertical lines extending upward to about an inch above the supra-orbital ridge, united by another horizontal line. Of the space thus included, the vicinity of the eyelids and bridge of the nose was, in the author's experience, the most usual seat of these growths.

The most rational explanation for the frequency of these growths in the situations described, is the nature and abundance of the circulatory nutrition, which must favor

hyperplasia. If, however, we accept this, why should those errors of the capillary system, such as nævi, not oftener degenerate? He had frequently operated on these latter deformities, often causing much irritation, but had never seen more than a slight keloid change result. The speaker then referred to the special danger of malignant degeneration which attended the presence of moles in persons of advanced life.

In regard to treatment, he had come to the conclusion that when malignant action is either present or suspected, the combination of Volkman's curette, followed by the potential cautery, is the most efficient and easiest method of treatment.

Dr. I. E. Atkinson, of Baltimore, held that the probable explanation of the frequency of the presence of moles, etc., upon the face, as compared with other portions of the body, was that, when in this situation, patients seek relief on account of the disfigurement, while when covered with the clothing attention is not attracted to them.

Dr. R. W. Taylor, of New York, said that Dr. Sherwell was to be congratulated upon the clear manner in which he has called attention to the danger of these various growths upon the face in a person over forty-five years of age. Such growths are very prone to assume malignant action. In the same connection it may be remarked that any inflammatory mass upon the prepuce, particularly if the result of anterior lesion, should in old persons always be ablated.

Dr. W. A. Harcaway, of St. Louis, presented some

NOTES OF A CASE OF EXFOLIATIVE DERMATITIS (PITYRIASIS RUBRA?) WITH BULLOUS LESIONS.

The patient was forty-five years of age, stout, and somewhat nervous. The disease came on three weeks previously, after a night of fatigue and exposure. The following day a red patch appeared on the pit of the stomach. Others developed, soon running together, leaving no healthy skin between. There was very little scaling at first, and no moisture. The chest, arms, back, and thighs presented the usual appearances of pityriasis rubra. There was neither moisture, crusts, nor appreciable infiltration, the skin was shining and of a violaceous hue. In the morning a handful of scales could be gathered from the sheet, but they were not as large as usual. Three or four days after the first visit there appeared upon the thighs, abdomen, and buttocks a number of tense bullæ. Their appearance was preceded by a distinct chill, and followed by a moderate elevation of temperature. The blisters did not run into each other. The bullæ appeared in successive crops of not more than a dozen, each crop being preceded by a chill. Quinine was freely administered, and at the end of a week the bullæ ceased to appear. The patient gradually improved.

The writer thought that this and other cases which he had seen, showed diseases usually supposed to run a dry course, may, under certain circumstances, be complicated with lesions containing fluid.

Dr. G. H. Tilden, of Boston, reported

A CASE OF PROBABLE TUBERCULOSIS OF THE SKIN.

Dr. Le Grand N. Denslow, of St. Paul, made a supplementary report with reference to

THE TREATMENT OF ACNE BY THE USE OF SOUNDS.

At the last meeting he had reported five cases in which this plan of treatment had been of value. Four of these cases were adults, and all had remained well. The fifth case was that of a boy about fourteen years of age, and in this case relapse had occurred.

A communication with reference to the organization of a congress of American physicians and surgeons was received, and the following Committee of Conference, to report at the next annual meeting of the Association, was appointed: Drs. H. G. Piffard, of New York; F. B. Greenough, of Boston; R. B. Morison, of Baltimore; G. H. Tilden, of Boston, and Le Grand N. Denslow, of St. Paul.

The following officers were elected:

President—Dr. H. G. Piffard, of New York.

Vice-Presidents—Dr. F. B. Greenough, of Boston; Dr. R. B. Morison, of Baltimore.

Secretary—Dr. G. H. Tilden, of Boston.

Treasurer—Dr. Le Grand N. Denslow, of St. Paul.

The Association then adjourned to meet at the call of the Council.

Correspondence.

ICE CREAM POISONING.

To the Editor of The Medical Record.

Sir: In your review of my report to the Michigan State Board of Health on the analysis of the Lawton cream, there are a few statements which I hope you will permit me to comment upon.

In the first place I have never "claimed," as you say, "to have discovered the *fons et origo* of the poison in a new ptomain," etc. I hope that I am sufficiently acquainted with the nature of ptomains to know that they are produced by fermentation or putrefaction. The *fons et origo* of the poison must be the ferment which produces the ptomain. Of this I speak as follows: "How the special germ which produces the poison found its way into the Lawton cream I cannot say; but that it was present in the milk, or was contained in the eggs used, I think cannot now be doubted."

I desire it to be distinctly understood that I do not claim that tyrotoxicon has existed in every ice-cream which has produced untoward effects upon man. Mineral poisons have been found in ice-cream, and Dr. Bartley's idea that the poisonous properties of the cream which he examined were due to the use of putrid gelatine is a rational theory. The poisonous principle in this case might arise from the decomposition of the gelatine itself; or with the gelatine there may be introduced into the milk a ferment, by the growth of which a poison might be produced. But the Lawton cream had no gelatine or mineral poisons either in it.

In view of Dr. Morrow's letter in your issue of July 27th, I am sorry that you did not refer to my proof, that the vanilla used in the Lawton cream was not poisonous. The vanilla which remained in the bottle was sent to me, and on page 4 of the report you will find the following: "Mr. Novie and I took at first thirty drops each of the vanilla extract. No ill effects following this, Mr. Novie took two teaspoonfuls more, with no results. This settled the question of the poisonous nature of the vanilla more satisfactorily than could have been done by a chemical analysis." Moreover, as you will see from page 7, by adding a piece of the solid portion of the Lawton cream, about the size of a filbert, which had been washed with distilled water to normal milk, and then following the details of the Lawton caterer, with the exception that no flavoring whatever was used, I made a cream which was highly poisonous.

I find that in my report the time which elapsed between the making of the vanilla custard and its freezing is stated only indirectly, and that by giving the time during which I allowed the custard which I made to stand before packing in ice. The testimony on this point, as obtained from Lawton, from different persons, varies as to the exact time, some placing it at one hour and a half, others at four hours. I took three hours as the probable time, as you will see from my report.

I have recently received a letter from Lawton which throws much light upon this subject. Permit me to give the following extract: "The cream was frozen in the back end of a wooden building owned by C. M. Morrick,

and located on Main Street. It is surrounded by shade, has no underpinning, and the sills have settled into the ground. There are no eave-troughs, and all the water falling from the roof runs under the building. The street also largely drains under the building, the streets on two sides having been raised since the building was erected. The building had not been occupied for a number of months, consequently had no ventilation, and what is worse, the back end (where the cream was frozen) was last used as a meat market. The cream which was affected was that portion last frozen, consequently it stood in an atmosphere more like that of a privy vault for from one and a half to two hours before being frozen. It seems to me that anything so sensitive to surroundings as milk could not escape being affected by such surroundings."

The above, written by an unprofessional man, and written after my report, is, to my mind, very valuable information.

You regret that I have not given the chemical properties of tyrotoxicon. These, so far as I know them, are given in *Zeitschrift für physiologische Chemie*, B. x., H. 11. As they had been presented to the Board a year ago, I did not repeat them; but I gave the reference, and any chemist can find them.

You think that my theory does not explain the occurrence of poisoning, with the production of identical symptoms, from the use of other alimentary preparations, as pastries, puddings, etc., in which only a minimum quantity of milk is used. Does the fact that a ferment will produce a poison by its growth in milk prove that the same ferment will not produce a poison in pastries, puddings, etc.? There are present the same foodstuffs—albumen, fat, and sugar. Or does similarity of symptoms always prove the presence of the same poison? In a general way, may we not say that symptoms arising from poisonous cheese or ice-cream are identical with those of arsenic? At least most physicians, in treating such cases, have almost invariably diagnosed arsenical poisoning from the symptoms.

That there is no better food for children than good milk, I will claim as earnestly as anyone. But that unclean nursing-bottles or other foul receptacles of milk are beneficial to the health of children I doubt, and I simply suggested the possibility of the poison being generated in such vessels.

As to the direct agency of bad milk in causing cholera infantum, and the desirability of withholding milk as food during the course of the disease—and this is the only time in which I have recommended that milk be withheld—I am now collecting evidence. I will only say that several physicians in this State are now treating cholera infantum in accordance with the suggestions of the report, and they claim to be very successful, and I have not heard of any "boom for the venders of artificial foods" being created thereby. The use of a little rice-water or mutton-broth during a short course of cholera infantum can hardly lead to a great boom for the venders of artificial foods.

Respectfully,
V. C. VAUGHAN.

INTRAVENOUS INJECTION OF SALT SOLUTIONS.—Dr. F. B. Harrington has tabulated all the recorded cases of transfusion with salt solutions. He recommends that the solution be made as follows: Sodii chloridi, 6 grammes; sodii bicarbonatis, 1 gramme; aquæ destillatæ, 1,000 grammes. The solution should be warmed and kept at a temperature between 100° F. and 104° F. The solution should enter the circulation at a low pressure, and its effect on the heart should be carefully watched. Gravity pressure is safer than a syringe, an elevation of from one-half to three feet being sufficient. The amount used would depend upon the effect upon the circulation, but it may be from one to four pints.—*Boston Medical and Surgical Journal*, May 27, 1886.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August [illegible], to [illegible], 1886.

MIDDLETON, P., Major and Surgeon. Assigned to duty at St. Francis Barracks, St. Augustine, Fla., as Post-Surgeon. S. O. 126, Division of the Atlantic, September 2, 1886.

LA GARDE, L. A., Captain and Assistant Surgeon. Upon departure of Third Infantry from Fort Ellis, M. T., to proceed to Camp Sheridan, Mammoth Hot Springs, Wyo. Ter., and report to the Commanding Officer for duty, relieving Assistant Surgeon Pilcher. S. O. 87, Department of Dakota, August 27, 1886.

CRAMPTON, L. W., Captain and Assistant Surgeon. Relieved from further duty at Bellevue Rifle Range, and granted leave of absence for one month, to take effect before rejoining his proper station (Fort Bridger, Wyo.). S. O. 108, Department of the Platte, August 28, 1886.

PILCHER, JAMES E., First Lieutenant and Assistant Surgeon. When relieved by Assistant Surgeon La Garde from duty at Camp Sheridan, to return to his proper station (Fort Custer, M. T.). S. O. 87, Department of Dakota, August 27, 1886.

WOOD, L., First Lieutenant and Assistant Surgeon (recently appointed). Ordered to report by letter to the Commanding General, Department of Arizona, for assignment to duty. S. O. 202, A. G. O., August 31, 1886.

MASON, CHARLES F., First Lieutenant and Assistant Surgeon. Relieved from duty in Department of the East, and assigned to duty in Department of Arizona. S. O. 203, A. G. O., September 1, 1886.

WALKER, FREEMAN V., First Lieutenant and Assistant Surgeon (recently appointed). To report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 203, C. S., A. G. O.

Official List of Changes in the Medical Corps of the United States Navy for the [illegible] ending [illegible], 1886.

CLARK, JOHN H., Medical Inspector. Ordered to special duty, Portsmouth, N. H., and Widow's Island.

KINDLEBERGER, D., Medical Inspector. Ordered to Hospital, Washington, D. C., October 1, 1886.

GIHON, A. L., Medical Director. Ordered to Hospital, Mare Island, Cal., October 15, 1886.

ROBINSON, SOMERSET, Medical Inspector. Detached from Hospital, Mare Island, Cal., October 15, 1886, and wait orders.

SPEAR, J. C., Medical Inspector. Ordered to Naval Laboratory, New York, September 28, 1886.

BLOODGOOD, DELEVAN, Medical Director. Ordered to Hospital, Norfolk, Va., September 29, 1886.

TAYLOR, J. Y., Medical Director. Ordered to Naval Laboratory, New York, September 29, 1886.

DEAN, R. C., Medical Director. Detached from Naval Hospital, New York, and wait orders.

SIMON, W. J., Surgeon. Detached from U. S. S. Constellation, and special duty at Naval Academy, Annapolis, Md.

HENRY, C. P., Assistant Surgeon. Ordered to Hospital, Philadelphia, Pa.

FITTS, H. B., Passed Assistant Surgeon. Detached from Hospital, Philadelphia, Pa., and wait orders.

STONE, E. P., Assistant Surgeon. Ordered to Receiving Ship New Hampshire.

DICKSON, S. H., Passed Assistant Surgeon. Detached from the Naval Academy, October 1, 1886, and ordered to Navy Yard, Washington.

LIPPINCOTT, J. G., Passed Assistant Surgeon. Ordered to Naval Academy, October 1, 1886.

SHIPPEN, E., Medical Director. Detached from Naval Hospital, Philadelphia, and ordered to attend officers of the Navy and Marine Corps at Philadelphia not otherwise provided with medical aid.

HORD, WILLIAM T., Medical Director. Detached from Examining and Retiring Boards at Washington, October 5th, and ordered to Naval Hospital, Philadelphia, Pa.

DEAN, R. C., Medical Director. Ordered to duty as member of Examining and Retiring Boards at Washington, October 5, 1886.

BRANSFORD, J. F., Surgeon. Detached from U. S. S. Iroquois, and ordered to Naval Hospital, New York.

HALL, C. H. H., Passed Assistant Surgeon. Detached from Naval Hospital, New York, and ordered to Naval Hospital, Yokohama, per steamer of 21st inst.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 4, 1886:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	[illegible]	1
Scarlet fever	1	1
Cerebro-spinal meningitis	[illegible]	[illegible]
Measles	[illegible]	[illegible]
Diphtheria	[illegible]	1
Small-pox	0	

HOW TO PRESERVE THE DEAD BODY.—Dr. H. Speier, of Duluth, Minn., writes: "In reply to the inquiry of Dr. Kennedy in THE RECORD of August 7th, I will briefly give him the method for preserving bodies invented a few years ago by Wickersheim, of the Anatomical Museum of Berlin. The process is simple and cheap, and the inventor claims that by it the color, form, and flexibility of dead animal bodies and all their tissues are completely preserved. He says that after several years sections for scientific or legal purposes can be made, decomposition and even foul odor being entirely absent. The preserving fluid is made as follows: Take 3,000 grammes of boiling water, dissolve in it 100 grammes of alum, 25 grammes common salt, 12 grammes saltpetre, 60 grammes potash, and 10 grammes arsenious acid. After cooling, filter the solution. To 10 litres of this neutral, colorless, and odorless fluid add 4 litres of glycerine and 1 litre of methyl-alcohol. Inject the body with the preserving fluid, then immerse it in the same for a few days. Rub and dry the body, envelop it in a sheet soaked in the same fluid, and place in an air-tight receptacle. If Dr. Kennedy ever uses the method given here, I should like to hear what results he gets from it."

LABOR AMONG THE NATIVES OF NEW GUINEA.—The Rev. W. S. Lawes describes, in the *Australian Medical Gazette*, of June 15, 1886, some of the customs among the natives of New Guinea in sickness and childbirth. When labor pains come on, the mother of the woman and her mother-in-law come—the former to assist the woman, the latter to receive the child. A rope is made fast to the roof and hangs at a convenient distance from the woman, so that she can hold on to it when the pains come on; her mother sits behind her, so as to support her back and head. They are always delivered sitting. When the birth is difficult (a rare occurrence even in *primipara*), a ceremony is gone through, which consists of the assembled friends performing an incantation and calling upon their ancestor god to help. It is only in extreme cases, such as malpresentation, that they endeavor to pull the child away with force. When the child is born it is received by the expectant grandmother, who sucks its mouth immediately. The cord is not cut until after the placenta has come away; when it has come the grandmother works the cord by her finger-nails until it becomes thin; she then cuts it with a piece of flint; it is not tied. The previous manipulation of the cord prevents loss of blood. The distance from the navel at which it is cut is measured on the child's thigh. Among the Motu tribe, mother and child remain in the house until the cord drops off, usually on the fifth day. Then the mother takes the child down into the sea and bathes herself and it. At Hood Point the mother takes the child in her arms as soon as it is born and plunges with it into the sea. The object is said to be to make it fearless of the sea. They are a tribe of fishermen. In the Gulf, to the west, they take their new-born babe to meet the breakers, and let the surf break over it. The same reason as above is given for it. Until the mother is able to feed her child, relatives and neighbors suckle the child. From the time the navel cord drops off, the child is given ripe bananas, when procurable, and very soon yams and other vegetables—all chewed first by mother or sister. Milk of animals is unknown among the natives as an article of diet. The children are really never weaned—a big boy, three years old, will come in from play and run up to his mother for a drink. The husband does not cohabit with his wife until the child is six or eight months old, and sometimes not until it is able to run about. They believe that it would have a prejudicial effect upon the child to do so.

SWALLOWING A CENT.—Dr. J. L. Gardner, of Voluntown, Conn., writes that he was called to see a child, two years of age, who had got a copper cent in the pharynx, whence it was pushed into the œsophagus by the mother in her efforts to relieve the choking. The writer pushed it down into the stomach, and then administered castor-oil for some days. The coin had not been passed, however, at the end of four weeks, and the child seemed to be suffering no ill effects. An irregular practitioner in the neighborhood was called in and informed the mother that there was no danger, as the stomach juices would eat up the coin. Dr. Gardner inquires whether any harm is likely to result from the lodgment of the coin in some part of the intestinal tract.

CULTURE OF VACCINE IN MUSHROOM JELLY.—Experiments have recently been made by the Finnish Medical Society in the cultivation of artificial lymph in sterilised mushroom jelly. The artificial lymph has also been dried and used for vaccination. A child was exhibited at one of the meetings who had been vaccinated by the artificial lymph in the arm. There were nine vesicles in three rows. They were all well developed, and did not present any dissimilarity, although two rows had been produced with lymph taken from different parts of the culture glass, and the third row with dried lymph from the same glass. Former experiments had not been so successful, owing to the resistance of the lymph to the effects of drying. The cultivation of the lymph has now been brought to a more satisfactory point.

NITRITE OF AMYL AS AN ANTIDOTE FOR OPIUM.—*L'Union Médicale* reports the case of a person who took two ounces of laudanum, and showed every symptom of opium-poisoning—coma, small pulse, feeble and infrequent respiration (six to the minute), coldness and cyanosis. Belladonna proved useless, while inhalation of nitrate of amyl immediately improved and ultimately restored the patient.

PERI-UTERINE INFLAMMATION.

A STUDY OF PERI-UTERINE INFLAMMATION IN ITS RELATION TO SALPINGITIS, BASED UPON SIXTEEN CASES OF EXTIRPATION OF THE TUBES AND OVARIES, OCCURRING IN BELLEVUE HOSPITAL.

BY WILLIAM M. POLK, M.D.,

THE purpose of this paper is the consideration of those inflammatory masses found about the roof of the vagina, generally to the sides of the uterus, sometimes behind, and but very rarely in front of it. These masses are described under the heading "Pelvic Cellulitis" and "Pelvic Peritonitis" in the works usually used by the English-speaking members of our profession, and from the time they were first noted and described have been the subject of controversy.

Let it be understood that I exclude the results of hæmatocele, of fibroid tumors of the uterus, of tubercle and cancer, of extra-uterine pregnancy, and disorders of the rectum and bladder, conditions which may simulate the masses in question, but with histories and signs so different as to preclude the chances of confounding them at the bedside.

At first, as is seen in the papers of Doherty, read before the Obstetrical Society of Dublin, May 5, 1842, and that of Fleetwood Churchill, read before the Surgical Society of Dublin, January 28, 1843, all that was claimed was, that such masses were found in parturient women chiefly, but in the non-parturient occasionally; and as Churchill, in particular, pointed out that they resulted sometimes in an abscess, no attempt seems to have been made to differentiate the point of development for such morbid products, the writers in the main resting satisfied with the assertion that they belonged to the uterine appendages. As Churchill says: "I shall therefore speak of the disease as affecting the uterine appendages, be they Fallopian tubes, broad ligaments, or ovaries, one or all—nay, as extending itself sometimes to the neighboring cellular tissue." Years before this the affection had been described imperfectly by La Motte and Puzas; but it was not until the times of Aran, Nonat, Bernutz, and Simpson that a determined effort was made to settle the important question as to the point of development and the line of propagation of these products of inflammation. Nonat maintained that the point of development was the cellular tissue adjacent to the uterus, beneath the peritoneum. Bernutz denied that any peri-uterine inflammatory mass—phlegmons as they were called—could belong to the cellular tissue immediately adjacent to the uterus, but admitted the possibility of implication of this tissue secondary to a pelvic peritonitis, and conceded the existence of phlegmons in the cellular tissue between the layers of the broad ligaments—his conclusions being that the peri-uterine masses, which during life presented all the symptoms of the so-called "peri-uterine phlegmons" or "cellulitis," were formed by the pelvic viscera being matted together by peritoneal adhesions, and, consequently, that such masses were in the peritoneal cavity.

His words are: "I find that the tumor found after death is formed by various intra-pelvic viscera being matted together as a consequence of the inflammation," and concludes that inflammation of the pelvic peritoneum is always symptomatic, that it is generally so of inflammation of the ovaries or tubes, and, comparing the post-mortem lesions with the symptoms, he is led to the belief that the majority of the more important symptoms are attributable to pelvic peritonitis, while those of the uterine and tubo-ovarian affection, although of much more importance, are very obscure. He then goes on to relate a number of cases to corroborate his views—several of the series, notably the first, being particularly interesting to us now, as they so clearly illustrate pyosalpinx and pelvic abscess as a direct result of the tubal inflammation.

These conclusions have been singularly verified by the observations of the present day, and Bernutz may be said to be, if not the first, at least the most dogmatic and precise advocate of tubal disease as a factor in the pelvic disorders of women.

It was not to be supposed that his statements would pass unquestioned. They were combated, chiefly by the English school, mainly by Sir James Simpson. The condition which Bernutz described was one so rarely fatal that but few chances of post-mortem examinations in the early stages of the disease were offered. Where the cases did die, it was in consequence of the disorder passing on to the stage of abscess, and in them the involved tissues were so altered and intermixed with false membrane that it was difficult, and even impossible, to determine the precise origin of the inflammation. On the other hand, his opponents had many opportunities among the numerous deaths from puerperal inflammation to demonstrate the existence of inflammatory swellings in the area of cellular tissue adjacent to the uterus. Still, enough was accomplished to make it certain that the masses in question were sometimes in the peritoneal cavity, that possibly they might be the result of the extension of salpingitis, and that they might end as intra-peritoneal abscesses. Out of this grew an attempt to differentiate the conditions clinically, and by some writers the lateral peri-uterine masses were classed as instances of cellulitis, while those posterior to the uterus were classed as instances of peritonitis, but still the tubes were largely ignored. Then came certain observations made by Emmet and Schultze, to the effect that the cellular tissue of the utero-sacral ligaments was often involved, so that retro-uterine masses were by some again regarded as instances of cellulitis, and were called "parametritis posterior." Here the subject rested when Mr. Tait began his work. Then, for the first time, the views of Bernutz were put in the way of verification, for it became possible to check the results of bimanual vaginal examination by direct digital exploration of the intra-pelvic regions.

In the winter of 1883 Dr. Emmet presented to the Obstetrical Society of New York several specimens of diseased tubes which Mr. Tait had given him; and, in answer to questions as to the method of diagnosis, said that the tumors which such tubes and their surroundings made in the pelvis were regarded by Mr. Tait as identical with those which we in this country had viewed as due to "cellulitis" and "peritonitis" (see "Obstetrical Society Report," December 5, 1882). A few weeks later (December 21, 1882) Dr. Gaillard Thomas read a paper

[illegible] Society of Physicians and Patholog[illegible] Washington, June 15, 1886.

before the Academy of Medicine, reporting four cases which he viewed as corroborating this and other positions of Tait.

Dr. Wylie, January 15, 1885, read an interesting paper bearing on the subject before the New York Academy of Medicine, and has since followed it by another before the New York State Society. In both he commits himself to a belief in the identity of so-called chronic cellulitis and salpingitis. It is plain, then, that the opinion is rife.[1] It only remains to substantiate it. After hearing Dr. Emmet's statement and reading Dr. Thomas' report, my attention was fixed upon all such cases that came before me. My ward in Bellevue Hospital is the recipient of many patients suffering from "cellulitis" and peritonitis, of all origins and in all stages; the sufferers coming there are such (working-women) as are peculiarly exposed to the causes of pelvic inflammation. My conclusions gradually shaped themselves in the direction indicated by the English surgeon, so that during the winters of 1883, 1884, and 1885, I shifted my position to the doctrine that tubal disease is the principal factor in so-called pelvic cellulitis and pelvic peritonitis, adopting in the main the central idea enunciated by Bernutz twenty-five years ago. As time has passed, these views have become more firmly impressed upon me, so that now I regard perituterine inflammation as a dependency of salpingitis, and hold with Bernutz that in the symptomatology of these masses "the majority and the more important symptoms are attributable to pelvic peritonitis, while the uterine or tubo-ovarian affection, although of much more importance, is indicated only by obscure symptoms."

The salient question then is this: What are the inflammatory masses commonly met with about the uterus and the broad ligaments? Are they the result of parametritis (pelvic cellulitis), derived directly from the uterus and vagina, through the medium of the parenchyma, the lymphatics, or the veins, or are they the result of a perimetritis (pelvic peritonitis) derived from the uterus through the medium of the tubes? Owing to the inroads of surgery upon the pelvis this has become more than ever a grave question.

In this inquiry the position which I desire to occupy is this:

First.—That the inflammatory masses commonly found about the uterus, and which are described under the headings "Pelvic Cellulitis" and "Pelvic Peritonitis," are the result of salpingitis, plus peritonitis—the tubal disease being the direct result of disease of the uterus; that such masses are composed of the tubes and ovaries, with sometimes adjacent viscera, the whole being united by recent or organized lymph, the interspaces in acute cases, and sometimes in chronic cases, being filled with a serous exudate; that such swellings may be augmented by secondary infiltration of the adjacent sub-peritoneal connective tissue, but such infiltrations are subordinate in extent and influence to the peritoneal inflammation.

Secondly.—That these masses do not originate directly from the uterus or vagina as a *cellulitis*, *except* as the consequence of an *evident septicæmia* ingrafted upon those organs, after an abortion, a miscarriage, a labor, or after some operation; that even in such cases it is more than probable that salpingitis and peritonitis will be associated with and predominate over the cellular inflammation; that when these masses do begin as a cellulitis (the patient surviving the septicæmia), they rapidly tend to suppuration; that they end very rarely in the chronic indurations or swellings under consideration in this paper.

It is admitted by all that the vagina, and, chiefly, the uterus are the starting-points for these swellings; some hold that the ovaries are, but this I will not consider, as I do not think that the proofs of primary ovarian inflammation, outside of tubercular and cancerous deposits, being the initial factor in the production of the swellings in question, are conclusive, too few of the reports being explicit in excluding previous salpingitis.

The uterus and vagina being then the clearly admitted sources of the disorder, the question is in what way does the inflammation travel outward.

Through the tubes to the peritoneum; by way of the lymphatics, lymphangitis; by the veins, phlebitis; or directly through the parenchyma of the organs?

In one or the other of these ways, or by a combination of both, or all, inflammation travels from the genital tract outward.

In the first it gains direct access to the cavity of the peritoneum, in the other, by running in a more indirect way. Let us inquire as to which is the usual path. In septicæmia it travels by all. Excluding this condition it travels outward by way of the tubes. One of the most effective blows struck in favor of this last assertion was the discovery of the extreme rarity of acute metritis in the non-pregnant uterus. But the question of transmission by way of the lymphatics and veins is not so easily regulated.

Admitting, then, for septicæmia, a transmission by all the routes, will it apply to all of the puerperal inflammations or to all of the non-puerperal? The large majority of these masses are preceded and accompanied by symptoms of simple inflammation. Are such symptoms the expression of so serious conditions as lymphangitis and phlebitis? The history of such conditions, when developed in connection with the inflammations of other organs, forbids us so thinking.

Let us look at this subject from the stand-point of analogy and then examine the facts bearing upon it.

When an inflammation is started in the vagina, as in gonorrhœa, or from any irritant substance, it is a matter of daily experience that it tends to follow the mucous membrane into the uterus, and it would be singular if that inflammation, after covering the endometrium, should stop at the tubal entrance. If those tubes are capable of admitting the passage of spermatozoa and ova, their natural office, surely they would seem the easiest path of transit of the usual inflammatory process found in the uterus. There is one very suggestive fact with this question which has been the subject of considerable thought on my part. It is this: If cellulitis is so common about the uterus, why is it so uncommon about other organs? Let us, in order that the analogy may be as perfect as is possible, look into the behavior of the cellular tissue adjacent to other pelvic viscera.

Take, first, the genito-urinary tract of the male, and pass in review all the inflammatory conditions to which that tract is subject—their course is definite, with frequent extension along the various mucous surfaces, but with rarely an implication of the cellular tissue about them.

Take the prostate gland, which, in point of structure, is more nearly allied to the uterus than any other organ, and see what the history of its inflammations is. How often do we find cellulitis as a result of inflammation?

Take the penis, a mass of venous sinuses, how often do we have phlebitis as a result of its inflammations; we *do* have implication of the cellular tissue immediately adjacent to the urethra, the sub-mucous tissue, but how often does it extend to the cellular tissue entering into the composition of the entire organ?

Given a gonorrhœa, or an inflammation the result of some traumatism, and see how it will extend to every mucous tract—to the kidney on the one hand, to the testicle on the other—and how rarely are any of the cellular planes about these various organs involved to any appreciable degree.

Take the bladder and study its inflammations, and certainly they are common enough. Look next at the rectum, affected, for instance, with the ulcers of dysentery, and how often will you find inflammatory swellings in the folds or at the base of the meso-rectum?

It is hard to understand that inflammation will behave so differently in these organs from that which occurs in connection with the uterus. It is much easier to believe that inflammation here will follow the same law, and travel in general along the mucous surfaces into the tubes and out at their extremities. Here a suggestive fact relates to the ureters. These canals pass through much of that cellular tissue, in their course across the floor of the pelvis, in which those upholding the doctrine of cellulitis have located these masses. If they are right, it is strange that the ureters are so rarely constricted; no other flaccid canal surrounded by indurated masses of new tissue would be likely to fare so well. With the masses in the peritoneal cavity these canals are simply pushed against the yielding pelvic floor. With such masses at the base of the broad ligament and about the cervix, constriction or compression of the ureters, with dilatation above the constriction, and the inevitable results to the kidney, would be a far more common condition in the female than post-mortem examinations now show us.

But, after all, such arguments, while useful and suggestive, are not conclusive. The facts of the autopsy and operating-rooms are the pivots of our faith in medical science.

Let me then call your attention to this fact: In a large number of post-mortem examinations made in the dead-house of Bellevue Hospital, it is noticed that, excepting those patients who have died of septicæmia, it is the rarest thing to find pelvic cellulitis, unless the cellulitis be clearly secondary to a previous inflammation of the pelvic peritoneum. On the other hand, nothing is more common than to find evidences of peritonitis about the ends of the tubes, and it is noticeable that in such cases the evidences of such inflammation diminish as you leave the extremities of the tubes; that the cellular tissue about the uterus and in the broad and utero-sacral ligaments does not present evidences of inflammation, or, if it does, such evidences are confined to that immediately underlying the peritoneum, and diminish and disappear as you approach the uterus. In these cases the tubes always show implication.

In other words, the post-mortem evidences of peri-uterine inflammation are common, and these evidences are such as to show that the inflammation was a product of salpingitis, and not secondary to cellulitis; and that if cellulitis were present, it was either secondary to peritonitis, or else was a lesion of septicæmia in common with those which belong to that disorder when originating in other structures of the body.

In this connection it is well to quote the words of the pathologist of the Woman's Hospital of New York, Dr. Coe.[1]

"Of half a dozen fatal cases of hystero-trachelorraphy and incision of the cervix, in which I have enjoyed the rare opportunity of studying carefully the sequences, in every instance the cause of death was acute, diffuse peritonitis. The inflammation could be traced straight up from the wound along the mucous membrane of the uterus as an endometritis, along the tubes as a pyosalpinx, and then to the peritoneal cavity. In none of these cases was there any evidence of acute cellulitis, although old cicatrices were not wanting." On pages 71–73 he makes other suggestive statements—speaking of the results of limited inflammation in the pelvis as observed after death: "My attention was early directed to the subject by Dr. W. H. Welch, who had for years been seeking positive proof of the existence of circumscribed indurations in the vicinity of the uterus resulting from cellulitis. Judging by a letter received from him a few days since, I infer that he is still sceptical as to their existence. I do not go as far as that. By far the greater number of these indurations are situated high up in the broad ligaments, and consist of cicatricial masses, mostly confined to the peritoneum, of tubes or ovaries surrounded by old adhesions, or occasionally of an imprisoned knuckle of intestine. The 'thickening' of the utero-sacral ligaments, so frequently alluded to in works on gynecology, has, when carefully dissected out, proved in my experience to be due, not so much to a disease of the connective tissue of these ligaments, as to a cicatricial condition of the peritoneum covering them. The induration at the bases of the broad ligaments have been the special objects of my search. I confess that I have rarely (perhaps half a dozen times) found such thickenings in the cadaver which could be referred to a pure and straightforward cellulitis." "In by far the greater number of cases, where a well-marked laceration of the cervix is present, there is absolutely no induration whatever in the broad ligaments."

Let me now offer the record of sixteen patients in whom the symptoms and signs present were those of "pelvic cellulitis" and "pelvic peritonitis," but in which abdominal section showed salpingitis, periovaritis, and peritonitis. In two of the cases there was slight œdematous swelling of the cellular tissue in the broad ligament, just beneath the spot at which an inflamed tube had rested; in the remainder the most careful examination failed to detect the slightest induration or swelling in any part of the cellular tissue that lay about the uterus or between the peritoneal layers of the ligaments.

The method of examination pursued was the following: Bimanual vaginal exploration of the uterus and its surroundings was employed in each case, both before and after the operation.

Before the operation indurated sensitive masses were present about the uterus, in each patient, and the mobility of the organ was impaired to a greater or less degree. After the operation the masses could not be found in a single case, and the mobility of the uterus was restored to about its normal range in nearly every instance. During the operation two fingers were placed astride the broad ligaments, every portion being thus readily explored. The entire pelvic floor was likewise examined by touch, and whenever the method seemed incomplete the opposing fingers of an assistant were placed in the vagina. Between the two it was impossible for any induration or thickening to escape detection.

An item of interest in many of the cases is the appearance of abortions and miscarriages as etiological factors.

Case I.—M. C——, aged twenty-six. This patient presented the symptoms of pelvic inflammation on entering the hospital. The cause was probably gonorrhœa, but the duration of it was difficult to determine. She presented extensive indurations in the region of both broad ligaments. Under treatment that on the right diminished, that on the left remained. Upon opening the abdomen chronic salpingitis, periovaritis, and peritonitis were found on both sides. The left ovary was as large as a lemon, and was firmly bound to the pelvic wall and the broad ligament. The tube and ovary on the right were slightly attached to the posterior face of their broad ligament.

Removing all these pelvic viscera, the masses and indurations disappeared, and the mobility of the uterus was restored.

Case II.—M. M——, aged thirty-four. Miscarriage two years *previous*; after that, pain in the left pelvic region continuous. Examination showed a sensitive mass in the region of the left broad ligament. The uterus was drawn to that side, and its mobility lessened.

Upon opening the abdomen salpingitis, periovaritis, and peritoneal bands were found; the bands attaching the tube and ovary to the broad ligament.

With the removal of the tube and ovary the mass disappeared, and the mobility of the uterus was restored.

Case III.—M. H——, aged thirty-seven. This patient was treated for several years for chronic cellulitis in various hospitals. On admission she had the symptoms of pelvic inflammation. Examination showed a mass in

[1] Transactions of Alumni Association, Woman's Hospital, 1886.

the region of both broad ligaments. Upon opening the abdomen chronic salpingitis with periovaritis was found, both tubes and both ovaries being bound to the posterior face of the broad ligaments, low down, by numerous and strong adhesions. With the removal of the tubes and ovaries the masses disappeared.

Case IV.—M. H——h, aged thirty-five. This patient had had two abortions, five months apart, between five and six years ago. Symptoms of pelvic inflammation were present since the last. Examination showed masses in the regions of both broad ligaments, extending to the lateral fossæ of Douglas. The uterus was retroverted and adherent to the pelvic floor. Upon opening the abdomen, chronic salpingitis and periovaritis were found on both sides, the tubes and ovaries being embedded in thoroughly organized new tissue. They were removed from the left side, but not from the right, the adhesions proving too strong. Examination showed that we had removed the mass on the left, but that on the right remained. But it was evidently due to the tube and ovary, and not to any thickening of the tissue of the broad ligament.

Case V.—S. D——, aged twenty-five. This patient had an enlarged and tender uterus which was retroverted. I used the sound several times in order to replace it before applying a pessary. After the last of these efforts she developed a mass on the right side of the uterus in the broad-ligament region, which was very sensitive. Nothing distinctive was found on the left side. With its appearance she complained of the usual symptoms of pelvic inflammation. A month's treatment diminished the mass slightly and relieved the symptoms, but as she clamored for an operation, I opened the abdomen and found the following conditions: On the right side a dilated tube with swollen walls. Its cavity contained a starchy, muco-purulent fluid. It, together with the ovary, was covered with recent lymph, and they were bound loosely to each other, both being attached to the posterior face of the broad ligament. There was no fluid exudation at that time, all that was present being recent lymph, some portions of it having attempted organization.

The left tube was dilated, its cavity containing the same kind of fluid as that found in the right. Upon this side there was but slight evidence of peritoneal exudation. Both ovaries showed periovaritis; the left but little; the right extensive implication. In this one the evidences of inflammation extended even to the cortex of the organ. It was enlarged as a whole. After both tubes and both ovaries had been removed, all trace of the mass previously found by vaginal examination disappeared. Here we have an admirable case for testing the reality of the condition known as cellulitis, for every symptom and every sign were identical with those given as dependent upon that disorder.

I class the case now as one of acute salpingitis—one, therefore, which no doubt would have recovered if its course had not been interrupted by an operation.

Case VI.—L. D——, aged twenty-eight. This patient came into the hospital with the symptoms of pelvic inflammation. Examination showed a mass in the region of the right broad ligament. Under treatment, this so far subsided that nothing remained of it but some obscure thickening of the tissues and a little sensitiveness to pressure. Leaving the hospital at the end of six weeks, she returned again at the end of six months. The sensitiveness had increased somewhat, and the thickening in the region of the base of the right ligament was more prominent. The abdomen was opened and the right tube and ovary were found diseased and adherent to the broad ligaments. (Chronic salpingitis, peritonitis, and periovaritis.) After the removal of this tube and ovary and the tearing up of the peritoneal bands, the thickening disappeared.

Case VII.—R. H——, aged thirty-nine; pelvic pain for years. On this account she had become an opium-eater. Examination showed induration and thickening in the regions of both broad ligaments, with exquisite sensitiveness. Upon opening the abdomen, chronic salpingitis, peritonitis, and periovaritis were found on both sides, the viscera being attached to the posterior face of the broad ligaments. With the removal of the tubes and ovaries the thickenings and indurations upon the two sides disappeared.

Case VIII.—A. L——, aged twenty-nine. This patient contracted gonorrhœa from her husband some years before admission to the hospital. She had been suffering from pelvic pain for three years. Examination showed sensitive masses on both sides of the uterus in the regions of the broad ligaments, the largest being on the right side. Upon opening the abdomen, chronic salpingitis, periovaritis, and peritonitis were found on both sides. Tubes and ovaries were attached to the posterior face of the broad ligaments by many adhesions. After the removal of these organs the masses could not be found.

Case IX.—P. G——, aged twenty-one. Constant pelvic pain for one year. She attributed it to the wearing of an ill-fitting pessary. A sensitive mass was found in the right broad-ligament region. Upon opening the abdomen chronic salpingitis, periovaritis, and the remains of a peritonitis were found. Tube and ovary were attached to the posterior face of the broad ligament. After the removal the mass disappeared.

Case X.—K. D——, aged twenty-five. This patient gave the history of frequent abortions. For two years she has suffered from constant pelvic pain. A small sensitive mass was discovered in the region of the left broad ligament. Upon opening the abdomen, hæmatosalpinx, the end of the tube being closed, periovaritis with atrophy of the organ, and the remains of peritonitis were found. The tube and ovary were attached to the posterior face of the broad ligament by new tissue. The upper border of the broad ligament was shortened. After the removal of the tube and ovary the mass disappeared.

Case XI.—O. S——, aged twenty-six. She had had several abortions. After the second or third, she could not recall which, she had an attack of pelvic inflammation. From that time to date she has suffered from constant pelvic pain. Examination revealed sensitive masses on both sides of the uterus in the broad-ligament regions, the largest on the right side. Upon opening the abdomen chronic salpingitis, periovaritis, and the remains of peritonitis were found, the conditions being best marked on the right side. The tubes and ovaries were adherent to the posterior face of the broad ligaments. After their removal the masses disappeared.

Case XII.—M. T——, aged twenty-four. This patient gave the history of frequent attacks of pelvic inflammation extending over a period of four years. She traced them to her last confinement. Examination showed sensitive masses on both sides of the uterus in the broad-ligament regions. Upon opening the abdomen chronic salpingitis, enlarged ovaries, and the remains of peritonitis were found. After the removal of the tubes and ovaries the masses disappeared.

Case XIII.—E. M——, aged twenty-seven. For three years had suffered from constant pelvic pain. The originating cause was obscure. Examination showed the uterus retroverted and bound down, and sensitive masses on both sides in the broad-ligament regions. Upon opening the abdomen, the uterus, the tubes, and the ovaries were found to be firmly bound to the pelvic floor by well-organized adhesions, the tubes and ovaries being likewise firmly attached to the posterior face of the broad ligaments. With much difficulty they were removed, the uterine adhesions being torn up at the same time. The masses could then no longer be found.

Case XIV.—A. W——, aged thirty-eight. This patient had suffered from pelvic pain for several years. The originating cause was obscure, but it seemed to have been

due to pelvic inflammation induced by treatment for posterior displacement of the uterus. Examination showed that the uterus was retroverted and bound down. Sensitive masses were discovered on both sides of the uterus in the broad-ligament regions. Upon opening the abdomen, the remains of pelvic peritonitis were evident. The uterus was fixed in the cul-de-sac. Chronic salpingitis and periovaritis were present on both sides, the tubes and ovaries being attached to the posterior face of the broad ligaments, but not to the pelvic floor.

The adhesions binding down the uterus were separated and the tube and ovary upon the left side removed, after which the mass upon that side could no longer be felt. The appendages upon the right side were not disturbed, owing to the accidental wounding of a vessel close to the uterus. There was prolonged and very troublesome bleeding. By the time this was controlled I did not think it wise to further prolong the operation, the patient's condition forbidding it. This case afforded me an opportunity to study the behavior of an inflamed tube after the adhesions binding it down and crippling it had been torn up. I carefully freed the right tube and ovary from the adhesions binding them to the posterior face of the broad ligament, and satisfied myself that they, as with the appendages on the left, represented the mass felt in this region through the vagina. I used a drainage-tube, as there had been a good deal of manipulation in the pelvis. This served the additional purpose of keeping the uterus forward.

The patient remained in the hospital nearly two months, and when I examined her just before her departure I found both sides of the uterus free from the masses, and from sensitiveness as well. The permanency of the improvement upon the right side is to be determined by time. But if salpingitis and peritonitis were the result of a retroversion, the correction of the latter in the manner employed in this case, together with the treatment of the tubes after the fashion employed with the right, might be found not only safe, but complete and satisfactory. Upon this subject I hope soon to present further observations. I will merely say here that I am convinced that the only reliable treatment for a displaced and adherent uterus is to be found in abdominal section. Whether the appendages are to be removed in all these cases is, in the light of this case, to me, an open question as yet.

Case XV.—A. H——, aged thirty-three. The patient gave a history of pelvic inflammation extending back to a miscarriage one year ago. She had been coming into the city from one of the suburbs for treatment. This involved a good deal of effort and some exposure, and coming, as it did, not only before, but after the treatment, was no doubt the immediate cause of the attack which brought her into the hospital. Be that as it may, when admitted she had the symptoms of acute pelvic inflammation.

The uterus was fixed at about the centre of the pelvis, and was anteverted. In the region of both broad ligaments and behind the uterus there was a solid mass of indurated and very sensitive tissue. The whole of the posterior half of the pelvis appeared to be filled in with inflammatory material.

When I opened the abdomen the following conditions were found to exist: The uterus was placed as described. The sigmoid flexure was attached to the fundus, and extended thence along the upper border of the left broad ligament to the pelvic wall. The uterus, with its broad ligaments stretching straight from it to the pelvic walls, divided the pelvis into two halves about equal. The posterior half was filled with exudation, formed and fluid, with enlarged and infiltrated ovaries, and with dilated tubes containing pus, that on the left being the larger. The fluid portions of the exudation were in parts purulent. This entire collection was roofed over with organized new-tissue, which extended from the fundus of the uterus and from the upper border of both broad ligaments backward to the posterior pelvic wall, striking it about one-third the way down. The rectum and sigmoid flexure were involved in this mass, but the coils of small intestines lay upon the roof of the tissue mentioned, free from every implication. The purulent portion of the exudation occupied the cul-de-sac of Douglas. In it was found the extremity of the left tube, but the opening into the tube was closed by recent lymph.

After much effort the left tube and ovary, together with all the fluid and some of the organized exudation, were removed. The tube and ovary on the right side could not be taken out. The result was this: Nothing remained of the mass felt through the vagina except a small mass in the region of the right broad ligament. This was clearly the tube and ovary on that side, as they were attached to the posterior face of that ligament. The left broad ligament and the regions posterior to the uterus were free.

This evidently was a case of pelvic abscess in an early stage, the point of origin having been the left tube.

Case XVI.—M. B——, aged twenty-three. She gave the history of pelvic inflammation extending over several years. The origin appeared to be in a miscarriage four years before entering the hospital.

Examination showed hard, sensitive masses in the regions of both broad ligaments, together with some sensitive induration in Douglas' cul-de-sac.

Upon opening the abdomen, chronic salpingitis, periovaritis, and peritonitis were found on both sides.

The mass in Douglas' cul-de-sac was composed of the end of the right tube, which was firmly bound to the posterior face of the lower part of the uterus. The remainder of that tube, the left tube, and both ovaries were firmly attached to the posterior face of their respective broad ligaments. There was no thickening of either of these ligaments, nor any masses within their basic lines. The diseased viscera were so firmly attached in their different locations that it was impossible for me, with safety, to do more than remove a portion of the left tube. The masses therefore remained, but digital examination showed them to be made up of the tubes, ovaries, and peritoneal adhesions, the cellular planes being free.

Here, Mr. President, I must end my argument.

I am aware that while it may be thought conclusive as to the first proposition it may be deemed deficient as to the second. To this I must answer: If we admit the first, we virtually concede the second. On taking up this subject it was my intention to end it here, but further consideration induced me to proceed and aim at some practical deductions.

I will offer no apology for the observations which are to follow, observations which some may consider premature. First, because I am convinced of the correctness of my position; second, because I feel that the time has come when everyone who has facts with which to back his beliefs should not only present them, but should be willing to aid in working out the conclusions to which they point.

Having this object before me, I now pass to a hasty review of the pathology, etiology, symptoms, prognosis, and treatment of these tubal products.

First as to the *pathology*.

Acute stage.—The tumors themselves are made up of tube, ovary, and exudation; sometimes a coil of intestine is included, perhaps the omentum.

These masses of tube, ovary, etc., are, as a rule, attached to the posterior face of the broad ligament, sometimes well up, again low down, but may also be in direct contact with the uterus, attached to its side, or posterior face; sometimes in as close contact with the latero-posterior aspect of the pelvic wall, a free space existing between the mass and the uterus; then, again, you may have the entire region posterior to a broad ligament, from the pelvic floor to the brim, filled with the mass; these may be single, on but one side, but quite often they exist on the posterior face of both broad ligaments, and if extensive, by coalescing they may fill the whole of the pos-

terior portions of the pelvis. When they are small, the uterus is but slightly displaced; forward, if the masses are double; to one side, if single—that is, to the side opposite to that occupied by the mass. This displacement is in direct proportion to the size of the mass. A single tumor may so fill one side of the pelvis as to force the uterus completely to the opposite side, but always canting it forward to some degree.

In case the masses are on both sides and are large, the uterus is carried directly forward, the amount of displacement being directly proportioned to the size of the mass. It may fill the entire pelvis, crowding the uterus and broad ligaments against the anterior wall of the pelvis, or forcing them down upon the vesical and paravesical regions, the uterus being in a state of complete anteversion. This condition gives you the impression that the uterus is enveloped by the inflammatory mass. There is one peculiarity of these displacements which is worthy of notice, namely, that the uterus as a whole is pushed not only out of position horizontally, but is likewise pushed downward. Whenever the posterior half of the pelvis is thus completely filled, the calibre of the rectum will be encroached upon, a fact which demonstrates itself clinically by the constipation and tympanites present in such cases. In the formative or acute stages of these masses you will find an abundant supply of serous exudation filling the interstices between and about the viscera implicated, and this exudate is responsible for the boggy sensation first given the examining finger, and for the size and smoothness of contour presented a little later. This inflammatory mass not only contains, but is surrounded by, organized lymph thrown out by the implicated peritoneum.

The exudation at the periphery serves to circumscribe the mass, and thus stands as a barrier between the central inflammatory nidus and the general peritoneal cavity. Sometimes this proves ineffectual, and then to the picture heretofore confined to the pelvis we have general peritonitis added. Entering the mass, we find the evidences of inflammation best marked about the fimbriæ of the tube, or tubes, from where it can be traced directly into their cavities. A word in reference to the exact condition of these tubes. The walls are thickened from inflammation and infiltration. As a rule they are dilated; sometimes to the dimensions of the small intestine, but generally to a less degree. The distention is, of course, greatest in the infundibular portions. In view of the fact that the end of the tube represents the centre of the extra-uterine inflammation, it is of importance to see just how it is placed. Its normal position is in fairly close relation with the outer and posterior aspect of the ovary, thus about midway the posterior face of the broad ligament, but this is subject to many variations, usually the result of inflammatory process. Be this as it may, we find the end of the tube in the inflammatory mass under consideration, the ovary, as a rule, being close by. But it may be attached to the pelvic wall, to the floor of the pelvis, to the brim of the pelvis, to the side of Douglas' cul-de-sac, to the rectum, to the sigmoid flexure, to the cæcum, to the posterior face of the broad ligament, to the uterus, and even to the bladder. Thus we see that while the centre of the intraperitoneal inflammation generally is the posterior face of the broad ligament, and is in immediate relation with the ovary, it may occupy a number of widely separated points.

The attachments at the pelvic brim, and even in the iliac fossæ, would seem to be confined to cases in which the uterus is enlarged to a considerable extent, though in one of my observations this was not the case, it being of about normal size.

If we see the tubes while in this, the acute stage of inflammation, the usual evidences of inflammation of a mucous tract will be noticed, and these evidences can be traced into the uterus to its mucous membrane. The tubes will be distended, and there will be fluid in them proportional to the amount of distention, and this fluid will vary in its appearance, and even position, according to the nature of the inflammation coming from the uterus. If that be infectious—as, for instance, in gonorrhœa or septicæmia—it will be more or less distinctly purulent; if, on the other hand, the inflammation be non-infectious, it will be muco-purulent, or chiefly mucous. This fact, the distention of the tubes, and the muco-purulent character of the contained fluid in this the acute stage of the pelvic swellings under consideration, is of importance in its bearing upon the question of treatment. The amount of tubal distention would seem to depend upon the perfection of the closure of its outer end.

The ovary may be said to be always implicated in this peritoneal inflammation, the fimbria which attaches it to the tube forming a ready transmitter of the process from the tube; but the extent to which it is involved must depend upon its proximity to the tubal opening and upon the degree of the inflammatory process. The limits of this paper will not permit more than a passing allusion to the changes effected in these organs in any stage of the inflammatory process. They suffer but little in the early stage, the changes being most marked on the capsule. This is covered with lymph or pus, as the case may be; and if the septic element largely predominates in the inflammation, the organ as a whole will be softened and the lymphatics leading from it will contain purulent lymph. As briefly as possible I will now trace the sequences of this the acute stage of these inflammatory masses.

Chronic stage.—What are the after-effects? This question resolves itself, first, into the consideration of the subsequent course of the inflammatory process, and, next, its effect upon the organ involved.

As to the subsequent course, this differs in no essential from inflammation of other structures and surfaces, and depends upon the state of the general health and the nature of the infecting element. We have:

Resolution, organization, and suppuration.

It is doubtful if the effects of a peritoneal inflammation ever disappear entirely, the peritoneum in this respect resembling the pleura. Still, in the lesser forms, nothing may remain but some thickness of the membrane. On the other hand, numerous dense and extensive adhesions and thickenings may result.

Lastly, suppuration may take place and an abscess be formed. Now just here let it be understood that the evidence of frequent suppuration in these masses is abundant, and it is clear that the purulent collection may be without the tube, the tube opening into it, or entirely within it; but in general it appears that even when within the tube its outer wall is either some one of the pelvic viscera, usually the ovary, or else some part of the pelvic wall or floor. I could cite numerous recorded cases to prove this. I will, by way of illustration, mention three that have recently come under my observation.

Case I.—W——. November, 1885. Right tube the size of a large walnut; the fimbriated end adherent to the pelvic wall just behind the spine of the ischium. Pulling it from this attachment the cavity of an abscess was opened. The wall of this cavity was made up chiefly of the outer expanded end of the tube, but the pelvic wall at the point of adhesion formed a part of it. The peritoneum at that point was eroded, showing that perforation in time might have occurred.

Case II.—A. W——. March, 1884. A fistulous opening just below Poupart's ligament on the right side; another lower down on the inner side of the thigh.

These sinuses unite on the surface of the psoas magnus muscle just above Poupart's ligament; from that point a single sinus extends to the brim of the true pelvis; there it passes into the cavity of the right Fallopian tube, whose fimbrated end is here closely united to the brim by adhesions. The cavity of the tube and the cavity of the uterus are freely communicable.

Case III.—In the report of Fleetwood Churchill, be-

fore quoted, a similar case is mentioned, on the authority of Mr. Lee.

Case IV.—Case XV., already recorded in this paper, is a fourth illustration of the method of the development of an abscess in this condition.

These cases are very suggestive as to the termination of tubal and intraperitoneal purulent accumulations, and point distinctly to the following: Given a salpingitis and peritonitis which goes on to suppuration, the location, and sometimes the direction of exit, of the pus is determined by the location of the extremities of the tubes. Now bear in mind the varying positions in which those extremities have been found, and we see that such abscesses may be found originating low down in the pelvis, or high up, even at the "brim," or in contact with some of the viscera, the ovary being the part generally involved. My observations have led me to the following conclusions as to the course of the pus: In the majority of instances it makes its way downward, and finds exit through the vagina most frequently; next, through the rectum. But it may take a course heretofore regarded as belonging to psoas and parametric abscesses—*i.e.*, through the anterior abdominal wall, above Poupart's ligament or below it on the thigh, and it may escape through the gluteal regions or into the peritoneal cavity. I will not detain you longer with further accounts of the results of these cases of purulent salpingitis, for there is nothing in the history of purulent accumulations in the peritoneum, arising from other sources, to invalidate the conclusions. My object is to bring forward distinctly the causative relation of salpingitis to these abscesses. There is one matter, however, worthy of consideration, namely, that it is possible and probable that some of these abscesses of tubal origin may have as their most extensive bed the cellular tissue about the uterus, in the broad ligament, or at the pelvic floor, being therefore extraperitoneal. The suppurating tube becoming attached at or near to the pelvic floor, as in the Cases I. and IV., or to the lower section of the posterior aspect of the broad ligaments, both common occurrences, perforation of the serous membrane and invasion of the cellular planes is a step easily taken.

Once there, the pus may wander in any of the directions that a collection primarily cellular may take.

For these reasons, then, I do not consider that any report upon the point or origin of a peri-uterine collection of pus (pelvic abscess) can be complete without a clear statement as to the position and condition of the fimbriated end of the tubes, no matter whether these abscesses be peritoneal or in the cellular planes.

From this it will be seen that it is not necessary to limit the abscesses of salpingitis to such as can be imprisoned beneath the broad ligaments of a retroverted uterus. Such abscesses can form in the peritoneal cavity, no matter whether the starting-point—the end of the tubes—be below or above these ligaments, in this respect resembling the behavior of an extra-uterine pregnancy.

As to the ultimate effect upon the organs involved. In this I will be as brief as possible, referring anyone who may care to look more deeply into the matter to the admirable monograph upon the subject of pelvic peritonitis by Julius Heitzmann, of Vienna.

The changes wrought in and about all the involved viscera are as varied as are the degrees of the inflammation. As already said, nothing may remain to show that inflammation has existed but some slight thickening of the peritoneum about the tubal extremity. On the other hand, dense masses of new tissue may be left, which for years distort and imprison the various organs.

First, as to the tubes. *They may escape any permanent injury. Their position and form, and the condition of all their coats—serous, muscular, and mucous—present nothing abnormal, unless it be some slight thickening of the fimbriæ.*

Then, again, they may be occluded, thickened, distorted, dilated, and bound to one or more of the adjacent viscera, to the posterior face of the broad ligament—their usual position—to the pelvic wall, or to the floor. Then they contain mucus or a muco-purulent fluid, a clear serous or a bloody fluid.

The ovary may be unaffected; but, again, it may be embedded in masses of tissue and clearly atrophied. Between these two extremes are many varieties of changes, but they are mainly thickening of the capsule and increase of the connective tissue, the result of the periovaritis. The so-called cystic degeneration may exist, but whether this be secondary to the periovaritis, which is a part of the pelvic inflammation, or due to independent changes in the Graafian follicles, I cannot say. The evidence points to an origin independent of salpingitis and peritonitis. One of the most interesting points in this subject is the result to the ovaries. Certainly in a large number of cases these organs are left in excellent condition, and just so long as any portion of the parenchyma is normal, that portion at least can perform the function of ovulation; and when we remember how small a portion may contain large numbers of Graafian follicles, it would seem that the ovary might undergo considerable change without destroying its ova-producing power.

I cannot banish the belief that there is no more reason for destruction of the ovary because of salpingitis and peritonitis than there is for destruction of a testicle because of epididymitis with inflammation of the tunica vaginalis; and yet it is to be borne in mind that permanent obstruction of the Fallopian tubes is the equivalent of destruction of the ovaries, so far as childbearing is concerned. In studying the results to the uterus, it should be understood that with the disappearance of the acute stage of the pelvic inflammation this organ, which has been displaced in one direction by the pressure of the masses of exudation, is now displaced in the opposite by the contraction of the same exudation, now diminished in bulk and organized. This is the case except in those instances in which the new tissue has extended far enough to bind the uterus in the position first given it. The mobility of the organ may not be interfered with if the inflammatory remains be slight, but if they are at all prominent it is fixed in direct proportion to the extent and length of the adhesions.

The uterus may then be retroverted and bound down—attached to the rectum and in the cul-de-sac—and this is rather a common pathological condition. It may be thrown into a position of anteversion or lateral anteversion by shortening of both, or one, of the utero-sacral ligaments. Another common displacement is the lateral one, dependent upon shortening of the broad ligaments, the fundus being the portion chiefly affected if the contraction be along the upper border, the cervix if it be along the base.

The condition of the structure of the organ is apt to be decidedly abnormal if with these displacements the tubes are in a state of chronic inflammation. This is most often seen in the retroversion. You have the body enlarged and sensitive, and from the cervix a purulent or muco-purulent discharge escapes.

The ligaments rarely escape some damage; they may be infiltrated, distorted, and shrunken, the condition of necessity exercising a decided influence upon the position and mobility of the uterus, as has already been pointed out.

With the uterus in a state of complete retroversion, or even flexion, it is possible for the posterior face of the broad ligament to become adherent to the pelvic floor, thus encapsulating the tube, but I cannot say that I have seen this often. When the inflammation is extensive about the rectum and dense masses of tissue remain, that viscus is constricted. I have seen three cases in which the calibre of the gut was narrowed to about the size of the index-finger; fortunately this is not often present. In one of my operative cases I found two cysts about as large

as a walnut situated in the meshes of the new tissue—a condition often noticed by others.

The picture here presented of salpingitis and its results is a varied one, but the graver lesions described are fortunately in the minority, the milder ones being those presented in the majority of the cases met with. It will be observed, Mr. President, that I have made no mention of those cases of pyo-, hydro-, and hæmato-salpinx in which the disease is confined to the tubes. This I have done purposely, for the reason that the condition is rare and is more likely to be confounded with hypertrophied ovaries and with beginning par-ovarian cysts than with the condition heretofore described under the heading of "Pelvic Cellulitis."

The *Etiology* of salpingitis and its peritoneal and visceral results centres about the inflammations of the inner lining of the body and neck of the uterus.

I know full well that several observers have claimed that even tubal inflammation, such as we see in post mortems, is the result of cellulitis, the process passing from the peritoneum to the tube, or from the ovary to the tube. To make this clear, the absence of an inflammation continuous from the mucous lining of the uterus to that of the tubes must be shown in cases of salpingitis, otherwise we are forced to the conclusion that these observers have reversed the current of the pathological sequences.

The line of propagation is undoubtedly a direct one from the mucous membrane of the uterus to that of the tube. The degree and character of the uterine implication determines, no doubt, the degree and character of the tubal and peritoneal inflammation, both, as in all tissues, being governed to a large extent by the conditions of the general system. Every patient, therefore, who has an endometritis, no matter how produced, has taken the first step toward a salpingitis and its results.

The *Prognosis* in this disease is a subject worthy of the most earnest study, for the reason that in the light of the brilliant success now obtainable in abdominal surgery there revolves about it the question of removing the tubes and ovaries—a mutilation to be avoided, unless imperatively demanded in the interest of the life and health of the sufferer.

If I have succeeded in establishing the identity of salpingitis and its results with the so-called pelvic cellulitis, we must admit that death is an exceptional result of this disease. It may be expected whenever evident septicæmia is at the bottom of the inflammation, or whenever a depraved constitutional condition is present, because in such a presence acute general peritonitis is apt to develop.

Pelvic abscesses are by no means an uncommon sequence, but, even with this, recovery is the rule—death, when it does come, being the result of pyæmia, of prolonged suppuration, or of acute general peritonitis. It is evident, then, that the large majority of cases of salpingitis and peritonitis do not die. But what is the ultimate effect of the disease upon the health and comfort of the individual? Experience shows that the majority of the cases get well, many getting so well that they not only suffer but little inconvenience, but are able to bear children subsequently. This is within the experience of everyone practising in the departments to which the disease belongs.

The "cure" is indicated by the disappearance of the pelvic indurations, but especially by the freedom of the patient from pelvic pain, backache, and endometritis, and the return of a menstruation such as is normal. If the masses remain after six or eight months' treatment, the "cure" of the patient is very doubtful, in spite of the fact that some such cases will, for years, experience but little discomfort. So long as the indurations remain, so long as there is tenderness about the uterus and the organ is not freely movable, the disease is present; and, upon provocation, is liable to spring up to its original dimensions, and go even beyond into the domains of danger and death. It is in these cases that we usually find sterility established as a permanency. They are instances of chronic salpingitis and peritonitis, with an implication of the ovary, usually in the form of peritonitis. Heretofore I have known them and described them as instances of "chronic cellulitis."

The symptoms and signs.—Believing that I have succeeded in establishing the relation between the disease of the tubes and the pelvic masses or indurations in question, I need not waste your time in discussing this part of the subject. I need merely refer you to the symptoms and signs set down in any recent work on pelvic cellulitis and pelvic peritonitis, asking you to bear this in mind—that whenever the symptoms and signs of septicæmia are unmistakably present, you must be prepared to recognize the possible existence of a primary cellular inflammation; but in the absence of such distinct symptoms and signs, to doubt its existence; and, granting its existence in any given case, never to lose sight of the fact that an inflammatory mass about the lateral or posterior aspects of the uterus is much more quickly produced by a salpingitis than by a cellulitis, so that even in the presence of septicæmia such masses are far more likely to be the result of the former than of the latter.

Touching the symptoms and signs of chronic cellulitis and peritonitis, they, with unimportant changes, should be labelled, "the symptoms and signs of chronic salpingitis and peritonitis." The question of the recognition of a cellular abscess versus a tubal or peritoneal abscess depends upon the close study of the antecedent history, but as the indications of treatment are the same in both we can afford to ignore the differentiation.

The treatment.—I have nothing new to offer you upon this subject. I only wish to reconcile differences. He who believes in the cellular origin and location of these evidences of inflammation inveighs against him that believes in their tubal origin, while he of tubal proclivities makes answer by showing the dilated, infiltrated, and pus- or muco-pus-containing tube. This may be a sufficient answer so far as settling the question of location of the inflammatory mass goes. But do all the advocates of tubal extirpation answer so well the next criticism of the opponent, namely, "If the cases which you show me in your wards and on the operating-table are cases fit for tubal amputation, how is it that so many identical cases get well in my hands?" Here the issue is now joined, and it is in the interest of progress that I have tried to show that there was a mutual misunderstanding.

The cellular advocates are wrong in their pathology and half right in their treatment. The tubal advocates are right in their pathology, but are half wrong in their treatment. The first is too little of a surgeon, the second is too much. I cannot answer for other countries, but in our own I am sure that the one permits many a woman to suffer, and perhaps die, who can only be relieved by the knife, while the other cuts too freely. A dilated tube with a cavity filled with fluid is his sufficient answer; but he fails to note the distinction between acute salpingitis and chronic salpingitis, and looses sight of the fact that the first and even the second may often be cured by simple methods—sacrificing, therefore, many tubes and ovaries which might better be left in place.

These two conditions are distinguishable, not only after opening the abdominal cavity, but before. *After*, by looking for the evidences of recent inflammation just described in the section on pathology. Before opening the abdomen, by a study of the patient's antecedents; for instance, the history of recurrent pelvic inflammation, or of constant pelvic pain, extending over a period of months or years, and associated with sensitive, indurated masses about the uterus, the mobility of the organ being lessened, are conclusions of chronic salpingitis. Rectal and vesical disorders being excluded, even less distinct evidences, provided they are associated with such a history, would be conclusive. But the *recent* development of a mass about the uterus in connection with any of the

causes known to produce salpingitis, and associated with pelvic tenderness and lessening of the uterine mobility, is to be regarded as the indication of acute salpingitis. The records of the dead-house and the bedside show conclusively how largely in the majority the cases of recovery in salpingitis are. It behooves us, then, to be slow in laying operative hands upon these tubes. In acute cases never, unless to cut short a peritonitis that threatens to become general; but in chronic cases, whenever other measures have been *faithfully* tried and found wanting, every patient should be offered that measure of relief that surely can be gotten from abdominal section.

In the interest of conservatism, let us hope that this will not always mean extirpation of the tubes and ovaries, for who can say that the abdominal surgeon may not devise means by which those organs may be so treated as to secure health without always robbing of the possibilities of maternity. Some recent work of my own in that direction encourages me to think that this may yet be an accomplished fact.

Conclusions: Salpingitis is not a new disease, nor a rare disease. It is, with peritonitis, the most common form of inflammation about the uterus, holding in point of frequency about the same relation to the extra-uterine surface that endometritis does to the intra-uterine. The majority of the cases get well. A minority do not, and these are capable of causing such danger and distress that abdominal section, with removal of the tubes and ovaries, becomes a necessity.

THE RADICAL TREATMENT OF VARICOCELE.

By E. L. KEYES, M.D.,

NEW YORK.

In The Medical Record of February 20, 1886, I published a short article upon the treatment of varicocele, advocating the subcutaneous application of catgut.

During March and April, while in England, I was impressed by the impunity with which Mr. Lawson Tait seemed to use silk for all purposes. He assured me that he was in the habit of having his ligatures at the bottom of ordinary wounds disappear without giving him any trouble. I can only vouch for this statement, not for the fact, since I had no opportunity of observing it. Mr. Tait seems to prepare his silk in simple hot water.

I determined to try silk in varicocele. On my return to this city in April, I operated, for the first time with ordinary twisted surgeon's silk, rather fine. I prepared, it by boiling in simple water, and carried it to the hospital in a bottle full of alcohol and bichloride of mercury, one in one thousand.

The case was a very bad one, the veins large, the tissues lax and pendulous, the patient anæmic and feeble. I operated as already detailed in The Medical Record, February 20th. My patient had not a bad symptom, got up at the end of the fifth day, and left the hospital on the sixth day. I have seen him recently, three months after the operation. A solid cord replaces the site of the former wormy bunch of veins. The veins are patulous below, but shrunken, and the patient has lost the discomfort and dragging pains formerly complained of.

I have operated since the middle of April upon five cases with silk, my house surgeon at Bellevue, Dr. Mitchell, upon two. My patients remain in bed five days, and always leave the hospital at the end of the week. No dressing is made, the testicle being simply supported upon a piece of rubber plaster passed across the thighs beneath the scrotum. Sometimes an anodyne for a couple of days is required, sometimes a laxative. I have never used an anæsthetic, except sometimes a local injection of cocaine hydrochlorate at the time of operating. I have never seen a bad symptom, never a drop of pus. Whether the silk is absorbed or not I do not know; certainly the small, hard lump remains about the cord more than three months, gradually growing smaller, and painless.

One strong incentive which caused me to experiment with silk was a letter from a physician, one of my catgut operations, received in April, which informed me that he feared that the vein tied with catgut had in his case again become pervious. I think this may perhaps occur in some cases after catgut, but believe it impossible if silk is used.

I have modified my needle, the one I now use being figured herewith. The front eye carries the ligature; the loop of silk passes through the other eye and is held tense over one of the steel buttons in the handle of the needle.

I see in Bell's article in the "International Encyclopædia of Surgery," vol. vi., p. 589, which appeared in June of the present year, that Mr. Barker[1] has used silk antiseptically applied through a puncture made by a knife. The silk is cut short and left in. He dresses with salicylated wool and reports that his patients have no suppuration and leave the hospital in "ten days or a fortnight." This method seems less good and less speedy than the subcutaneous application of silk by the aid of a needle.

How long silk has been used subcutaneously and by whom it was first employed in this manner for the cure of varicocele, I cannot say. It is quite possible that the practice is very ancient, but I had not heard of it when I began to use silk.

That it has been so used since January, 1878, is proved by a short article[2] in the August number (1886) of the *Annals of Surgery*, from the pen of Mr. Ogston, of Aberdeen. I received this journal to-day, August 9th. He uses carbolized silk, dresses for three days with salicylic wool, and says that "at the end of three weeks the patient can safely walk about, using, however, a suspensory bandage, and being careful to avoid strain, pressure, or fatigue of the part."

TREATMENT OF INEBRIETY.

By C. F. BARBER, M.D.

FORT HAMILTON, L. I.,

In reviewing the subject of my heading, I am struck with the fact that there seems to be a want of harmony existing between the many authorities writing upon it. Some seem to be in doubt as to the way in which this disease should be handled, while others mark out for us an explicit course to follow. Bearing these facts in mind, I deem it not presuming on my part to place before the readers of The Medical Record the course pursued in an institution where hundreds of addicted persons are treated yearly.

In the first place, it is with much reluctance that a patient will consent to enter an institution, nor, in many cases, will the friends of the patient take the steps to have the unfortunate victim placed where care and proper restraint can be exercised. It is then, I may say, with the inebriate proper we have to deal. It may be an old, steady drinker, or one who at intervals—at first months apart, now but a few days, or at longest a week or two—indulges in his uncontrollable dissipation.

I am sorry to say that in this country the amount of liquor consumed is surprisingly great, and many inebriates exist where we least suppose such a condition possible. I feel safe in saying that the American of the present day cannot, as a rule, use liquor without overstepping the bounds of propriety.

Unquestionably, the first procedure with these patients is to place them in as advantageous a position as circum-

[1] Lancet, 1886.

[2] Page [illegible].

stances permit ; a place where restraint can be exercised, where their habits can be controlled, and where they may be supplied with the best dietary possible. Healthful sleep, regular meals, and abstinence from stimulating liquors are the great factors in restoring the shattered nervous system and failing bodily health.

When the physician is called, he does not find his patient in a state of sobriety, but suffering from the effects of a debauch ; eating little or nothing, but stimulating instead, nervous in the extreme, with head throbbing, perhaps having hallucinations, the stomach irritable and unable to retain food, insomnia pronounced. We are advised by many to cut off the supply of stimulants at once, and by administering nervines to control the excitement, and tone the system by tonics. Theoretically this may seem correct, but practically I am certain it is unsuccessful. We are taught never to empty an overdistended bladder rapidly, but to allow a little urine to flow at a time, thus permitting the overtaxed muscles to regain their normal state.

If this procedure be scientific, as we know it is, why not allow this overtaxed system to gradually drift back to the normal condition by allowing a moderate supply of stimulants? Place two cases side by side, and to one administer nervines, tonics, etc., to the other allow a guarded amount of liquor, and I am certain you will not hesitate to agree with me in adopting the latter course. Permitting these cases a supply of liquor will, and has prevented many attacks of delirium. I do not, nor can I, think anyone will deny the utility of the bromides, chloral, opium—the latter especially—in delirium, when other means have failed to produce sleep. As to the kind of liquor called for in these cases, it is difficult to lay any special rules. Whiskey, administered in milk with an egg, is probably the best means of aiding the patient to recovery. Beer and ale I have seen produce wonderfully good results when all other means have failed. There occur cases where chloral has a tendency to produce excitability, and the bromides have little or no action ; in such I have seen the fl. ext. piscidiæ erythrinæ and ex. hyosciami produce most excellent results. A purge will often relieve many disagreeable symptoms. To allay the irritability of the stomach we must keep the patient quiet, permit the free use of ice, but allow little water, cold water seeming to produce an increased desire to vomit. A glass of hot water will sometimes stop emesis. The usual sedatives may be given, but milk diluted with lime-water, and beef-tea or broths, given hot, are more liable to be retained than other forms of food.

So soon as the patient is able to retain solid food, stimulants may be lessened or abandoned. Tonics of quinia, gentian, nux vomica, or some of the preparations of iron, may be given with good results. We are asked as to the length of time a patient should remain in an institution. Experience, our best guide, has shown us the longer the abstinence the better the result. A good plan, which has been adopted by some with much experience, is to oblige a continuous residence of three months, after which the patient may be allowed to go and come at intervals, so long as he may continue to do well. Should he continue to be free from the use of stimulants for several months, it is fair to presume he is able to launch once more into the world. When injuries or diseases are the cause of an abnormal mental condition, we cannot hope for a good result until the cause is removed.

CAN A MAN HAVE A FEMALE COMPLAINT?—A young man entered the Dispensary of the Chicago Policlinic recently, and going up to the clerk held out one of the dispensary circulars, with the question : "Say ! isn't this the hour for diseases of women ?" The clerk answered in the affirmative, when the young man said : "Well ! I've got a disease of a woman and want to be treated." —*Journal of the American Medical Association.*

Clinical Department.

ON THE TREATMENT OF SUMMER DIARRHŒA OF INFANTS BY ANTIFERMENTS.

DR. DOUGLAS MORTON writes : "For several years my management of the summer diarrhœa of infants has been based upon the belief (1) that in cholera infantum there prevails vaso-motor paralysis identical in character with that of sunstroke ; (2) that this condition, involving more or less turgidity of the blood-vessels of the gastric and intestinal mucous membrane, and consequent abeyance or impairment of digestion, leads to fermentation of the ingested food ; and (3) that the inflammatory phenomena that frequently occur in the course of these diarrhœas are attributable to the irritant action of intestinal contents in a state of fermentation. It has been shown that inflammatory lesions increase in frequency and intensity as the sigmoid flexure is approached. Practically, in all cases, the lower part of the colon is the seat of lesion ; it occurs less often in the ileum, and is rare higher up. Bearing in mind that fermentative products increase in quantity and irritating qualities as the process advances and the intestinal contents are propelled in their course through the canal, these facts of pathology are just what would have been looked for.

"This simple view of the nature of the disease, in which the difference between the severest cholera infantum and the milder diarrhœas that occur in hot weather is regarded as merely one of degree, and in which entero-colitis is considered, at least in a great number of cases, a result of, or a stage in either manifestation, appears sufficient for the facts of the case. The assumption that has been made of a microbe of cholera infantum seems entirely unnecessary. The widely and densely diffused germs of the ordinary fermentations are taken in with the food, and, in default of an adequate supply of normal digestive ferments, they speedily begin their peculiar work of decomposition with the production of irritant matter enough to account for all local inflammation, and probably, through absorption, when this is possible, for general symptoms.

"In milder forms the dejecta are made up in large part of food in process of fermentation, and are consequently of acid reaction. In cholera infantum, on the other hand, the stools are alkaline, and this, doubtless, is due to the fact that the quantity of blood serum poured into the canal from the turgid vessels of its walls is sufficient not only to neutralize all acid present, but to give an excess of alkali. In these cases the osmotic relations seem to have been brought into a state of unstable equilibrium, and there remains only the irritant effect of undigested and fermented food to precipitate a profuse discharge.

"It appears, therefore, that there are two indications for treatment which lead all others in importance. The first is to overcome that effect of heat by which the mucous lining of the alimentary canal has been brought into a state of congestion and consequent readiness for great and rapid loss of appropriated material. This indication is to be met in the main by measures for reduction of temperature. The second indication is to prevent fermentation ; and since the question of diet has such important bearing on this point, I would like to impress the truth that food which fails to be digested not only adds nothing in the way of nutriment, but, by undergoing fermentation, becomes an irritant, and thereby causes a loss of already appropriated material. It therefore becomes sometimes an object of much importance in treatment to withhold food altogether for a considerable length of time.

"My purpose here is chiefly to emphasize the value in the treatment of this disease of agents that have the power of preventing fermentation. Until about three

years ago it had been my habit to use the milder antiferments in common use—as carbolic acid, hydrochloric acid, bismuth, chlorate of potassium, sulphite of sodium, and some others—and while using these I had never realized the importance of this part of treatment. Since that time I have been using two far more effective antiferments, nitrate of silver and bichloride of mercury, and have found that in many cases—perhaps the majority—to check and to prevent fermentation constitutes all the treatment needed. As to the comparative value of these agents I have not yet determined. My impression is, however, that when nausea and vomiting have been present the silver salt has given better results, but that generally the bichloride has been more useful. The dose that I ordinarily give of the former is gr. $\frac{1}{20}$ four or five times a day to a child one year old, dissolved in distilled water and largely diluted; and of the latter, gr. $\frac{1}{100}$, also dissolved in water to which has been added a little alcohol or aromatic tincture of some kind. There need be no fear that the bichloride given in doses amply sufficient to prevent fermentation will irritate the bowels, provided it be plentifully diluted with water.

"There may be diarrhœas in which it is well to give astringents, but I am quite sure they often do harm in the ordinary summer diarrhœa of children. Looseness of the bowels often continues for weeks after the acute stage passes off. In such cases I find an excellent remedy in the tincture of nux vomica, given in small doses—from a quarter to half a drop to a child a year old—every hour or two. This restores the lost tone of the arterioles throughout the alimentry canal, and greatly helps the enfeebled digestive powers. It is well at the same time to give pepsin with hydrochloric acid. There lies in one other drug, in considerable measure I believe, the power of counteracting the tendency in this disease to congestion of the abdominal viscera. This drug is belladonna. In cholera infantum I find it well sometimes to give hypodermatic injections of morphia, and give it associated with atropia in the tablet triturates so much used now. In the very minute quantity in which it is associated with the morphia in them, I find it sufficient to give decided color to the pallid face of a sick child, and, given alone in larger doses, I have seen it flush the face and neck with ruddy glow. In doing this it obviously draws a large amount of blood away from the internal organs."

A VEHICLE FOR QUININE, AND THE TREATMENT OF WHOOPING-COUGH.

Dr. F. A. Castle, of New York, sends us the following: "Dr. E. M. Lyon's recommendation of simple elixir as a vehicle for quinine (Medical Record, August 28th, p. 234) is open to the objection that the mixture of quinine salts with most sweet vehicles produces a worse-tasting compound than the quinine alone would be. The best vehicle for quinine is a solution of glycyrrhizin, and several formulas are in use among pharmacists for an elixir glycyrrhizæ comp. which serve to disguise the taste of quinine, as well as various other substances, much better than simple elixir. The glycyrrhizin seems to act by coating the crystals of the quinine salt, and for a few moments interfering with their solution. For this reason the elixir and the quinine should be prescribed separately, and their admixture be made just as they are about to be taken. A teaspoonful of the elixir, if well made, will disguise the taste of five grains of the sulphate of quinine quite perfectly, and nothing needs be taken afterward to remove any unpleasant taste.

"When quinine is taken in substance or in watery solution, and something is desired to dispel the bitter taste, I know of nothing better than a mouthful of soft bread. During service on a gun-boat in the Lower Mississippi I had abundant opportunities for trying a great variety of methods for administering quinine, and I never found anything equal in effectiveness or convenience to the chewing of a bit of bread-crumb. It seems to absorb the quinine and saliva from the surface of the tongue, and the impression upon the nerve-terminations lasts but a few moments after the morsel is swallowed.

"Respecting the treatment of whooping-cough by other methods, as referred to in the editorial article on p. 127 of The Medical Record for July 31st, I would like also to say that the value of cresylic alcohol (or cresol) is too little appreciated generally. By the aid of heat this substance is easily volatilized, and the air of a room may be sufficiently charged with the remedy to affect the respiratory passages. Since using cresol for this purpose I have rarely had occasion to resort to other measures, and nearly every case that I have treated with it improves rapidly as regards the severity of the paroxysms, the frequency of vomiting, the disturbance of sleep, and the amount of bronchitis. I have good reason for thinking that the duration of the disease is also somewhat shortened."

THE TREATMENT OF RHUS-POISONING.

Dr. R. G. Williams, of Whitney, Tex., writes: "While the subject of rhus-poisoning is under consideration, let me suggest a remedy which is certainly a specific, cheap, and found almost everywhere wherever the rhus grows. This remedy is more simple than bromine, does not cause any burning, stinging sensations such as are excited by the application of tinct. iron or spt. turpentine, and is more harmless than the corrosive sublimate. It is simply a strong decoction of the common cup-oak bark boiled to the consistency of tar, and applied by means of a camel's-hair brush or an ordinary brush or mop. It must be painted over the poisoned surface two or three times daily. Twenty-four hours' treatment is generally sufficient for a cure. This treatment is painless; the only unpleasant feature is the discoloration of the parts, but as this disappears in forty-eight hours it is really of no moment."

Dr. J. B. Kell, of Delphos, O., sends the following: "I desire to contribute my observations upon the treatment of this obstinate and exceeding painful cutaneous affection. I have been affected with the disease six times, the last attack occurring the past spring and being so severe as to render my features barely recognizable. As regards the treatment of my own cases, I have made use of many much-lauded applications, such as lead and opium wash, tincture of myrrh, and corrosive-sublimate solution, all of which certainly had a beneficial effect; but what I and the majority of sufferers have always desired is an immediate relief from the smarting pain and intense itching which are present. With me, none of the remedies I have made use of seemed to produce this anxiously hoped for relief, until I applied to the inflamed parts a saturated solution of potassium chlorate, the effect of which was extremely gratifying. The linen with which the remedy is applied need not be changed more than once an hour. In from twelve to fifteen hours the vesicles gradually disappear, the swollen part resumes its natural configuration, and life once more becomes enjoyable."

Dr. J. R. Flowers, of Columbus, O., writes: "I wish to add my mite to the therapeutics of ivy-poisoning. While camping out on Indian River, in North Michigan, during the summer of 1882, one of the ladies of our party was severely poisoned with ivy. An old native Indian gathered a quantity of boneset (*Eupatorium perfoliatum*) and, after pounding the tops and leaves to a pulp, applied it to the parts affected during the night. The next morning the swelling had all disappeared. Since that time I have used the fluid extract of the same for all my cases, and the result has been an immediate cure. Several of my medical friends have tried it, and the result has in every case been very satisfactory."

Dr. W. H. German, of Morgan Park, Ill., writes: "In the treatment of poisoning by Rhus venanata I have obtained better results from the use of the officinal gly-

cerite of tannin than from any other remedy. Applied freely every three or four hours it is promptly effective at any stage of the attack."

Dr. L. C. Winsor, of Spirit Lake, Ia., writes: "In an editorial published in the issue of July 31st, I see it stated that no internal treatment seems to be indicated in cases of dermatitis venenata. For a number of years past I have been subject, each summer, to attacks of that disease. When exposed to the rhus venenata I have found the numerous external applications to be of little benefit, except as palliatives. But during the last two years I have aborted several attacks in my own case, by the internal use of liq. potassi arsenitis, taken to produce its physiological effects. I have also had the same success in the cases I have had in practice. My experience, however, has been limited, and I desire to know if this remedy is reliable in this disease, or if my cases have all been of a very mild type."

TOY-PISTOL WOUNDS.

Dr. Robert T. Morris, of 945 Broadway, writes: "Dr. Powers writes on the above subject in The Medical Record for August 21st, and I should like to add a little testimony in support of his method of treatment. For a long time wounds made by blank cartridges gave me a good deal of trouble, and several of my cases developed cellulitis in the vicinity of the wound. When, after careful antiseptic dressing, one patient had tetanus and two or three had cellulitis, I decided to dissect out the whole region of the wound in my next case and find out if possible where the cause for the trouble lay. Shortly afterward a typical case came for treatment. There was the little dirty hole in the midst of a grimy palm, with just a suggestion of hemorrhage. The wound appeared to be quite superficial, and the probe would not enter the opening for more than one-eighth of an inch. Under strict antiseptic precautions I trimmed away the bruised skin and cut away a section of palmar fascia beneath, when, much to my surprise, a lot of felt wadding peeped up out of the hole. The wad, which had penetrated the palmar fascia as a small hard mass, had become swollen and infiltrated with blood until it would have filled a small thimble, and the elastic fascia had closed it in so completely that no one would have suspected its presence deep down in the hand. I opened the wound very freely and allowed it to granulate up from the bottom. Since that time I have treated a large number of blank-cartridge wounds of the palm, and have had no cases of wound-infection among them. Sometimes it was necessary to excise quite a large piece of palmar fascia in order to keep the wound open, and this was done in cases in which no wadding was found, because the minute grains of residue from burned powder often bruise the fascia and set up a low inflammation, which holds on in a discouraging way for weeks or months. The subject of blank-cartridge wounds is a very important one indeed, and principally because, as in sprains of the ankle, the injuries do not appear to require the radical treatment which is really necessary in order to insure recovery. The true character of the wound being recognized, the treatment is simple and effective."

ACUTE POISONING FROM SARDINES.

Dr. A. E. de Cailhol, of Los Angeles, Cal., referring to a case of poisoning from sardines reported in The Medical Record of August 7th, in which the writer asks whether the symptoms were caused by tin or ptomaines, reports the following case in answer to the question: "Ten years ago, when practising in St. Louis, Mo., I was called at night to treat a case similar to the one of 'M. C.' The symptoms clearly pointed to poisoning from copper. But there was no copper vessel in the kitchen. By very careful investigation and a great deal of talking with the mother, the only one of the family who was not ill, I obtained the following information: A week previous to the accident the father had had the fancy to eat sardines in oil; after having *completely detached the top* of the box and eaten two or three sardines, he ordered the remainder to be placed in the cupboard. On the evening I was called he asked for the sardines again, and the wife went for the box and placed it upon the table. The father divided the rest of the sardines between himself and his three children; the mother, in order that her children might have more, refrained from taking any. As she was the only one of the family not sick, of course I concluded that the sardines were the only cause of the trouble. *I asked* for the empty box and was told it was in the slop-barrel. I hastened to the back yard, and on the top of the barrel I found the tin box with some oil in it and the top with its label at the bottom of the box. My object was to analyze the remains; but, after examination at the light, owing to the oxidized condition of the copper label soldered on the loose tin top, I concluded that the case was one of copper poisoning. The copper label, having been in close contact with the oil and sardines for a week, had become covered with a coat of *vert de gris* which was perfectly visible on it, and, when soaked in oil and upon the sardines, had rendered the whole poisonous. I think the case of 'M. C.' had the same origin."

Progress of Medical Science.

Paresis of the Respiratory Muscles following Diphtheria.—Dr. Rothmann reports the case of a boy, seven years of age, who suffered from great difficulty of respiration following an attack of diphtheria six weeks previously. Inspection of the thorax showed the upper portion to be entirely without motion, and the lower ribs only rose and fell almost imperceptibly with the respiratory act. The epigastrium was also motionless, and none of the accessory muscles of respiration came to the aid of the little sufferer. The only way in which the child could increase his feeble expirations was by pressing with his little fists on the upper part of the abdomen. The treatment consisted in hypodermatic injections of strychnine, and the application of the induced current to the phrenic nerves and the abdominal muscles. After twenty applications of electricity, and the administration of about one-third of a grain of strychnine the patient was cured.—*Wiener Medizinische Wochenschrift*, June 12, 1886.

Immediate Restoration of Parts to the Normal Position after Tenotomy.—The following are the conclusions of a paper read by Dr. Reginald H. Sayre at a meeting of the Orthopædic Section of the Academy of Medicine (*Alabama Medical and Surgical Journal*, July, 1886): 1. After tenotomy the parts should be immediately restored as nearly as possible to the normal position, and there retained during ten days or two weeks, after which time whatever subsequent treatment may be necessary to vitalize paralyzed muscles, or complete the restoration of natural functions, should be carried out as may be necessary. 2. This proceeding is accompanied by the least discomfort to the patient, and annoyance to the surgeon, and with a vast saving of time. 3. There is no more danger of non-union of the ends of the divided tendon in this manner than by other modes of proceeding. 4. There is less apt to be a thin, imperfect bond of union between the ends of the tendon than when the gradual reduction of the deformity is practised. 5. This mode of operation is applicable at the foot, knee, thigh, or neck, where there is no anchylosis to be overcome, but that in cases of long-standing anchylosis at the knee when tenotomy is but preparatory to *brisement forcé*, the latter should be deferred for forty-eight hours, to avoid possible risk from gaping of the external wound due to the

violence of the manipulations. Should the deformity at the knee be due simply to contractured muscles, immediate replacement may be practised here also.

Hyperæmia and Phlegmon of the Vagina.—Dr. Antonio Stravino reports several cases of this condition, occurring in consequence of sexual abuses (*Giornale Italiano delle Malattie Veneree e della Pelle*, May and June, 1886). Among the causes he distinguishes the exciting and the predisposing. Of the former he mentions frequent repetition of the sexual act, its performance during menstruation, or too soon after child-birth, masturbation, gonorrhœa, and the use of cold to suppress the menstrual flow, or leucorrhœa. Of the predisposing causes the most potent are the great vascularity of the uterus and its adnexa, the numerous anastomoses, and the serpiginous course of the vessels tending to retard the circulation, the complicated venous circulation, the abundance of lymphatics, and the free communication existing between the subperitoneal and uterine lymphatic ducts. Besides the usual symptoms of vaginal phlegmons, there are acute pains during coitus, a tendency to menorrhagia and metrorrhagia, and to leucorrhœa, sterility from the acidity of the uterine mucus, gastric disturbance, and nervous irritability. In the treatment, Dr. Stravino recommends absolute rest in the supine position with the legs elevated, abstention from the sexual act, the application of cold, local abstraction of blood, and a general tonic regimen.

Excision of the Primary Sore in the Prevention of Syphilis.—Dr. Andronico reports four cases in which he excised the initial lesion of syphilis, with a result of preventing the appearance of secondary symptoms. All the cases were apparently above suspicion, as the author was able to trace the source of infection and to convince himself of the nature of the affection in each instance. He concludes from these cases that: 1. The abortive method is an effectual means of preventing systemic infection, when the primary lesion is situated upon certain parts suitable for operation, such as the labia majora or minora, prepuce, or skin of the penis, etc. 2. The excision must be made within forty-eight hours, or, at most, within three days after the appearance of the chancre. 3. A greater age of the primary sore and the existence of glandular infection are contra-indications to the operation.—*Giornale Italiano delle Malattie Veneree e della Pelle*, May and June, 1886.

Nervous Eczema.—Dr. Tommasoli relates the following interesting case. (*Giornale Italiano delle Malattie Veneree e della Pelle*, May and June, 1886). The patient was a boy six years of age, who had had for eighteen months symmetrical patches of eczema on the legs, forearms, and ears. Various methods of treatment had brought about some amelioration, but not a cure, which was obtained only by prolonged use of the sodic chloride of gold. The boy was of an irascible disposition, and had intervals of aggravated bad temper which, his mother said, rendered him unbearable to those about him. During these attacks, although every precaution was taken to prevent him scratching himself, there was an increase in the areas of eczema, and the patches, which were usually dry, became moist and covered with crusts, and there was an increase in the number and size of the papules.

Treatment of Ulcers by Carbolic Acid Spray.—M. Gilles de la Tourette reports in the *Revue de Chirurgie* for July, 1886, several cases of indolent varicose ulcers, which had resisted all other ordinary methods of treatment, cured by the use of a spray of carbolic acid. The solution used varied in strength, according to the apparent indolence of the ulcers, from 1 to 50 to 1 to 20, and the ulcer was sprayed continuously for from an hour and a half to two hours every morning and night. In the intervals the surface was covered with borated vaseline of ten-per cent. strength. From the very first days of treatment the pain grew less, and soon disappeared. There were no symptoms, either local or general, of phenic-acid poisoning. Extreme age and debility of the patients offered no contra-indication to the treatment. The author found that the best results were obtained in ulcers with flat edges from which cicatrization could readily proceed, and he was unsuccessful in those cases with hard and elevated edges. After the treatment had been carried out for some time in such cases, the surface of the ulcer would look healthy but the edges still remained indurated. It was proposed to scarify the edges but the patients would not consent.

Anæsthesia [illegible] Dr. Pitres relates in the *Journal de Médicine de Bordeaux*, a case which well illustrates the power of hypnotic suggestion in producing anæsthesia. The patient was an hysterical woman, easily hypnotizable, who was suffering from a very painful phlegmon on the left thigh, following a hypodermic injection. The abscess was the seat of acute shooting pains, and could not be touched without causing the patient to scream. Dr. Pitres proposed to put the woman to sleep by hypnotism, then to order her to allow the abscess to be opened without feeling any pain, either during or after the operation, and finally to wake her up and make the incision. This was done as proposed; a dissection was made down upon the abscess, which was emptied of the pus, cleaned and dressed. During all this time the patient watched the proceedings with a smile, and expressed astonishment that the abscess could be opened without giving her the slightest discomfort.

Treatment of Glaucoma by Cocaine and Eserine.—Dr. H. Armaignac reports in the *Revue Clinique d'Oculistique* for June, 1886, two cases of glaucoma treated by instillations of cocaine and eserine. The former was used in a three-per cent. solution, the latter in a solution of the strength of 1 to 200. A drop of each was placed in the eye at intervals, varying according to the indications, and six minutes were always allowed to elapse after one solution was instilled before the drop of the second solution was put in the eye. Very signal benefit was obtained in each case, and the writer hoped that the success obtained would lead to further trials of this method of treatment.

Cæsarian Section in Country Practice.—Mr. Thompson Forster relates in *The Lancet*, of August 14, 1886, an interesting case of Cæsarian section successfully performed under great difficulties. The case was one of dystocia from contracted pelvis, and the woman had been in labor two days. The head was perforated and every effort made to extract it, but without success. It was then determined to perform the Cæsarian section. The woman was laid across the bed, the nurse took charge of the patient's hands, and an assistant gave the chloroform. A farthing candle was on the bed, another on a chair with a basin of water and some sponges, and one small oil-lamp was on a box with the instruments. No more assistants could be had, as the room was not large enough to accommodate them. The incision was made through the abdominal wall and the uterus, and the child was abstracted. Considerable hemorrhage occurred, but after some difficulty the uterus was made to contract and the bleeding ceased. During the whole of the time the woman was vomiting violently, and the intestines escaped from the wound. These had to be held back with one hand while the sutures were passed through the abdominal wall with the other. Of course, no attempt at antisepsis was made. There was considerable elevation of temperature during the succeeding days, and trouble was experienced from bed-sores, but the woman eventually recovered, and one month after the operation was met by Mr. Forster, walking with her husband.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, September 18, 1886.

CALOMEL AS A DIURETIC IN HEART DISEASE.

IN the eager search after, and trial of, new remedies which seem to characterize the modern school of therapeutists, and for the furtherance of which even several medical journals have been specially established, we are in not a little danger of overlooking valuable properties possessed by some of the standard agents of the materia medica. It is seldom that one can open a journal of the present day without seeing a notice of some new hypnotic, antipyretic, cardiac stimulant, or anæsthetic, but the study of the older remedies, the catalogue of whose virtues is by no means complete, is apparently well-nigh abandoned.

Dr. B. Stiller, of Buda-Pest, contributes an article to the *Wiener Medizinische Wochenschrift* of July 10, 1886, upon the curative properties of calomel in cardiac dropsy. While recognizing, that digitalis, properly employed, is the best remedy of the kind which we possess, he was yet not blind to the fact that it possesses some disadvantages, and set about to determine what other medicine was the best suited for use in the necessary intervals of the administration of foxglove. Convallaria, maialis, adonis vernalis, and caffein, were each in turn tried, and rejected as unsatisfactory. Finally he saw in the *Orvosi Hetilap* a report by Dr. Jendrassik of a number of cases of cardiac dropsy successfully treated by calomel. The latter had accidentally discovered the diuretic action of calomel while giving it, for another purpose, to a patient with heart disease.

Acting upon the suggestion of the Hungarian journal, Dr. Stiller began experimenting with the mercurial. The results obtained were so prompt and convincing that the writer is led to rank the drug among the most valuable of all cardiac diuretics. In the case of a man, sixty-eight years of age, with ascites and œdema of the lower extremities dependent upon mitral insufficiency, the secretion of urine was increased within a week from thirty to over one hundred ounces a day, and in another week the dropsy had entirely disappeared. No other remedy than calomel was used. In another case of ascites and anasarca, following general dilatation (weakened heart), the quantity of urine was increased in five days from a little over ten ounces to over one hundred. A number of other cases are reported in which equally striking results were obtained.

From a study of all the cases thus treated the author comes to the following conclusions: 1. Calomel is a prompt diuretic and hydragogue in cardiac dropsy, its action in this respect being even more speedy and intense than is that of digitalis. 2. It removes not only œdema of the tissues, but also effusions within the great cavities of the body. 3. Diuresis usually comes on suddenly on the third or fourth day; it is then advisable to discontinue the remedy, and to resume it only in case the urine becomes again markedly reduced in amount. 4. Calomel seems merely to facilitate resorption of the fluid, and not to exert any influence upon the heart or kidneys; yet œdema, consequent upon nephritis or obstruction to the portal system, and inflammatory exudations, do not appear to be influenced favorably by the mercurial, and even in cardiac dropsy, when the urine is very albuminous, the action of the calomel seems to be retarded, no effect being observed in many cases until the fifth or sixth day. 5. Finally, the drug is no substitute for digitalis, since it is not in any sense a cardiac remedy; but it answers an admirable purpose as a complement to the other, and as a special stimulant to resorption in cases of necessity.

The dose employed was usually about three grains three times a day, though sometimes smaller quantities more frequently repeated were found more beneficial. Diarrhœa was a frequent result, and sometimes necessitated the temporary withholding of the remedy; but it could be restrained by opium, which latter, given in combination with the calomel, seemed not to affect its diuretic action. The writer met with but one case of stomatitis, although Jendrassik found it to occur with rather unpleasant frequency.

THE FUNCTION OF THE PROSTATE GLAND.

PHYSIOLOGISTS have for a long time believed that the prostatic secretion served some more important purpose than that merely of a diluent of the spermatic fluid, but they were unable to determine precisely what its other functions might be. As is known, the secretion is a thin milky fluid, of an acid reaction, and containing various salts formed by the union of phosphoric, sulphuric, and hydrochloric acids with potassium, sodium, and calcium. It also contains a peculiar organic base, the phosphate of which, known as Böttscher's spermatic crystals, gives to the seminal fluid its peculiar odor. The milky appearance is due to an emulsion in an albuminous fluid of five drops of lecithin.

That the prostate gland plays an important part in the generative function is shown by the fact that it exists only in the male, and that it remains undeveloped up to the time of puberty. Experiments have shown also that the prostatic secretion is a stimulant to the spermatozoa, and as it is an integral part of the ejaculated seminal fluid, Buxmann believed that its most important function was to preserve the life of the spermatozoa. This theory has recently received confirmation through a case reported by Professor Fürbringer, at a meeting of the Berlin Medical Society (*Berliner Klinische Wochenschrift*, July 19, 1886).

The patient was a young man, thirty years of age, who was sent to the author on account of spermatorrhœa.

He was a moral and intelligent gentleman, of a nervous disposition, and with a neuropathic family history. Examination revealed no organic cause for his trouble, and the diagnosis was made of neurasthenia, with the added symptom of seminal losses during defecation and micturition. Examination of the fluid showed it to be odorless, Böttscher's crystals were absent, and though well-formed spermatozoa were present in great numbers, most of them were motionless, only a few executing sluggish movements for a minute or two. The emission was a simple flow of the unmixed contents of the seminal vesicles, due, without doubt, to a nervous atony of the ejaculatory ducts. The patient was sent for treatment to an institution for nervous diseases, and returned after two months very greatly improved in health, suffering from passive seminal losses only at rare intervals. A second examination of the fluid gave the same results as the previous one. But he shortly afterward had an emission, accompanied by erection, during sleep, and an examination of this matter showed it to be a perfectly normal seminal fluid. Well-formed Böttscher's crystals were present, and the movements of the spermatozoa were visible for over twenty-four hours.

From a study of this case the author concludes, justly as it would seem, that the function of the prostatic secretion is to exert a specific vivifying influence upon the spermatozoa, which while in the seminal ducts and vesicles possess but slight vitality, quickly die when removed from the body unless subjected to the stimulating influence of the prostatic fluid. Thus Buxmann's supposition appears to be confirmed, and a not unimportant advance has been made in the study of the physiology of generation.

THE UTILITY OF OPERATION IN EPITHELIOMA OF THE LIP.

It is commonly supposed that epithelioma of the lip is one of the most curable of all forms of cancer, and that its removal by excision is less frequently followed by a return of the disease than is that of any other variety of malignant growth. Yet writers on this subject are by no means agreed as to the prognosis in such cases, some alleging that an early operation is almost invariably successful, while others, although admitting that a removal of the neoplasm prolongs life, believe that a return occurs in nearly every instance.

We find in the *Centralblatt für Chirurgie* of June 19, 1886, an interesting series of statistics bearing upon this point, collected by Dr. A. Wörner from the records of the clinic at Tübingen and from other sources. The number of Tübingen cases was 305; and of these, 354 operations were performed upon 277 patients. In the greater number the removal was accomplished by a simple V-shaped or semicircular incision, though in a few, owing to the extent of the disease, resection of a portion of the jaw was required. Of the 277 patients operated upon, 142 relapses occurred in 111 individuals, of which 87.3 per cent. occurred within the first year and 12.7 per cent. after the lapse of one or more years. In one instance the disease returned nine years after the operation; the growth was removed a second time, and then the patient passed eleven years without a relapse, and died finally of old age. Of the 277 cases, [illegible]; per cent., were still living, without a return of the disease, at an average period of 5.8 years after excision, and 71, or 25.63 per cent., had died of other affections at an average period of freedom from relapse of 8.4 years after operation. The mortality of the operation itself amounted to 5.77 per cent., the fatal termination in most cases being attributable to hypostatic pneumonia occurring in individuals of advanced age. The greater number of the operations was performed prior to the introduction of the modern antiseptic methods.

Dr. Wörner has also collected another series of cases from the writings of Thiersch, v. Bergmann, Billroth, Winiwarter, Fischer, Kocher, and Partsch. Of the 866 cases in this series, 244, or over 28 per cent., were free from a return of the disease after a period of three years following excision, and of the 622 relapses, 545, or 87.6 per cent., took place within the first year. The mortality following the operation was for the entire series about 7 per cent., varying, in the statistics of the different operators, from 2.81 to 14.9 per cent. The cases all belonged to the pre-antiseptic period.

From these two series of statistics, embracing in all 1,143 cases, we find that a very large proportion of all cases of relapse occur within the first year, while the number of relapses after the third year is so small that patients who have survived this period without a return of the disease may, almost with certainty, be regarded as definitely cured. But, what is of greater importance and more to the point, these figures establish beyond question the value of excision of the growth, and justify the general opinion that operation is beneficial and necessary in epithelioma of the lip. Of the Tübingen cases over 57 per cent. lived for three years or more without a return of the disease, and of the cases reported by other observers 28 per cent. were free from relapse at the expiration of the same period. Thus, roughly speaking, we are justified in hoping that from one-fourth to one-half of our patients will be permanently cured by an operation; and for the others, unless the disease be so far advanced as to be beyond the reach of the knife or the caustic, we may at least expect a prolongation of life and a considerable period of freedom from suffering.

CONDURANGO IN GASTRIC TROUBLES.

After the disappointment of some sanguine therapeutists whose hopes had been raised by reports of the alleged virtues of condurango as a specific for cancer, the drug fell into disuse and almost oblivion. But if the experience of Dr. Wilhelmy, of Berlin, be borne out by others, we may expect to see a rehabilitation of it as a remedy of some value in certain affections, though not in carcinoma.

This author writes in the *Berliner Klinische Wochenschrift* of July 19, 1886, that he has found condurango wine very serviceable in many affections of the stomach. He was led to use it from the fact that Friedreich had claimed to have cured carcinoma of the stomach by condurango; and while believing that there had been an error in diagnosis, he yet thought it likely that the drug would prove to be of value in non-cancerous gastric diseases. He prepared a wine of ten per cent. strength, made from good Madeira, to which was added two per

cent. of citrate of iron, and a bitter to disguise the taste. In cancer of the stomach he found that the wine without iron, given in two tablespoonful doses four times a day, reduced the pains very considerably within two weeks, increased the appetite, and quieted very markedly the distressing vomiting. The cancer was not cured, for the patients died, but their life, while it continued, was made much more endurable. In cases of cancer of the pylorus, he found that a longer continued moistening of the surface of the neoplasm was of service, and to this end advises the exhibition of somewhat larger doses, about three tablespoonfuls.

Much more distinct, and in some cases even brilliant, results were obtained in the treatment of gastric ulcer by condurango wine with iron. The best results were observed in those instances in which chlorosis appeared to be the cause of the ulceration. Only those cases are cited in which vomiting of blood, the passage of blood in the stools, or the presence of a fixed circumscribed painful point over the region of the stomach, rendered the diagnosis certain. The author gave the ferrated wine in tablespoonful doses six times a day, whether hemorrhage were present or not, and had almost always the satisfaction of noting the disappearance of bleeding and of pain within from two to four days. He used morphine and ice only in a few of the worst cases, but of course observed great care in the regulation of the diet. Many of the patients were domestic servants, and they were usually able to return to their duties within eight or ten days, though the use of the wine was continued for two months longer. There were a few relapses, but they were not severe, and were of very short duration. The chlorosis was cured as well as the ulceration. In other chronic affections of the stomach good results were obtained, and Dr. Wilhelmy says that he was especially pleased with the effects in phthisical anorexia. The exhibition of the wine in these cases was quickly followed by a very noticeable and lasting improvement in the appetite and digestion.

CONTRAST BETWEEN AMERICAN AND BRITISH METHODS IN LAMP OPERATION FOR HEMORRHOIDS.

Almost simultaneously an American writer and a British writer described the methods of removing hæmorrhoids with the clamp and cautery, together with the after-treatment. The contrast to the description of the latter is interesting and instructive.

Dr. Richard Davy, in a clinical lecture on rectal fistula and hæmorrhoids at the Westminster Hospital, says, in closing his account of the operation: "After all the hæmorrhoids have been carefully removed, inject about one ounce of sweet oil into the rectum; and should oozing be free plug the rectum." This he does by the means of a sponge covered with oil-silk introduced with a pair of bone forceps. Then he goes on to say: "The after-treatment consists in good, nutritious, non-stimulating diet, rest in bed, the moderate use of opium, and retention of fæces, so as to avoid the action of that complicated group of muscles necessary for the act. I have often had my patients pass two, or even three, weeks without any action of the bowels; and although to the general patient this confinement seems very dreadful, any evil effect can be readily overcome eventually by a warm soap and water wash. The sponge is usually expelled or withdrawn on the succeeding or second day, and recovery is complete in about one month from the day of the operation."

Dr. C. B. Kelsey says in his paper on "The Treatment of Hæmorrhoids," in a recent number of The Medical Record, that after the clamp operation, "Seldom is it necessary to give any morphine except the suppository placed in the rectum immediately after the operation. . . . Very exceptionally does this method keep the patient confined to his bed and room after the tenth day . . . The bowels should not be confined more than fifty-six hours. If the bowels are confined until the tenth day great pain will be the invariable result of the first motion. The fæces have become hard and voluminous. Great straining and suffering are the necessary consequences. Moreover, nothing is gained. The wounds heal no more quickly for the constipation, if as quickly, and the idea that the passages may in some way cause them harm is not founded on fact.

"By the other plan an easy, natural movement is secured on the third day, which is attended with little or no pain. The rectum is thoroughly cleansed, not only of fæces but of blood and discharges, in the most natural and effectual way; there is less danger of absorption of offensive matter, and the patient, if one of regular habits, feels much better every way. After the first motion a gentle laxative should be given every night, for ten days longer, to secure one easy, natural passage daily.

"After the operation the patient may usually consult his or her own appetite as regards diet. Nothing reasonable need be denied—another point gained by getting the bowels in regular working order."

DISCOVERY OF THE PATHOGENIC ORGANISM OF THE SWINE-PLAGUE.

The extreme difficulties of reaching certainty in bacteriological researches must be apparent to anyone who has followed the record of its work in the past ten years. An excellent illustration is found in the study which has been made of the virus of hog-cholera (swine-plague, infectious pneumo-enteritis). Dr. D. E. Salmon gives some account of this in a recent issue of *The Sanitarian*. Hog-cholera costs this country some twenty-five millions of dollars yearly, and hence deserves attention from economists as well as men of science. It is an infectious disease spreading epidemically through herds. In 1876 Dr. E. Klein described a micrococcus which he found in the tissues of animals suffering from the disease. In 1878 he found, cultivated, and inoculated a bacillus, and thought it pathogenic. Lately, however, he has attributed the disease to a different bacillus occurring in the form of short rods. In 1880 Dr. Salmon found and cultivated a micrococcus which he believed, until lately, to be the essential virus of swine-plague. In 1883 M. Pasteur announced that the *rouget* of France, believed to be identical with our swine-plague, was caused by a dumb-bell-shaped microbion. This germ, he said, could be attenuated and made to act as a vaccine. We are told, however, by Dr. Salmon, that the vaccine which Pasteur now sells for *rouget* contains a fine bacillus,

which grows in cultures into filaments of considerable length. Inoculations with this vaccine, according to Dr. Salmon, do not cause a disease identical with [illegible] plague.

Dr. Salmon states that he has at last found a [illegible] which seems to be very certainly the cause of swine-plague. The organism is rather a bacterium than bacillus; it is very irritant, and produces all the symptoms and lesions of the disease. It was found in the tissues of hogs in the early stage of the disease, and it is believed that previous errors have been due to the fact that in the late stages various septic and other organisms develop.

DO LOWER ANIMALS HAVE TYPHOID FEVER?

For many years it was contended that the so-called pig-typhoid, or, as it is now known, infectious pneumo-enteritis, was identical with human typhoid. French veterinarians have also claimed that horses suffered from typhoid fever; but the swine-plague has been found to be a distinct disorder, and the question whether the horse can have typhoid is still unsettled.

Recently, however, Dr. J. Bland Sutton (*Journal of Comparative Medicine*) brings forward evidence to show that monkeys, tigers, and beavers may have enteric fever.

In 1839 M. Rayer describes an epidemic of this disease which broke out among the monkeys in the ménagerie of the Muséum d'Histoire Naturelle, Paris. On this occasion, M. Serres, who had previously observed the affection in monkeys, dogs, and cats, and had made careful preparations of the intestinal lesions, was able to make careful observations on the animals during life. The symptoms were very striking, being diarrhœa, increased frequency of pulse, and fever ending almost always in death.

Dr. Bland describes cases of typhoid fever which he observed, in 1882, among the monkeys of the London Zoological Gardens. While making a post-mortem examination on a lemur which had died in the Zoological Gardens, from perforation of the ileum near the cæcum, the Peyer's patches were found to be ulcerated in the same manner, and presented the typical appearance as these structures do under the same condition in man. No other organs presented lesions of note. For some days before death the lemur had suffered from profuse diarrhœa, the keeper experiencing considerable difficulty in keeping the cage clean. Dr. Bland was so positive that the ulcerations were typhoid that the deaths of other monkeys were predicted.

Seven days later another monkey, which had lived in the cage with the first, died with the same symptoms and lesions; later, two other monkeys and a tiger died of the same disease. At the time these cases occurred typhoid fever was raging in the neighboring district.

In 1885 the Zoological Gardens received an instalment of six Canadian beavers. Four of these died with a disease lasting about six weeks, and characterized by disinclination to food and profuse diarrhœa. On post-mortem examination ulcerations of Peyer's patches were discovered.

Dr. W. L. Conklin, Superintendent of Central Park Menagerie, reports a case of apparent typhoid occurring recently in a monkey. The animal had suffered from diarrhœa and hemorrhages from the bowels, and an autopsy showed extensive ulcerations of Peyer's patches. Dr. Bland states that the utmost care was taken to exclude the question of tuberculosis.

Experiments with cultures of the typhoid bacillus have, it is believed, resulted in producing a disease allied to, or identical with, typhoid in the rabbit and guinea-pig, although here experimenters differ.

There is, however, more or less evidence that typhoid fever can affect, not only man, but the quadrumane—the tiger, cat, and dog, the guinea-pig and rabbit, and possibly the horse.

The importance of this fact, if established, is twofold: It makes it possible to study the disease more systematically, and to apply to it experimental methods; again, if our menageries and our stables can breed the typhoid poison, it is a matter of the highest importance that this should be known.

THE MUSCULAR DISEASE.

Under the above title a writer in the *Philadelphia Medical Times* describes the different forms of progressive muscular atrophy which originate and are confined to the muscle itself. The researches of neurologists in late years have clearly established the fact that there are two sharply distinguished forms of progressive muscular atrophy; the one has its seat in the trophic centres of the spinal cord, and it constitutes the ordinary type of progressive muscular atrophy. It is sometimes spoken of as the Duchenne-Aran form of the disease, and it is not infrequently met with by practitioners.

The other types include all the various forms of progressive atrophy in which the disease is seated primarily in the muscle; these are united by the writer under the general title of "the muscular disease." Up to within a recent period, observers had been describing and classifying as distinct disorders many different phases of this affection. For example, the pseudo-hypertrophy of children has been treated of as an independent disease; so also the infantile progressive muscular atrophy described by Duchenne, and the juvenile progressive muscular atrophy of Erb. Other forms were described and distinguished by the parts of the body first attacked, or the age of onset, or the presence or absence of a false or true hypertrophy. It seems quite evident now, however, that these atrophies are all essentially identical. They are family or hereditary diseases; they begin in the muscle, producing a degenerative atrophy of that tissue, with or without a false hypertrophy; their course is very chronic, and often interrupted by long periods of rest; the muscles are attacked one after another in the order of their anatomical relations, and not in groups having the same physiological function, as is the case in the spinal form of the disease. There are no vaso-motor symptoms and no fibrillary twitchings. All these things serve to separate the spinal and myopathic atrophies quite sharply, and also to unite the latter in a common type.

Few cases of the muscular disease have been recognized in this country, and these have generally been cases of pseudo-hypertrophy. It may be that a wider

knowledge of its characteristics will lead to the report of more cases.

The relations of the atrophies are well shown in the following table:

The progressive muscular atrophies of spinal origin	Aran) Bulbar paralysis. of Vulpian.
The primary progres	1. Pseudo-hypertrophic paralysis. (*a*) Juvenile atrophy of Erb. atrophy of Duchenne. (*c*) The non-atrophic form of Charcot. (*d*) Other types, classified (by Eich- attacked.

News of the Week.

The Case of Counter-prescribing and the Verdict.—Mr. W. A. Purrington, counsel for the Medical Society of the County of New York, sends us the following: "Sir: My attention has been called to an editorial in The Medical Record upon counter-prescribing, in which reference was made to a brief of mine in a recent case affecting apothecaries. I do not think that the discharge of the defendants in that case is attributable to any defect in the law—defective as our present law is. The question was one of veracity, and the committing magistrate believed the testimony, it would seem, of the defendants. Believing their testimony, he did right in discharging them; if he had believed the patient's story he should have held them. No reason was assigned for his decision; but I do not think there is any doubt but what, if anyone should do as the complainant testified the defendants did, a clear case of practice of surgery would be made out. They, however, flatly contradicted the patient, and the magistrate necessarily had to believe one side or the other; and I am perfectly satisfied with his decision."

A Fellowship in Pathology at the Johns Hopkins University, yielding five hundred dollars in addition to free tuition, will be granted in October, 1886, if a suitable candidate applies. The application must be made prior to October 1st. The candidate must give evidence of a liberal education (including especially physics, chemistry, biology, and modern languages), and of special aptitude for pathological study, such as that afforded by some previous scientific work. The holder of the fellowship will be expected to devote his time to some special line of investigation (not strictly professional) under the direction of the Professor of Pathology. Further information concerning the purposes and the regulations of University fellowships is contained in the "Annual Register."

The Medical College of the State of South Carolina in Ruins.—The following letter to Dr. L. A. Sayre, of this city, will explain itself: "Charleston, S. C., September 11, 1886. Dear Doctor: In the great calamity which has befallen the people of this city, the Medical College of the State of South Carolina has been seriously injured—to such an extent that the Faculty have felt constrained to appeal to members of the profession to aid them in repairing the damages. I have been requested by the Faculty to write to you, asking that you will use your influence among friends to obtain any assistance in their power. We hope to begin lectures on October 15th, perhaps in a temporary building. The entire roof of the college will have to be reconstructed; the walls also parted. The contributions to the people here have been very generous, but medical institutions and physicians derive no benefit from such. You know what peculiar position in a community we occupy: every service expected of us, and the most unselfish devotion to relieving others; while we are supposed to be endowed with the faculty of living on air. I need not give you any description of the scenes through which we have passed—the character of which has not been exaggerated in the papers—as these last have furnished the entire country with full particulars. We are still sleeping in a tent in a garden, as women and children complicate the difficulty, and are not readily moved out of the house in case of a shock. These have greatly subsided in force and frequency, and confidence is being fast restored. My house, being of brick, is seriously injured, but habitable. I remain, dear doctor, with best wishes for your health, sincerely yours. F. Peyre Porcher, M.D., Professor in Medical College of the State of South Carolina."

Cases of Glanders and Farcy have of late been quite numerous in this city, and the Board of Health has undertaken to enforce vigorously the articles of the Sanitary Code, compelling a prompt notification of the presence of this malignant and dangerous disorder.

Association of German Naturalists and Physicians.—The fifty-ninth annual meeting of this association will be held in Berlin, from the 18th to the 24th of September. There are to be thirty sections. The official programme has been issued, and contains a long list of titles of papers on various subjects, medical and scientific, which are to be presented.

New Swedish Universities.—The establishment of two new universities in Sweden is contemplated. They are to be located at Stockholm and Gothenburg. The two now in existence are in Upsala and Lund.

Society of Russian Alienists.—The first congress of Russian alienists is to be held in Moscow, in December, on the occasion of the second congress of Russian physicians.

Female Medical Students in India.—There are at present fourteen female students in the Madras Medical College, four of whom are natives of India. Lady Dufferin has done much to promote the medical education of women in that country, and has secured good appointments for a number of female physicians in Calcutta and elsewhere.

The Fifth Annual Meeting of the Society of Italian Alienists will be held in Sienna, from September 19th to the 25th.

A Congress of Cremationists.—The German and Austrian Cremation Association will hold a congress at Gotha about the middle of September. A matter which will be specially considered is, how to overcome the opposition of the various governments who have hitherto declined to permit cremation.

THE CHLORODYNE HABIT.—The number of forms of dissipation is something almost incalculable. We constantly meet with reports of the arsenic habit, the chloral habit, the ether habit, and many others, and the *British Medical Journal* notes three cases of the chlorodyne habit. At the inquest on the body of a lady, aged sixty-two, of independent means, residing with two elder maiden sisters, it was stated in the course of the medical evidence, that all three of the sisters had been in the habit, for two or three years, of taking chlorodyne in large quantities, so much so, that their bodies had become emaciated, their mental condition affected, and the use of their limbs had become impaired. The body of the deceased did not weigh more than fifty pounds, and death was due to continued overdosing of chlorodyne. The jury returned a verdict of death from continued overdoses of chlorodyne.

A DEFECTION ON VACCINATION.—The British Medical Association has been invited, through the public press, by an anti-vaccinationist, to select a "champion" to discuss in public debate with another champion, appointed by the anti-vaccination societies of England, the merits of vaccination.

FASTING IN RUSSIA.—It is stated in the *Echo World* that the Holy Synod, in St. Petersburg, has decided that Russian soldiers in future must observe Lent in the most rigorous way. They will have to fast not only during the four "Great Lents" yearly, but also every Wednesday and Friday, and the six great days of prayer and repentance. This is the calculation: The Great Lent (of Easter), 79 days; Petroffki Lent, 20 to 50; Usspenski Lent, 17; Filippoffski Lent, 39; six days of prayer and repentance, 6; 31 Wednesdays and 31 Fridays, 62; total, 170 to 200 days, on which dates neither meat nor fish (during the Easter Lent), nor eggs, nor milk, nor even sugar, is allowed. The officers assert that the physical strength of the soldiers must inevitably suffer from the new regimen.

A NEW DANGER IN OVARIOTOMY.—The dangers of spaying have hitherto been confined to the woman operated upon, and, owing to the greater skill which has come from the rapidly increasing experience of many operators, these have been growing less and less. But now it is the operator who is incurring the greater risk. Two surgeons in Liverpool have recently exposed themselves to the vengeance of the irate husbands of their patients. One of these aggrieved individuals has sued a surgeon for damages for unsexing his wife, and the other has sent the author of his woes a challenge to fight a duel.

ANOTHER PROTEST AGAINST INDISCRIMINATE OVARIOTOMY.—It is evident that the medical conscience is beginning to be awakened to the fact that the operation of spaying is often performed without sufficient justification. In a recent article on "The So-called Laparotomy Epidemic" in the *Dublin Journal of Medical Science*, Dr. T. More Madden expresses himself in the following terms: "The facts cannot be eliminated from consideration in this discussion that the ovaries are to women what the testes are to men, and that by their complete removal in either case the mutilated individual is thereby unsexed. New [illegible] hence the more euphonious phrases by which the removal of the uterine appendages are now referred to, or the more scientific and successful method in which this is accomplished, do not render the ultimate consequences of operations for spaying, or castration of women, now less important than when such operations were more rudely performed and more tersely, if less scientifically, described. These secondary consequences are, *inter alia*, to render those on whom such procedures have been completely carried out, by the removal of both ovaries or Fallopian tubes, incapable of fulfilling what in every Christian community has been generally recognized as one of the chief functions and primary objects of woman's married life, namely, that of childbearing. I have already expressed my belief in the occasional necessity of such operations as the only available means of saving life in certain exceptionally urgent cases. But I need hardly add that, in my opinion, even in these they should not be resorted to without absolute and well-proven necessity, or without the patient's concurrence and full knowledge of all their consequences. Moreover, in obtaining such consent, it should be borne in view, as Dr. Wiglesworth has observed, that there are 'two ways of putting the nature of an operation before patients. If women were only told that by removing their ovaries they became sterile, few in these days would object; but if they were told in addition that by this operation they were completely unsexed, that sexual desire became feebler, that in a few years their voices would change and become somewhat masculine, and that in time the face would become "hairy" like a man—in fact, that a change would ensue somewhat similar to that which takes place in the larger animals after spaying, not one woman in fifty would consent to the operation, except it became a matter of life or death.'"

LIGATURE OF THE VERTEBRAL ARTERIES.—Dr. A. C. Bernays writes: "In your report of my case of 'Ligature of the Vertebral Arteries,' on page 221, August 21, 1886, an error has crept in which I desire to have corrected. In speaking of the high pulse-rate after the ligature, it is given as 180 per minute. This is an error; its greatest height was 100, and this lasted only a short time. The pulse gradually returned to the normal condition as the collateral circulation was more perfectly established."

CONTAGIOUS [illegible] IN BERLIN.—The police authorities of Berlin have ordered that every physician who is called to attend a case of puerperal fever shall report the same, within twenty-four hours, to the sanitary commission, giving also the name of the midwife who had charge of the case.

A SERIOUS OUTBREAK OF DIPHTHERIA is reported from West Cowes, in the Isle of Wight. It is stated that the sanitary condition of the town is about as bad as possible.

A NEW RUSSIAN JOURNAL.—It is announced in *Vyatch* [illegible] *and Petersburg Obstetrical and Gynecological Journal*. It is to be the organ of the recently formed Obstetrical and Gynecological Society of St. Petersburg, and the editors are to be Drs. Krassovski, Slavjanski, and Smolski.

A Curious Attempt at Deception.—A Russian peasant woman, who desired to pass off an infant as her own, in order to make it appear that she had just been delivered, procured the lung of a sheep to answer as a placenta and the seminal duct of a he-goat to represent the umbilical cord. The deception was discovered by Dr. Solovjeff, who relates the case in the *Volkhski Vestnik*.

Professor von Arlt, the well-known ophthalmologist, of Vienna, is reported to be suffering from gangrene of the foot following phlebitis and thrombosis of the leg. It was proposed to amputate the leg, but the patient's general condition is so bad that it is feared the operation may prove fatal.

A Short Method of Cure for all Diseases.—The latest religious sect in Russia has been founded on the dogma that it is a sin to let a fellow-member suffer the martyrdom of disease. Accordingly, when anybody falls sick, one of the believers goes to him and chokes him to death. The person commissioned for the deed is clad in red clothes and is known as "the red death." Unfortunately they do not confine their delicate attentions to the members of the sect alone, but, impelled by a broad charity, seek to cure in their peculiar way everyone, whoever he may be, who has the misfortune to become ill.

Bacteriotherapy.—Drs. Testi and Marzi report in the *Gazzetta degli Ospitali*, three cases of tuberculosis treated by inhalations of bacterium termo. In each case there was a marked diminution in the number of tubercle-bacilli found in the sputa, but in other respects there was no improvement, and the disease progressed steadily just as if untreated. The results of the experiments thus far made in this direction are not encouraging. They appear to show that there is an antagonism between the bacterium termo and the bacillus tuberculosis, but they also show that the disappearance of Koch's bacilli from the sputa is of no special moment. They merely furnish an argument for those who deny that any causal relationship exists between the bacilli and the tubercular process.

THE CHARLESTON MEDICAL RELIEF FUND.

We take great pleasure in announcing the following subscriptions, in answer to the appeal of The Medical Record for the relief of the suffering physicians of Charleston. The families of many of the physicians are still without sufficient shelter, and more funds are urgently needed. They will be sent without delay to responsible parties, who will take special pains to distribute them in a way to do the most good.

Obituary.

JAMES G. WAKLEY, M.D.,

LONDON, ENGLAND.

Dr. James G. Wakley, editor of *The Lancet*, died August 30th, of cancer of the tongue and fauces, at Heathlands Park, near Chertsey, England. He was the youngest son of the late Thomas Wakley, founder of *The Lancet*, Member of Parliament for Finsbury, and Coroner for Middlesex, and is survived by his brothers, Thomas H. and H. Membury Wakley, having been associated with the former as half proprietor of *The Lancet*. He became a member of the Royal College of Surgeons of England in 1849, and was graduated Doctor of Medicine at King's College, Aberdeen, in 1852. At his father's death, in 1862, he became editor of *The Lancet*, the duties of which position he discharged for nearly twenty-five years, continuing, in spite of much recent suffering, active in his work up to last Easter. Dr. Wakley proved himself a worthy successor in every way to his distinguished father. Through his painstaking labor, his journalistic skill, and his conscientious devotion to the best ideals in medical journalism, he has kept *The Lancet* against all rivals in the high position won for it by its founder.

JOHN BURKE, M.D.,

NEW YORK.

Dr. John Burke died of pneumonia at his home in this city, on September 8th, at the age of fifty-nine years. He came from his native town, St. John, N. B., early in life to study medicine in this city. He was graduated from the University Medical College in 1849. After graduation he began the practice of medicine in the lower part of the city. His practice was a very large one. He was a member of several local medical societies.

Posterior Luxation of the Upper Eyelid.—Dr. Dépoutout reports, in the *Journal de Medecine et de Chirurgie Pratiques*, a case of luxation of the upper eyelid behind the globe of the eye. A young girl, whose crooked nose and prominent eyes had earned for her among her playmates the nickname of "The Owl," was eating one day, when she suddenly experienced a peculiar sensation in the orbit, and putting her hand to her eye was horrified to find that the globe was almost entirely uncovered. Examination showed that the eye was in its natural rather prominent position, but the upper lid had slipped over it, and was concealed behind it in the cavity of the orbit. The reduction of the dislocation was easily performed, and no evil results, as regarded the vision of the eye, followed the accident.

FIFTY-FOURTH ANNUAL MEETING.

Held at Brighton, England, on Tuesday, Wednesday, Thursday, and Friday, August 10, 11, 12, and 13, 1886.

MEETINGS OF SECTIONS.

SECTION IN OBSTETRICS AND GYNECOLOGY.

THURSDAY, AUGUST 12TH—THIRD DAY.

Dr. [illegible] read a paper on

THE PROPER TREATMENT FOR THE HÆMORRHAGE OF LAPAROTOMY IN ABDOMINAL PREGNANCY.

In order to illustrate the point in question Dr. Lusk recorded the particulars of a case which had lately occurred in his own practice. Mrs. B——, after several attacks of peritonitis, was found to be suffering from an extra-uterine abdominal pregnancy. Having remained for some time under medical supervision, and the fact of the death of the child being fully established, it was suggested to her that she should undergo the operation of laparotomy, with a view to the removal of the fœtus. This, however, she declined. Some months later the general health was found to be rapidly failing, and signs of septic poisoning had fully established themselves. Under these circumstances she had almost determined to avail herself of the chance of relief offered by operation, but before doing so sought the advice of a medical friend, who advised her to go to the seaside and try first what change and climate would do. Very shortly, however, after reaching her destination health failed so rapidly, and signs of hectic became so marked, that she determined to return at once to New York and seek the help of Dr. Lusk. By this time the patient's strength was so exhausted that all hope of benefit from the operation seemed impossible. At the pressing request, however, of her friends it was decided that the abdomen should be opened. At the operation the sac of an abdominal pregnancy was found closely matted to surrounding parts; on opening the sac a fœtus was found in an advanced state of decomposition. The patient rallied from the operation, and for a time hopes were entertained of her recovery; but her strength had become so reduced that she failed to weather the period of recovery and gradually sank. It was clear that the time lost in temporizing and trying the effect of climatic changes allowed her to become so reduced that the chance of relief by the operation was lost.

The moral of such a case as the one just recorded is clearly this: "Is it not a mistake to wait long after the death of the fœtus before performing laparotomy?"

In studying the question the author intended to leave out the treatment of tubal gestation in the early months. The presence of a lithopædion is so rare, and so few cases are known, that they are no help in calculating the result of abdominal ectopic gestation. The question of waiting seems hardly to have been fully discussed, or its risks duly appreciated; cases are numerous where patients have sunk and died while waiting for the formation of these fistulæ; in other cases the process of elimination has extended over years, and even then complete recovery has not been perfectly obtained; in other cases operation has, after all, had to be resorted to, or the patients have been left to linger on in disgusting condition.

Dr. Lusk pointed out that the fatal cases after laparotomy had not been as carefully tabulated as was necessary, if the full value of the operation was to be impartially weighed.

In the fatal list might be found cases which had been left, and only sent for operation when the condition was past recovery; at other times operative measures had been undertaken on the dying—indeed, one might also have said, on the dead. Clearly, the lesson so far brought forward is, that with the first sign of failing health laparotomy ought to be done. Waiting was supposed to make the occurrence of hemorrhage during the operation less likely, and, again, to give time for the more perfect shutting off of the sac from the peritoneal cavity. The great risk of waiting was the insidious way in which septic trouble was apt to supervene; in America, certainly, the mistake had been made more than once of supposing the early septic appearances to be those of malarial poisoning.

The teaching, then, of all past experience is to warn us against waiting till the signs of septic poisoning may have manifested themselves, and rather to resort to operation while the patient's health is good and strength unimpaired. The question of operation during the life of the fœtus, and so endeavoring to save both mother and child, would naturally present itself in discussion; the possibility of this proceeding had been fully established by the now famous case of Dr. Jessop, but, as a rule, the question would always be a hard one to decide. In all cases, if possible, operative procedures should only be undertaken by those who had had considerable experience in abdominal surgery. One point in favor of early operation ought not to be overlooked, viz., that by opening the abdomen at an early period, before the cyst-wall had become matted to surrounding structures, there would be a better prospect of removing the whole sac.

Mr. Lawson Tait considered that the moral of the paper was, delays are always dangerous, and early interference wise.

Dr. Meadows recorded a case of abdominal extra-uterine fœtation operated on by himself successfully. The patient had come under his care two years after the termination of the full time of gestation. The abdomen was considerably enlarged and presented all the characters of an ovarian cystoma containing much solid material. After incising the abdominal wall the much-thickened sac was opened, and a macerated, but not decomposed, fœtus was removed. The cyst was stitched to the edges of the abdominal incision, and the patient made a perfect recovery. In this case there had been no signs of septic poisoning and the patient's health had continued good; delay had apparently acted beneficially by causing thickening of the cyst-wall, and so lessening the chances of septic absorption.

Dr. Wilson, of Baltimore, advocated the performance of laparotomy, as soon as the diagnosis of extra-uterine fœtation had been made, in all cases in which the application of electricity, the injection of morphia into the cyst, and such like expedients had failed. He recorded particulars of a case which had occurred in his practice, in which twins had existed, one of whom was born *per vias naturales*, and the other by abdominal incision from an extra uterine cyst. The mother died in thirty-six hours from septicæmia.

Mr. Jessop, of Leeds, wished to know why, as in his own well-known case, an operation should not be undertaken early, with the view of saving both mother and child. Was not the time while the child was still living the right one for operation, and what were the dangers of interfering then? In his own opinion, the best time to operate was the earliest time at which you met with the case; such had been his feeling when he undertook the case he had referred to, and the success gained might be a guide for others.

Mr. Alban Doran was of the opinion that the longer the delay the greater would be the thickening of the cyst-

wall. He recorded a case of extra-uterine pregnancy occurring in his own practice, in which the cyst-wall was found greatly hypertrophied and very intimately adherent to the surrounding tissues. The result proved fatal to the mother. In this case, had the operation been done earlier, the cyst and neighboring viscera would have been less matted together, there would have been a fair chance of removing the cyst-wall entire, and the mother's life would have been saved.

Dr. Edis thought that with our present knowledge we must treat each case on its own merits; different cases taught different lessons, and no one was quite a guide for another. The question of operating during the life of the fœtus was a difficult one to decide; there was little doubt it increased the risk to the mother. In his opinion the matter must be left at present *in statu quo*.

Dr. Berry Hart presented a report of

A SUCCESSFUL CASE OF ABDOMINAL SECTION FOR RUPTURED FALLOPIAN-TUBE FŒTATION, WITH MICROSCOPIC EXAMINATION OF THE PART OF THE TUBE REMOVED.

In the case recorded, the diagnosis of extra-uterine pregnancy advanced to the third or fourth month had been made, and abdominal section, with a view to its removal, had been advised; the patient, however, though warned of the risks she ran, refused to consent to the operation. Within a short time, however, symptoms of rupture of the sac supervened, and the patient, now alarmed at the possibility of fatal termination, consented to the operation. When the abdomen was opened the cyst was found ruptured and empty, and the fœtus lying loose among the coils of the small intestine. There was no difficulty experienced in the removal of the sac, and hemorrhage was easily stopped by pouring in water heated to 120° F.; the advantage of hot water as a controller of hemorrhage was so admirably illustrated in this operation that Dr. Berry Hart forcibly urged its employment in all similar cases. Discussing the advisability of abdominal section in all cases of ruptured extra-uterine pregnancies, the author quite admitted that cases of rupture do recover, but thought that, on the other hand, it was necessary to consider that a large number of these cases were ultimately seen on the post-mortem table. There was no difficulty in making the diagnosis when rupture had occurred, and the presence of intense anæmia would always serve to differentiate these cases from those in which the occurrence of somewhat similar symptoms was due to the swallowing of irritant poisons. The success obtained by Lawson Tait and other operators in similar cases was strongly in support of the opinions he had advanced, and would serve as an encouragement to others who were resolved to treat these cases on what was clearly the only rational plan. The author considered there was very little risk in operative treatment.

Dr. F. H. Aveling gave an account of

A CASE OF EXTRA-UTERINE GESTATION ARRESTED BY ELECTRICITY.

The history of the case was as follows: The patient, while living in the country, was attended by her doctor for repeated attacks of colicky abdominal pain, which was, however, relieved by hot fomentations and opium. After one of these attacks the symptoms of syncope and collapse were so marked that a consultation was deemed advisable. Vaginal examination having shown the presence of a tumor in Douglas' pouch, and the mammary and other signs of pregnancy having been found to be present, the diagnosis of extra-uterine pregnancy was now made. The patient having been removed to London, another consultation was held, and the presence of extra-uterine gestation being established beyond doubt, it was resolved to make an endeavor to check the further development of the cyst by the use of electricity. In carrying out this treatment a faradic battery was used; one pole was introduced into the vagina and pressed against the tumor, while the positive pole was placed on the abdomen over the site of the growth. After the fourth application it was noticed that the tumor had decidedly shrunk in size, and from this time all symptoms of pregnancy gradually disappeared, the catamenia was re-established, and the uterus underwent involution. When last examined the growth had so far shrunk as only to be represented by a small thickening in Douglas' pouch. In studying the history of this method of treatment, we find that it was first employed in France, but soon afterward followed out in England by Dr. Braxton Hicks, who seems to have been the first to have used the current without inserting the electrodes within the sac. In the case now under consideration retroversion of the uterus was probably the cause of the abnormal gestation, and similar cases are recorded by Dr. Meadows and others.

Dr. R. Petch read a paper on

EXTRA-UTERINE GESTATION TREATED BY GALVANO-PUNCTURE.

A case of well-marked extra-uterine gestation came some time ago under the care of the author.

The diagnosis was established beyond all doubt, the uterine bruit could be heard over a considerable area, the fœtal heart-sounds were audible, and pregnancy had probably advanced to the end of the fifth or beginning of sixth month. Desirous to try the effects of galvanism, Dr. Petch passed two needles connected with the battery into the sac *per vaginam*, and closely watched the result. After several applications of the battery the tumor began to shrink, the fœtal heart-sounds were lost, and the uterine bruit gradually ceased. Month by month the tumor grew gradually less, and the parts at the same time resumed their normal state; by the end of six months nothing could be felt of the growth but a small, hard mass, about the size of a chestnut, which lay behind and to the side of the uterus. It was noticeable that, though the fœtal heart-sounds ceased soon after the first application of the current, yet the uterine bruit was audible for some weeks later, or, in other words, the utero-placental circulation persisted long after the death of the fœtus. This last observation seems to teach us how important it is to wait some considerable time after the death of the child before operating, if we would avoid the risks of hemorrhage from detachment of the placenta. If gestation has in any case advanced over seven months, abdominal section ought to be performed for the sake of the child; but if the patient comes under our notice before the seventh month, there is no reason for considering the life of the child, and measures such as galvanism are clearly indicated. There is one point to be considered in connection with the use of electricity before the seventh month, and it is this—even if electricity fails, it in no way interferes with the performance of laparotomy at a later period. The only objection to electricity, which the author could think of, was that it might leave behind a shrunken mass, the presence of which might prove a complication in a later pregnancy. In his own case the patient had gone through a normal pregnancy recently, so this fear had not been realized.

Dr. Wright commented on the remarkable way in which the placenta is absorbed in cases of extra-uterine pregnancy and thought it bore on the way in which shrinking took place after the death of the fœtus.

Dr. Wylie drew attention to the difficulties of early and accurate diagnosis in extra-uterine pregnancy. He narrated two cases which had occurred in his own experience by way of illustration, and mentioned that in one of these the supposed pregnancy was found on removal to be an ovarian cystoma. In his opinion many cases were overlooked, owing to the difficulties of diagnosis.

Dr. Gardiner, of Montreal, thought that the occur-

rence of pregnancy under unusual circumstances, as for example after a long period of sterility, after an attack of pelvic inflammation, after operation, etc., was a guide to diagnosis. He gave particulars of a case observed by himself, and stated that he considered it unnecessary to pass the electrodes within the sac; it was quite sufficient to apply one pole in the rectum against the growth, while the other was pressed on the abdomen over the position of the cyst. In his own case, which was four months gone, one or two applications of electricity had been enough to arrest further development. Cessation of fœtal life was not enough of itself to remove all danger; his own patient, thinking herself cured, had insisted on leaving bed and getting about prematurely, with the result of bringing on pain, fever, and alarming symptoms for a time.

Dr. Edis condemned in the strongest terms those who looked on at a woman with a ruptured extra-uterine cyst and took no steps to open the abdomen; such conduct was little else than criminal. He thought that many of the cases of so-called arrest of extra uterine gestation were cases of mistaken diagnosis; pyo-salpinx, ovarian tumor, etc., were liable to be confounded with ectopic pregnancy. Galvanism should be used up to the end of the third month; at the sixth month the employment of galvanism was a mistake, and laparotomy was the operation indicated. In his opinion Dr. Retch had erred greatly in not allowing his patient to go on to the seventh month, and then undergo abdominal section. He narrated a case in which he removed a fœtus per vaginam by cutting with Praguelin's cautery into the sac. Once a sac had been tapped, further steps should be taken with a view to the removal of the tumor.

Dr. Routh thought these cases of ectopic gestation fell naturally into three groups. 1. Cases seen in the early months: here the placental souffle could be heard with the vaginal stethoscope at the sixth week, and diagnosis was easy. 2. Cases at mid-term: here, if rupture occurs, death is almost certain, therefore operation should always be undertaken. 3. Cases after the seventh month where the child is living: in these cases Cæsarean section is indicated and operation is a duty.

Mr. Lawson Tait pointed out that cases of extra-uterine pregnancy always arise owing to the absence of the epithelium and cilia of the Fallopian tubes; if the latter are present impregnation never occurs in the tube, and ectopic gestation is impossible. Rupture always occurs at the site of the placenta: when the latter was placed at the upper part of the tube, a fatal result was the rule; when at the lower, hemorrhage occurred between the layers of the broad ligament, and a favorable issue was often obtained. He protested against children in favorable cases being killed by galvanism or any such nonsense. In his opinion cases were never diagnosed until rupture had taken place.

Dr. Hanks narrated a case of extra-uterine pregnancy, and stated his belief that it was possible to diagnose cases before rupture had taken place.

Dr. Steavenson dwelt on the various forms of electricity used, and considered that men ought to know which was the best form to employ.

It had been supposed that the death of the fœtus was due to shock, but if the nervous supply of the fœtal heart is studied it will be seen how improbable such an explanation is. A shock sufficiently strong to kill the fœtus would be almost certain to cause the death of the mother.

Dr. Lusk thought that it was a matter of indifference whether galvanism or faradism was used, but had found by experience that the galvanic current had to be used in a much stronger degree than the faradic. Faradism could be used with much less discomfort to the mother.

In the early months electricity ought always to be tried, though it was not always successful; in one case he remembered the fœtus was supposed to have been killed, yet the tumor continued to increase and the child reached full term.

Dr. G. Ranney, of Michigan, read a paper on the

TREATMENT OF [illegible]

The author advocated in all cases treatment by compression with a many-tailed bandage. The latter was of service whenever for any reason it was necessary to check the secretion of the milk.

Illustrative cases were read showing how useful the method was in cases where the child was still-born, in incipient inflammation of the breast, or even in an advanced stage of inflammation. Rubber cloth with adhesive straps might be substituted for the many-tailed bandage. After the breasts had been brought toward the middle line, with a napkin between them (if necessary) to secure even pressure, the bandage should be tightened from above downward; by the time the lower part was finished the upper part would be ready for retightening; this process could be advantageously repeated two or three times. Mere continued pressure with the hand on the breast was sufficient to empty the distended mamma and give relief.

Dr. Edis confirmed this method of treatment.

Dr. Bantock used the method even when abscess had formed. He preferred strips of plaster to the many-tailed bandage.

Dr. Swayne was in the habit of opening abscesses and then using compression by means of strips of plaster.

Dr. Ranney in reply stated that he preferred the bandage to plaster, and that he never allowed abscesses to form.

Dr. M. Beverley read a paper in which he presented

A RECORD OF TWENTY CASES OF EMMET'S OPERATION FOR LACERATION OF THE CERVIX UTERI AND OF THREE FOR PROCIDENTIA UTERI.

In the author's opinion labor was always the cause for this operation. Usually there was a history of either rapid or instrumental delivery; the history of uterine phlebitis or cellulitis secondary to labor was common. Among the prominent symptoms of ruptured cervix might be mentioned backache, anæmia, sleeplessness, mental irritability, faceache, and leucorrhœa. Vaginal examination generally showed the existence of ectropion of the cervix, granular erosion, hardness of tissue, and a bulky uterus; much new tissue was always present. Dr. Beverley considered that much harm was done in treatment by the use of irritants, the cautery, etc. He had never found any difficulty in the performance of the operation. Out of the twenty cases recorded eighteen had healed by the first intention. Complete rest and hot-water injections were always used for ten days before operating, so as to ward off the possible occurrence of cellulitis. All the author's success had been gained in cases in which ordinary methods of treatment had been exhausted and failed. Reference was made to the use of the operation in staving off the onset of epithelioma.

In the second part of his paper Dr. Beverley commenced by describing the operation as laid down by Dr. Emmet. The great superiority of this procedure over Alexander's operation of shortening the round ligaments was dwelt upon. In the author's first case there was complete procidentia of twenty years' standing, and all forms of pessary had failed to give relief.

Dr. Gordon thought the operation for lacerated cervix, as done in England, was seldom carried out as Dr. Emmet advised. When carried out in the manner recommended by the latter the operation did much good, but badly executed it caused more harm than good.

Dr. Kelly approved of the operation for procidentia uteri, and described it with the help of diagrams.

Dr. Wylie thought that cases of fissure, with sub-involution and evasion, would be operated on much sooner in America; here they were treated unduly long by caustics and irritants.

Dr. Beverley briefly replied.

FRIDAY, AUGUST 13TH—FOURTH DAY.

DR. SAVAGE, of Birmingham, read a paper on

THE REMOVAL OF THE UTERINE APPENDAGES.

Though a great deal had been written and spoken about the removal of *normal* ovaries, yet it was very rarely that healthy glands were extirpated; in most cases the ovaries when removed had been found to be useless for their child-begetting function. There were cases in which the removal of perfectly healthy ovaries was justifiable, as when a pelvis was so contracted that the birth of a child *per vias naturales* was an impossibility, and again in some cases of myo-fibromata of the uterus, though in these latter cases the ovaries were generally found to have become diseased. The most common causes which led to symptoms indicating the need of operation were peritonitis—either ovarian or pelvic—or diseases of the tubes, such as arise from the spread of the gonorrhœal inflammation upward from the vagina. The first class of cases (ovarian peritonitis) often follows a miscarriage or confinement, and is septic in nature. A typical case of this latter class often presents the following history: There has been a confinement, followed by puerperal inflammation; then comes a long period of sterility; later, much pelvic pain is complained of; vaginal examination shows the ovaries to be enlarged and tender, while the general health is more or less wrecked. In former times the occurrence of gonorrhœa in the female was considered a very trifling accident, but with our present knowledge we are bound to look on every such patient as exposed to the risks of pyo-salpinx. We really want to know the pathological importance of (1) atrophied ovaries, and (2) enlarged ovaries. It is still a question where the line is to be drawn between enlarged hypertrophied ovaries and ovarian cystoma, nor is the connection between adherent appendages and cystoma fully established beyond all possibility of discussion. To the inexperienced, difficulties in diagnosis must be common, but in many cases enlarged tubes can be easily mapped out; moreover, the symptom of metrorrhagia often serves as a valuable guide. In acute pyo-salpinx the temperature is a guide, but it lends no aid in chronic cases. The effect of chronic disease on the ovaries is to render these latter rotten and pultaceous; the glands in such cases are useless in the female economy and their removal is clearly beneficial. The frequency with which blood-collections occur in the tubes has been much questioned; in the author's experience they are much more common than text-books would lead us to imagine. Referring to those cases in which hemorrhage from the uterus continued after the removal of the appendages, Dr. Savage was of the opinion that these cases did not often depend on imperfect removal of the ovaries and tubes, but he had no explanation to offer of the causes of such an accident. In the operation itself there should be no difficulty, except in cases where the disease was of old standing and strong fibrous adhesions were found to exist. No case ought to be beyond the skill and resource of an operator; cases which in former years he had himself left uncompleted owing to the difficulties of removal, he would now with his increased experience certainly finish; it was a reproach on our skill and dexterity if we allowed ourselves to be vanquished by the difficulties arising from old adhesions or matting of the tissues to surrounding structures. Now and then bleeding might be profuse, but it could always be controlled by pressure. In every case early operation was very desirable, and it was everything to catch the case at an early stage. Patients in whom the ovaries were adherent and buried in a mass of inflammatory exudation were most frequently the subjects of the operation, and next in order of frequency came the cases of distended Fallopian tubes. In opening the peritoneal cavity a short abdominal incision was desirable, because though it is a matter of small consequence whether the abdominal wall is divided for an additional inch or two, yet the longer the incision the greater the opportunity for septic absorption. Another advantage of a short incision is that the intestines are less likely to prolapse.

DR. MORE MADDEN also read a paper on

THE REMOVAL OF THE UTERINE APPENDAGES.

The operation for removal of the uterine appendages is indicated principally in three classes of cases: (1) In certain cases in which disease of the Fallopian tubes exists; (2) in some cerebral cases secondary to ovarian irritation; (3) in fibro-myomata of the uterus. No doubt could exist of the possibility of operating, and there could be no question as regards success, but the real point at issue was, with what degree of frequency ought the operation to be done. In deciding this question the consensus of opinion of gynecologists as a body ought to be taken, and the matter should not be left to the dictum of a few operators. There was no doubt that ovaries were being removed with growing frequency; as Dr. Carter had pointed out, the gynecologist removes a woman's ovaries with as little hesitation as a butcher spays his cows, and with about the same amount of regard for his patient. The operation, moreover, was not always successful in its results, for, to the author's own knowledge, many women in New York who were minus their ovaries and tubes still attend the hospitals and suffer as much as ever, if not more. In view of the fact that so many ovaries were about to be taken away, it was highly desirable that a discussion, ethical, moral, and surgical, should be held. In spite of all that had been said and argued to the contrary, the ovaries were to a woman what the testicles were to men, and to remove either without unsexing the patient was simply an impossibility. Childbearing was woman's function and woman's privilege, and every woman ought to be told the result of the operation before it was done.

The mere change of voice and growth of hair need not be weighed; there were other and far more important results. Considering the increased frequency of the operation one was bound to ask, Does this increased number of öophorectomies depend on an increased frequency of salpingitis, ovaritis, etc.? So far, Dr. More Madden had not found such to be the case. No one could say that ovarian and tubal diseases were disorders but lately recognized, for these complaints had been diagnosed and treated long before the present rage for operating had come in.

Even among modern operators there is much difference of opinion as regards the frequency with which öophorectomy should be done. The statistics of Sir Spenser Wells were interesting in this respect. The author's own experience, from observations made in the dissecting and post-mortem rooms as well as in practice, was that *grave* tubal or ovarian disease was rare; therefore he hoped to-day to hear some good reasons given why the operating mania should have so suddenly sprung up. In the causation of disease of the uterine appendages extension of septic mischief after delivery was the most common factor; next in order came gonorrhœa and catarrhal disease. In some of these cases aspiration would succeed, and in others, treatment leading to resolution.

Öophorectomy had its most useful application in cases of uterine myomata, though even here it should not be used indiscriminately in young patients. There was always one point to be borne in mind, viz., that a myoma did not usually lead to a fatal termination, while the same could not always be said of the operations for its cure.

In cases of old, quiescent fibroids an operation should not be undertaken, nor, again, in those cases where the ovaries might be expected to be found deeply placed behind the growth. It was probably useless for any one man to endeavor to stem the present epidemic of operating mania, but he felt bound to enter his protest; it would be a matter of deep regret if a useful operation

should fall into reproach, and become obsolete, because at present its most ardent exponents insisted on practising it in an indiscriminate and reckless manner.

Dr. Bantock thought that there were two great classes of disease in which removal of the uterine appendages was indicated: (1) When the appendages were the seat of some disease, such as pyo-salpinx, etc.; (2) when the appendages were healthy, but were removed for some neighboring disease. In the first class of cases, after rational and constitutional treatment had been tried, operative measures must be resorted to. A word of warning was necessary lest constitutional treatment should be too contracted, and so the result of the operation marred. In cases of papilloma of the tube, abdominal section was the only resource. If acute ovaritis, chronic ovaritis, ovarian cirrhosis, cystic degeneration of the ovary, or extreme atrophy of the ovary existed, the operation for removal was indicated. In all these conditions pain was a constant symptom. Acute ovaritis was so rare a disease that he had never seen a case of it; considering that during senility ovarian atrophy was always normally present, it was curious that such severe symptoms should arise from the above-mentioned cases of extreme atrophy. In the second class, in which neurotic diseases, epilepsy, etc.—were included, the operation was doubtful, and at best only tentative. To perform the operation in every case of insanity was certainly wrong; but if the disease arose or became intensified at the menstrual periods, operative measures might be tried. With small myomata, operation might be needed, but we must not overstep the boundary of prudence; in many of these cases dilatation of the cervix, scraping, and the application of iodine, or enucleation, ought first to be tried. Roughly speaking, one might say that if the tumor weighed two to three pounds and was growing quickly, then oöphorectomy was indicated; but if the tumor weighed only about one pound and was descending through the os uteri, the removal of the uterine appendages was unjustifiable. The operation had been done for dysmenorrhœa, menorrhagia, and displacements of the uterus, but in these cases it was certainly wrong.

Dr. Bantock protested against the excessive frequency of the operation, and felt that the warning note was needed. The case of the unfortunate Mr. Baker Brown was still in our memory, and served as an illustration of the necessity for caution.

Dr. Gordon, of New York, was of the opinion that in the question of operating every man must decide for himself; those who saw most of these cases would be the men most competent to form an opinion. It was not always possible to judge by physical signs; he had himself, in some cases, removed tubes and ovaries when there was absolutely nothing to be made before the operation by physical examination, and yet the success gained justified his decision. If operation is certified by result, then other men's *dictum* is worthless.

Dr. Elder, of Nottingham, wished that Dr. Savage had said more about alternative measures. To his mind the subject should be considered under three heads: (1) In connection with uterine myomata; in certain of these cases the operation was certainly called for. (2) Oöphorectomy for disease of the ovaries other than ovarian cystoma. In cases in which the ovaries are enlarged and adherent, and where menhorrhaga or metrorrhagia is present, there can be no doubt of the advisability of operating. In all cases the patient's friends ought to be informed of the proposed operation, and the effect ought to be clearly explained to them. In cases of extreme atrophy of the ovary removal was justifiable; but oöphorectomy for neuroses gave disappointing results. (3) Accumulations of blood, pus, or serum in the tubes, etc. In cases of hæmato- and pyo-salpinx operative measures were called for, but in every case the diagnosis ought to be based on objective as well as on subjective signs, and other treatment should have been given a trial first. The patient's consent must of course be always obtained.

Dr. Imlach thanked Dr. Savage and Dr. More Madden for their papers, and felt sure that discussion on so important a topic would be welcomed. In many of these cases of disease of the uterine appendages only two courses were open, either to cure your patient by operation or to send her home as incurable. It was not fair for men who were ignorant of, or had no experience in, these cases to offer criticism; a man ought to go to the Hospital for Women, either in Birmingham or Liverpool, and investigate for himself. Unjust criticism could always be met by seeing the cases referred to before they had been operated on, and again six months afterward. Disease of the uterine appendages might occur at any age, but pyo-salpinx was seen most frequently in young women. It was idle to say that women do not die of this disease; uterine disease, both chronic and acute, is a frequent cause of death. In every case Dr. Imlach made it a rule to explain to the patient all the risks and results of the operation. In cases of prolapsed ovaries he should not operate unless severe symptoms arose; in any case he did not remove the uterine appendages for ovarian prolapse, but preferred to stitch them up to the pelvic brim and so suspend them. The latter operation relieves pain, and occasionally has proved a cure for sterility. Men who only occasionally operated were much more likely to remove the appendages in unsuitable cases than those who had had greater experience.

Dr. Wylie agreed with the previous speaker. He had been one of the first in New York to take up the operation for the removal of the uterine appendages. Before commencing operative measures he had spent two years in perfecting his diagnostic skill, and even now he made a point of watching every case for some time before undertaking a surgical proceeding. At present he could always recognize cases of pyo-salpinx before operation. A man who was known as an operator would, of course, get more of these cases than other men. He made it a rule to preserve all appendages removed, and was then able to show them in confirmation of the necessity for operating. All great advances in surgery were sure to pass through a testing time.

Dr. Davies, of Liverpool, stated that the pathology of the tubes was a much simpler matter than that of the ovaries. In most cases of hæmato- pyo- and hydrosalpinx operation was needed, and nothing else would avail.

Dr. Wilson, of Baltimore, thought that the need of operative measures in many cases was undeniable; but the pendulum had probably swung a little too far. In cases of bleeding myomata of the uterus the latter organ should be opened up, the site and attachments of the tumor located, and then, if enucleation was impossible, oöphorectomy should be performed.

Mr. Lawson Tait agreed with all that had been said by Dr. Savage. He regretted greatly that so many misrepresentations had been made concerning the operation. Spaying was a mistaken term, as it implied the removal of ovaries before the onset of puberty. In the experience of men who had a special reputation for this operation the number of cases would, of course, be considerable.

Dr. Kelly, of Philadelphia, thought a protest was needed against over-frequent operating. He should always refuse to complete the operation, whatever the symptoms might be, unless he could find diseased tissue at the time of operating.

Dr. Graily Hewitt felt it would be difficult at present to lay down any hard or fast rule for operation. The question of diagnosis was all-important, and full care had been taken to perfect this. He dwelt on the chronicity of certain diseases in connection with the generative organs. Malnutrition of the body was often the great obstacle in obtaining a cure, and therefore attention directed to that point was urgently needed; the use of massage might be considered in this connection. Oöphorectomy was justifiable in some cases of chronic

displacement of the uterus. Much had been learned lately regarding the harmful action of gonorrhœa, especially when the latter had become chronic.

Dr. Vincent Jackson, of Wolverhampton, thought it would be a great gain if experienced operators would publish the results of these operations twelve to eighteen months after they had been done.

Dr. More Madden having briefly replied, a vote of thanks was given to the President, on the proposal of Dr. T. Savage, seconded by Dr. Gordon. The President conveyed the thanks of the section to the American visitors for the share they had taken in the work of the section, and Dr. Wilson, of Baltimore, briefly responded.

Correspondence.

OUR LONDON LETTER.

From our Special Correspondent.

THE BRADSHAWE LECTURE—COLLEGIATE RESIDENCE FOR MEDICAL STUDENTS—INSANITATION AT THE HOUSES OF PARLIAMENT.

London, August [illegible], 1886.

Not a very large audience assembled at the College of Physicians, on the afternoon of Wednesday last, to hear the annual "Bradshawe Lecture." The wisdom of fixing the date of its delivery at a time of year when only those are in town who cannot get away is more than doubtful. On this occasion the lecturer was Dr. Julius Dreschfeld, Professor of Pathology at the Victoria University, and Physician to the Manchester Royal Infirmary. At the best, Dr. Dreschfeld is not an orator calculated to "draw" a large audience. He is a practical physician, a skilled pathologist, and a scientist who keeps himself well abreast of the most recent advances in medicine; oratory, however, is not his *forte*, and the less said about his "delivery" as a lecturer the better.

Turning from manner to matter, more appreciation can be expressed. Dr. Dreschfeld took for his subject "Diabetic Coma." Sudden death, he said, was not uncommon in diabetes, yet the term "diabetic coma" was by no means applicable to all cases, though coma might be a chief symptom.

Thus coma might be due to cerebral hemorrhage. Acute croupous pneumonia might occur in diabetes and cause death without the usual pulmonary symptoms, the chief phenomena being dyspnœa and coma. Death in coma might result from interstitial nephritis complicating diabetes. It might also result from intercurrent affections.

The lecturer then went on to speak of the kinds of diabetic coma, and referred to a paper read by himself before the Midland Medical Society, in 1881. In this he had differentiated three chief forms. Twelve months later Frerichs had expounded the same views and adopted an identical classification.

The first of these forms had been recognized by Prout; it was that of "diabetic collapse." It consisted in the development of drowsiness, with extreme coldness of the surface, quick pulse, and shallow breathing. The urine contained from five to eight per cent. of sugar, a little albumen, but no aceto-acetic acid. Active delirium and convulsions were absent. The pupils, though sluggish, reacted to light. Death occurred, with falling temperature, in from ten to twenty hours. This form was most frequent in persons above forty who had suffered from diabetes for some time, and who were, as a rule, stout and well nourished.

In the second or "alcoholic form" of diabetic coma, the patient had all the appearance of acute alcoholic intoxication. Several cases of this variety were described. One was that of a middle-aged man who had been in hospital for diabetes. While walking in the garden he suddenly exhibited symptoms of alcoholic intoxication. Deep coma and death soon followed. The urine drawn from the bladder showed, besides sugar, a considerable amount of alcohol. It was clearly proved that the patient could have had no access to any alcoholic liquor.

POSSIBLE EXTENSION OF MALARIAL DISORDERS BY MEANS OF WATER-SUPPLY.

To the Editor of The Medical Record.

Sir: As you are aware, I have been pursuing the inquiry in regard to the possibility of the extension of malarial and intermittent fevers by the use of water from streams along whose banks diseases of this type are endemic. It is somewhat difficult to secure unbiassed testimony in regard to the matter, because of the implied interference with the "vested rights" of water companies. Nevertheless, it is for the interest of such corporations, as well as their patrons, that any evidence bearing upon this point should be examined carefully.

Recent researches in regard to the extension of cholera in Spain make it highly probable that running water does not readily purify itself, at least not so far as the contagion of cholera is concerned. There is ground for the belief, also, that the poison of typhoid may be conveyed long distances in running water. In the very nature of the case these diseases, propagated in this way, occur in localized epidemics, due to accidental contamination of the water-supply. A sudden outbreak of sickness of this sort naturally excites earnest inquiry in regard to its causes. The attention of sanitary authorities is aroused and a thorough investigation is begun at once. But in the case of diseases of a malarial type the condition of affairs is quite different. If water indeed serves as a vehicle for their conveyance, it is by a more gradual process. Years may be required to bring into general use the water from a public water-works, so that its full effect can be seen. The increase of the disorders in question has been so insidious that their source is overlooked. For this reason the problem is much more difficult than in the case of a single well-defined outbreak of disease, which may be shown to be plainly due to temporary contamination of the water in use. If, however, instances such as one within the knowledge of the writer can be shown to be not uncommon, it is evident that we have to deal with a very grave subject.

In a town of considerable size, which shall be nameless, the inhabitants years ago were, as a rule, entirely free from malarial diseases, except along the banks of the adjacent river. During the writer's acquaintance with this town, which was extensive and of long standing, he never heard of these diseases prevailing except in the immediate vicinity of the stream in question. Some years since a system of water-works was introduced, taking the water from this river, whose surroundings were positively and unquestionably malarial. Soon intermittent fevers and allied disorders begun to prevail throughout the town, and have not ceased so to do every year subsequently. Where once they were practically unknown they now are very common. It is as if the inhabitants all lived close to the banks of the stream. They have not gone down to the river, but the river has come up to them. Whether it is the use of such water for drinking purposes, or the saturation of the soil in various ways by its means, that may be presumed to extend these diseases, is to the writer as yet unknown. Perhaps further investigation may show that the case which has been described is of an exceptional character, but it certainly has impressed upon the mind of the writer the conviction that the subject is by no means unworthy of further research.

Yours, respectfully,

M. A. Veeder.

Lyons, N. Y., August [illegible], 1886.

IN REFERENCE TO "WHAT CAN WE CURE?"

To the Editors of The Medical Record:

SIR: It is hardly possible that the article under the above title in THE MEDICAL RECORD of August 21st will have no replies. If the term *cure* be used rather liberally, as by the correspondent from Missouri, surely the answer to this question may be, even in this day of pathological investigation, a large number of diseases. We are advised to "father no prescriptions," unless it be for opium or alcohol. Allowing due praise to opium in its various uses, it must still be the unfortunate hobby of a practitioner with whom it outweighs the whole materia medica. We will say nothing of the number of people who are its victims, even where its use was rationally begun. Besides opium, alcohol, and quinine, can we do nothing with aconite, bromides, digitalis, hydrargyrum, iodides, or iron? That collyriums have never cured acute ophthalmia is certainly untrue outside of Keytesville. I am one of those "fanatics" who occasionally "slander" alcohol, although admitting its power to keep the heart "wagging"—and the tongue as well. I believe that aconite and quinine, with or without cold sponging, have done as much by controlling the height of fevers as alcohol has done by supporting vitality during their decline. "A doctor's faith in physic is the measure of his intellect. It is always in inverse proportion." Is not, then, the surgeon's faith in the knife and ligature in inverse proportion to his intellect? When he sees a carcinoma let him rest with "confidence in God and nature" and leave it, as a certain Irish army surgeon preferred to leave bullets, to "festher oot." He says "the strife between nature and art in the cure of disease has resulted in a victory for the former."

Perhaps the opponent of nature in the strife at which the correspondent umpired was a *lack of art*, for true medical art has not been at strife with nature.

GEORGE S. WRIGHT, M.D.

New [illegible]

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 5 to September 11, 1886.

WAKEMAN, WM. J., First Lieutenant and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for three months' extension, to take effect when his services can be spared in the Department of the Platte. S. O. 207, A. G. O., September 6, 1886.

WALES, PHIL. G., First Lieutenant and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for an extension to November 5, 1886. S. O. 70, Division of the Pacific, August 31, 1886.

BANISTER, WM. B., First Lieutenant and Assistant Surgeon (recently appointed). To report by letter to the commanding general, Department of Arizona, for assignment to duty. S. O. 208, A. G. O., September 7, 1886.

WALKER, F. V., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort Adams, R. I. S. O. 131, Division of the Atlantic, September 8, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ending September 11, 1886.

WOODRUFF, C. E., Assistant Surgeon. Ordered to Receiving Ship Vermont, October 4, 1886.

ATLEE, L. W., Assistant Surgeon. Detached from the Vermont, and ordered to the Quinnebaug, per steamer of 25th inst.

BOGERT, E. S., Medical Inspector. Detached from the Trenton, and placed on waiting orders.

FEREBEE, N. McP., Surgeon. Detached from the Trenton, and placed on waiting orders.

BIDDLE, C., Passed Assistant Surgeon. Detached from the Trenton, and placed on waiting orders.

SCOTT, H. B., Assistant Surgeon. Detached from the Trenton, and placed on waiting orders.

Medical Items.

CONTAGIOUS DISEASES IN THE CITY.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 11, 1886:

[illegible]		
[illegible]		
[illegible]		
Measles		
Diphtheria		1
Small-pox		
Yellow fever	1	1

AN EARLY LAPAROTOMY.—Dr. T. E. Murrell, of Little Rock, Ark., writes: "Apropos of the prominence which laparotomy now holds before the medical world, I wish to call attention to a bit of oral history obtained through my father. When a boy, then living in East Tennessee, he heard a man named Bailey narrate to his father (my grandfather) the details of an operation performed by a surgeon on his (Bailey's) father, he himself assisting the surgeon in such way as he could. His father had been suffering for some days from obstruction of the bowels, and every available means failing to relieve him, and his condition growing more and more grave, the doctor decided to open his abdomen and see what was the matter. This he did, exposing the intestines and carefully examining them. He found one of the small intestines abruptly twisted upon itself, completely closing the lumen. This he unwound, and having replaced the bowels, sewed up the wound which he had made, and his patient made a perfect and speedy recovery, and lived many years afterward. From my father's age at the time he heard Bailey relate this circumstance, and the length of time the elder Bailey had been dead, and his having lived several years after the operation, he says it could not have been later than 1805, and perhaps several years sooner. My father was born in 1809, and has a most vivid recollection of what he saw and heard in boyhood. Living in a new and sparsely settled country, such occurrences were likely to become traditional. I have at long intervals questioned my father in reference to the above story, and he has invariably corroborated every detail in so far as was made known to him at the time when first heard, and, from the source, he does not question its truth. It is more than likely that we here have a case of ileus relieved by laparotomy, performed by a pioneer surgeon about or before 1805. I wish I had more direct testimony. Perhaps some *old resident* of East Tennessee, near the Virginia line, may be able to give it."

DENVER MEDICAL COLLEGE.—We are sorry to note that this institution is at its old tricks again, viz.: advertising itself and secretary in the daily press. This is wrong; it is unethical; it is very bad taste; it is a violation of the spirit, if not the letter, of the code of ethics of the American Medical Association.—*Denver Medical Times.*

A Flameless Disinfecting Lamp.—The Paris correspondent of the *British Medical Journal* gives a description of a flameless lamp for disinfecting the sick-room. It consists of a spirit-lamp and a spiral thread of platinum about fifteen millimetres in length. In order to use the lamp, it must be filled with alcohol at about 90°. The wick is moistened, and the spiral thread, having been previously soaked in alcohol, is so placed that it surrounds the wick as closely as possible without touching it. This last precaution is essential. Then the lamp is lighted, and the platinum-thread immediately becomes red-hot. Two or three minutes afterward the lamp is put out by using a glass extinguisher. Currents of air must be avoided, as they make the lamp flicker, and the platinum-spiral is then exposed. As soon as the lamp is put out the extinguisher is removed from it; the spiral remains incandescent, and continues in this condition so long as there is alcohol in the lamp; it then gives out a sweet etherized odor, and the most mephitic air is quickly purified. In a smoking-room, where generally the smell of smoke is persistent, all odor disappears after the flameless lamp has been used. In order to understand this somewhat complex phenomenon it is necessary to remember that hammered as well as spongy platinum possesses, at a very high temperature, the property of condensing gas, and facilitating in its pores the combination of the oxygen of the air with combustible gases. The reflex action must not be forgotten; the heat given out by the spiral provokes an abundant evaporation of alcohol. The vapor of alcohol, in passing upon the incandescent platinum, is decomposed, and liberates its oxygen, of which part goes to increase the incandescence. Thus the incandescent platinum accelerates the evaporation of the alcohol, and *vice versa*. The rest of the oxygen which is set free spreads about the room, and renders the atmosphere wholesome. It is possible that the vapor produces ozone and aldehyde. The production of aldehyde is more probable than that of ozone. The manufacturer of this lamp asserts that ozone is produced when a small quantity of a liquid which he calls ozogene, and contains ether, is mixed with the alcohol.

Uses of Potassium Chloride.—At the recent meeting of the American Medical Association, Dr. A. F. Pattee, of Boston, communicated a paper on potassium chloride. He had used it in many cases of anæmia with success, and had also found it beneficial in the first stage of hepatic cirrhosis. Inflammatory exudations—*e.g.*, pelvic cellulitis—and glandular enlargements subsided under its use. In stomatitis it was equal to the chlorate. He had also used it in ovarian neuralgia and menstrual headache, where it was more reliable than the bromides. Combined with corrosive sublimate it was one of the best remedies for syphilis. In cellulitis he gave it in ten-grain doses every three hours. He had also used it in epilepsy, finding it most serviceable in anæmic cases.—*Philadelphia Medical News*, July 5, 1886.

Fluoride of Ammonium is recommended by Dr. J. Lucas, of Bombay, in the treatment of hypertrophy of the spleen. He states that it excels any other method of treatment with which he is acquainted. It is administered in small doses (five drops) of a weak solution (strength not stated), and given after meals to prevent a purgative or nauseant action.—*Prov. Med. Journal.*

Therapeutical Notes.—Professor Da Costa considers aconite *the* remedy for *cerebral congestion*, combined with the bromides and laxatives, or even bleeding in the severer forms. Professor Bartholow considers jaborandi the most efficient remedy we possess for *alopecia*. For local application, he combines with equal parts of soap liniment the fluid extract, or one part of fluid extract of jaborandi, one of tincture cantharides, and two of soap liniment. Dr. Neff still continues to be successful in the treatment of asthma with *pyridine*. He has now had fifteen cases in which he has used it, without a single failure. In several cases in which he has used it a number of times, the number and severity of the attacks have seemed to be lessened. Whether these are cases of *post hoc* and not *propter hoc* only a larger experience can decide.—*Coll. and Clin. Record.*

Turpentine in Malignant Tumors. — Professor Vingt, of Barcelona, employs a hypodermatic injection of one part of turpentine and two parts of alcohol in carcinoma and sarcoma, and has frequently succeeded in causing these neoplasms to disappear. A local inflammation, with fever, lasting eight days, was the usual consequent.—*Therap. Gazette.*

Long-continued Albuminuria. — We once asked Dr. Johnson how long he had known a case of albuminuria to extend. He replied, thirty years. We may safely conclude that a disease which could be extended over thirty years might, with more care, extend over forty, and leave life very much uncurtailed. But this implies great care on the part of the patient and physician alike.—*Lancet.*

A Question of Priority in the Treatment of Asphyxia of the New-born.—Dr. George H. Noble, of Atlanta, Ga., writes: "I was very much surprised to see, in The Medical Record of July 3, 1886, that Dr. L. N. Sharp, of Minneapolis, Minn., was claiming my method of treating asphyxia in the new-born from syncope or anæmia of the brain. I was surprised that the doctor did not give me credit for it, as my article upon that subject was published in the *Amer. Jour. of Obstetrics and Diseases of Women and Children* in April, and copied into *Gaillard's Medical Monthly* of May, and in the June number of the *New Orleans Medical and Surgical Journal*. I was surprised to see that parts of his article read very much like parts of mine; and further surprised to see that Dr. J. C. Roberts, of Pulaski, Tenn., was making a similar claim in The Medical Record of July 31st. I would therefore be pleased if you will kindly publish this note, that these gentlemen may know of *my priority over them both*, for I fear that they are not very extensive readers of the medical literature of the day. It seems that a man in the medical atmosphere that Dr. Sharp is would have access to all the leading medical journals of this country, though he may not subscribe to them. It sometimes occurs that the same thing is discovered by different parties about the same time, and it may be the case in this instance; nevertheless *I have the priority*—unquestionably."

The Watermelon Vine as a Source of Musk.—Dr. A. G. Chase, of Millwood, Kan., writes: "In a recent number of The Medical Record I called attention to the tip ends of the watermelon vine as a probable source of obtaining musk. I collected a quantity of the young ends and made an aqueous extract, evaporating to a waxy consistence. I have used it in the form of pills in two cases, as a nervine, with very prompt and decided action. I would like to call the attention of pharmacists as well as physicians to it, for further examination. I have been very partial to moschus for many years, in the nervous and hysterical symptoms of young girls."

Abortive Treatment of Mammary Abscess.—Dr. A. G. Chase, of Millwood, Kan., writes: "Dr. Eliot, of Washington, D. C., in The Medical Record of July 31st, speaks highly of spirit of turpentine as an abortive of mammary and other suppurations; and while I know it to be good, I would like to call attention to what I have found to be a much better remedy, to wit, extract of belladonna. I generally use the solid extract, rubbed up with enough simple cerate to soften; or paint with fluid extract of belladonna ʒ ij., tincture of iodine ʒ j. I never fail in arresting suppurative tumors when the application is made any time before the formation of pus."

It is better to be sure than sorry;
It is better to know than to worry.

THE COEXISTENCE, OR THE COMPLICATION, OF ANAL FISTULA WITH PHTHISIS PULMONALIS.

Its Pathology, Treatment, and Cure, Considered with Reference only to the Operation.

BY WILLIAM BODENHAMER, A.M., M.D.,

THE subject of the association of anal fistula with phthisis, and the conflicting opinions concerning its treatment or non-treatment, when found thus connected, are of late being discussed, *pro et con*. This discussion reminds me that about forty years ago I paid some attention to this subject, and I feel disposed to give some of the views I then entertained concerning it to the profession now, for what they are worth.

The consideration of the copresence, or the complication, of fistula in ano with phthisis involves a most interesting and important point regarding its pathology, treatment, and cure; and it will be perceived that this subject has engaged the minds of the [illegible] our profession.

I will now introduce the subject by remarking that fistula in ano, when not connected with morbid conditions of the lungs, intestines, or other viscera, equally incurable and fatal, may be regarded as one of the most simple and satisfactory subjects of surgical practice. Indeed, it derives nearly all its difficulties and dangers from diseases that complicate or succeed it.

An anal fistula may exist in a phthisical patient without either disease becoming immediately complicated; for it is possible for the two diseases to exist in the same patient at the same time without either becoming involved in the other. Sooner or later, however, they may become involved to such an extent that neither can be cured. The two diseases may also be complicated, and stand in the relation of cause and effect, as they doubtless do in the majority of instances. Indeed, to repeat, an anal fistula may be associated with phthisis in two different characters—first, as a contemporaneous but independent accident, and secondly, as a consequence. Both diseases, too, may be produced by the same cause at the same time—that is, the same agent or low condition of the system which predisposes to the one will aid in the development of the other.

If the writings of the authors who have more especially studied the subject of anal fistula be consulted, it will be found that the earliest of them make no allusion to the disease being in any way connected with phthisis; and, although the more modern writers have adverted to the copresence of the two diseases, they have, for the most part, considered the phthisis in the light of a cause, instead of the consequence, of the anal fistula.

Now it must be admitted, by all accurate observers who have had much experience in the treatment of anal fistula, that it sometimes coexists with phthisis without exerting any favorable or unfavorable influence upon the latter, the two diseases being, as it were, independent of each other; and it must also be admitted that anal fistula is much more frequently complicated with phthisis, and is often the result of it, and when this is the case the two diseases may mutually react one upon the other, but unfavorably to each.

I will now show that, not only is the frequency of the connection of these two diseases denied, but when it does occur, the influence which one exerts over the other is also denied. As a confirmation of this, I will quote from the classical works of Laennec, Andral, Louis, Clark, Quain, and Gross:

M. Laennec says: "It is a common opinion, strengthened by the adoption of it by M. Bordeu, that phthisical subjects are particularly liable to fistula in ano, which helps to protract the termination of the disease. I have seldom observed this complication, and when it existed, it has appeared to exert no influence over the progress of the case."[1]

M. Andral says that he had met with only one instance of fistula in ano in eight hundred patients manifestly affected with phthisis in different stages, and he expresses a decided judgment against the commonly entertained opinion that this connection is frequent.[2]

M. Louis says: "I have not been any more successful than M. Andral, and I can readily account for the common error on the subject of fistula in ano in phthisical subjects by the habit, still adopted by medical men, of making analysis of their cases by the aid of memory—that is, of attempting impossibilities—and obstinately refusing to count in cases where it is obvious that that process cannot be dispensed with."[3]

Sir James Clark also says that, although he has often met with fistula in ano, he has not been able to trace any connection between it and phthisis further than its probable dependence on abdominal plethora, which so frequently precedes the latter malady.[4]

Mr. Quain says: "The belief which has long commonly prevailed, that there is a proneness to the formation of fistula in ano among persons laboring under pulmonary phthisis, has, like several other opinions resting on general impression, been shown not to stand the test of the strict observation of facts."[5]

Dr. Gross says: "It is a pretty common opinion that phthisis frequently gives rise to anal fistula, establishing thus, as it were, a sort of an issue which, by diverting from the affected organ, retards, as is supposed, the progress of the original malady. Respectable as the authority certainly is by which this notion is sanctioned, it is entirely at variance with the experience of every intelligent observer of the present day. The circumstance, I am convinced, is in a great measure, if not wholly, accidental; at any rate, I can truly say that it has rarely occurred in my practice, nor have I witnessed it more than three or four times in my dissections of phthisical subjects."[6]

The following extract of a letter, addressed to the writer, is from the late and lamented Dr. W. A. McDowell, who during his life treated more cases of consumption than any other physician in the Mississippi Valley:

"DR. BODENHAMER:

"DEAR SIR: Yours of the 29th ult., relative to complications of fistula in ano with phthisis, was duly received. That the complication is frequent, and that the

[illegible]

H. Walshe, M.D. Second edition. 8vo. Lon[illegible]

fistula exerts a salutary influence over the phthisis, I believe is the general impression of the medical profession. Yet I am not able to furnish you any valuable personal experience on the subject, never having met with the complication but twice in the whole course of thirty-two years' practice. In one of these cases both diseases were cured, the fistula first; in the other both diseases continued unto the death. Yet the well-known irregularity of the bowels in phthisis, the relaxing influence of diarrhœa and the alternate irritation of constipation, would seem necessarily to conduce more than ordinarily to anal ulceration; but the idea of any beneficial influence from this, or from any other intestinal irritation, in the treatment of a disease in which so much depends upon the condition of the digestive functions as phthisis does, is unexplained, and I think inexplicable. If the revulsive influence of a counter-irritant were necessary, I should prefer to establish it upon any other part of the body," etc.

Statistics.—With regard to the question of the frequent or the infrequent occurrence of anal fistula with phthisis, I will cite Mr. Allingham, of St. Mark's Hospital, London, who, in a very able article on "Fistula in Conjunction with Phthisis," says: "For my own part, I am quite convinced that a very considerable percentage of fistulous patients have more or less tubercular lung affection. I have endeavored to find out what the percentage is, and have carefully gone over a period of nine years in private practice, from 1871 to 1880, and find that, out of 1,632 cases of fistula seen by me during that period, 234 had phthisis, either active or latent."[1]

According to an estimate I myself made in 1860, with special reference to this very question, I found that, out of nine hundred and sixty cases of anal fistula which came under my immediate observation during a practice of nineteen years, that is, from 1841 to 1860, seventy-three cases were accompanied by well-marked phthisis in its several stages, from its inceptive to its advanced or confirmed stage. The anal fistula in fifty-five of these cases seemed evidently to have been the result of the phthisis. It may be remarked that the discrepancy with regard to the ratio of such cases, which has been noticed, may perhaps be owing to the fact that those surgeons who treat the diseases of the rectum as a specialty are more apt to see more of them, and notice them more particularly, than the general practitioner, or those who have declared that they have seldom seen them.

The relation between anal fistula and phthisis.—The next question is: Is there any relation or connection between fistula in ano and phthisis pulmonalis when these two diseases coexist in the same patient, and, if so, can it be explained? Some authors maintain, as I have already shown, that no such connection exists between them; and, if there is such, they deem it inexplicable. Now, that there is such a relation or connection between the two diseases, when thus associated, is a point in pathology which may be easily traced, explained, and established. It is well known that there is a large amount of the cellular membrane which invests the inferior extremity of the rectum; that this tissue in this vicinity has a large number of veins; that these veins, in the advanced stage of phthisis, can have but little adventitious support, in consequence of the great absorption of fat in such cases, the emaciation of which is always strongly marked in the adipose cellular membrane and muscles. Tubercular deposits in the lungs, too, must in a greater or less degree interfere with the return of the blood from the veins; and the constant impulse communicated to the anal region by coughing must also greatly tend to the production of anal abscess and anal fistula. Indeed, disease of the lungs, and especially tubercular degeneration, is that which most commonly gives rise to abscess and fistula of the anus; and this may also be accounted for by the well-known tendency which exists to ulceration of the intestines in phthisis, or to retarded venous circulation, as already stated. From these several considerations, and the proneness to suppuration in the cellular tissue of the rectum, we can at once account for the connection, as well as the frequent occurrence and concurrence of these diseases with phthisis pulmonalis.

Are anal fistulæ natural emunctories?—I will now quote the opinions of some distinguished authors who consider anal fistulæ, when coexistent with phthisis pulmonalis, as natural emunctories, and therefore should not be treated or interfered with in any way, but let alone, believing that these two diseases are in sympathy and have a mutual dependence upon each other. As a proof of this they say that when the fistula first forms the lungs are always at once relieved. The phthisis is immediately suspended in its destructive course, and as long as the fistula keeps open and continues to discharge freely so long is the patient respited. When these authors speak of an operation in these cases they mean the knife operation.

M. Velpeau says: "Experience proscribes the performance of the operation for fistula in ano in consumptive patients, first, because in most instances the fistula moderates the progress of the pulmonary disease; second, because it is usually caused by the ulceration of one of the thousand tubercles with which all the organs are then cribbled; third, because the wound rarely heals up, but suppurates abundantly, and reacts in an injurious manner upon the ensemble of the organism; and, fourth, because if by chance it closes up, it is remarked that the pulmonary affection, which was momentarily suspended, rarely fails to become thereby aggravated."[2]

Dr. Bushe says: "From what we have said when treating of stercoraceous abscesses, it is very apparent that a great many of them depend upon disease of the lungs; therefore, when they degenerate into fistulæ we should not operate on them, else their healing will give rise to an increase of the pulmonary disorder and curtail life. There are also other sympathetic fistulæ which it would be improper to meddle with, as those depending upon disease of the uterus and spine, as well as those which occur in the last stages of other organic diseases."[3]

M. Ribes observes, in his inimitable essay, that, according to his experience as well as that of others, the fistula in ano in phthisical subjects should remain undisturbed, and that it is not only useless, but even dangerous, to subject such patients to the operation.[4]

Sir Astley Cooper says: "Often, before a person perishes from phthisis he has a fistula in ano, and this is the reason fistula is considered as a dangerous disease, although in reality it is not so, but it is the consequence of the more important diseases which destroy life. The surgeon often brings discredit upon himself by operating in these cases in the last stage of phthisis, when no operation ought to be performed and when it is impossible the disease can be cured; therefore that death, which is the result of pulmonary disease, is falsely attributed to the fistula in ano."[4]

Mr. Colles says: "Are there any circumstances, general or local, that should deter us from venturing on relieving a fistulous patient, who is also suffering from phthisis, by the knife operation? There are both. I mentioned to you that experience proved, in particular instances of fistula in ano, a connection or sympathy between the local disease and grave pulmonary affections; now, if you meet a case of this kind, never attempt to operate if you find on inquiry that the patient had a chest affection for some time, that there came on the local complaint about the rectum, and that on its appear-

ance the other complaints were relieved; any operation that you perform for that man's fistula would hasten his death."[1]

M. Lisfranc is of opinion that it is very improper to operate for anal abscess or for anal fistula in phthisical subjects, for that death from phthisis in all probability will succeed the cure. He further states that he has often seen natural emunctories prolong the life of phthisical patients for a greater length of time than those established by art.[2]

It will be perceived, from the very able and distinguished authors I have presented—and many more might be named—that they fully confirm the popular prevailing opinion in the profession, that anal fistulæ, when associated with phthisis, are considered as natural emunctories and highly beneficial to the lungs; and that it is not at all justifiable to attempt the treatment or the cure of the fistulæ in patients suffering from phthisis, or in those predisposed to it.

It was this theory that induced the celebrated Baron Heurteloup, of Paris, a number of years ago, to believe that artificial fistulous drains or exutories would be equally as beneficial to consumptives as the spontaneous or natural ones represented by the fistulæ; and it was this belief that caused him to practise, at the Hôpital de la Charité, the operation of establishing artificial fistulæ in tuberculous patients in whom no anal fistulæ existed. This practice in his hands, however, met with no success; the derivative effect of the anal irritation made no decided impression upon the lungs. Those, however, who believe in the beneficial effects of the natural fistulæ in phthisical patients, do not admit that artificial substitutes will ever answer any good purpose. The benefit, however, resulting from the establishment of an artificial drain does not depend upon the large quantity of the discharge, but upon the degree of irritation that is caused and kept up upon the surface; hence, in my opinion, artificial drains are much better than the natural ones, so called, as they are completely under control and may be located and regulated exactly to suit the nature of the case. Had Baron Heurteloup established an exutory upon the chest instead of a seton in the anus of his phthisical patients, he might have benefited them more. It is strange that any intelligent physician would ever think of establishing a drain in the anal region to relieve phthisis.

The plausible theory that an anal fistula is salutary, and a derivative remedy in phthisis and must be let alone, as contended for by authorities, is, in my opinion, a serious error, and has proved so in numerous instances. It is true, I have seen patients in the advanced stage of phthisis apparently benefited on the first appearance of an anal fistula; they were unexpectedly, as it were, restored to better health, and their pulmonary affection became quiescent for the time being; but the improvement proved not to be permanent; it did not last long; the discharge from the fistula either continued to increase, or it dried up, and the patients, sooner or later, sunk. As a general rule, anal fistulæ greatly aggravate the pulmonary affection by impairing the constitutional powers, especially if attended by a copious discharge of pus and much irritation. The principal indication in all such cases is to build up, not to deplete.

I have never seen a case of phthisis, in any stage, cured by a fistula in ano, or even the life of such prolonged to any length of time, and, according to my experience, it never does any permanent good in any instance. All such cases, therefore, should have the advantage which a proper and judicious treatment offers, recollecting that an anal fistula may more frequently be the primary cause of phthisis than the cure or the mitigation of it. I have yet to see the first bad results from attempts at curing both diseases in such patients by proper treatment. It is true that in all cases in which the fistula appears in the last stage of phthisis, which is not uncommon, when all hope of the patient's recovery is gone, it would be improper, as well as useless, to attempt its cure, if, indeed, it could then be done; that is, if a phthisical patient with an anal fistula, in whom the phthisis has made rapid and serious inroads upon the respiratory organs—especially if attended by hectic irritation, profuse sweats, cough, colliquative diarrhœa, etc., and the fistula not painful, distressing, nor discharging too freely—no prudent surgeon would institute such operative proceedings for the treatment of the fistula that would in the least be calculated to shock the nervous system and to impose an additional burden upon the vital functions.

Differential diagnosis.—Some of the diseases of the pelvic region, especially anal abscess and anal fistula, sometimes produce, in weak and emaciated subjects, hectic fever, night sweats, cough, expectoration, and great physical and mental depression. Such cases are sometimes diagnosticated as phthisis by superficial observers, when no organic disease of the lungs really exists. In such the anal fistula is let alone, and allowed to reduce the vital powers of the patient by keeping up a copious and constant drain upon the vascular system, and a continued irritation of the nervous system, respectively; so that in course of time the lungs also become seriously affected, and death is sooner or later the result. This is no imaginary occurrence, as I could here report several such cases that came under my own observation.

Bronchitis.—Chronic bronchial catarrh sometimes simulates tuberculous phthisis so closely that it is well calculated to deceive, especially if attended, as it sometimes is, by persistent cough, expectoration, loss of color and strength, shortness of breath, and in some cases even hectic fever, night sweats, and diarrhœa. I have treated successfully a number of cases of anal fistula associated with chronic catarrh of the bronchiæ, which had been previously pronounced confirmed phthisis, and all treatment of the fistula interdicted on penalty of speedy death from phthisis.

Tuberculous disease of the rectum.—It is said that tubercles in the lungs are essential to their existence in other organs—that is, that they are always developed in the lungs first. But this is not always so, for I myself have, in several instances, found them, or what are commonly called tubercles, in the glands of the rectum when their existence could not be diagnosticated in the lungs. They seemed in these instances to have been developed in the glands of the rectum first. As a general rule, however, whenever they are developed in any one organ, they invade all others: doubtless originating in the lungs in the majority of instances.

Tuberculous degeneration of the rectum requires prompt and energetic treatment, or it will speedily result in ulceration and fistula; and it is the disease commonly called consumption of the bowels, and often attended by many of the symptoms of tubercular phthisis—which it very much simulates and in which it ultimately terminates unless timely arrested. Here the disease originates in the rectum, but subsequently terminates in the lungs, the rectal disease being the primary affection. On the contrary, however, it is well known that in protracted phthisis the rectum becomes greatly attenuated, all its coats being thinned and wasted, and sooner or later diarrhœa sets in, and patches of ulceration of the mucous membrane take place. These ulcers vary in form and size, being mostly circular depressions in the mucous membrane and not large; when they occur low down, between the internal and external sphincters of the anus, they are almost certain to result in abscess and fistula. These ulcerations in the rectum are by no means uncommon in phthisical subjects, and are, with their concomitants abscess and fistula, one of the complications of phthisis. Here the primary disease is phthisis, and the ulceration, the abscess, or the fistula, whichever obtains,

[1] [illegible]
Pg. [illegible]
[2] [illegible]

is the effect or the consequence of it. This plainly shows the connection between the two diseases.

There are, however, other ulcerations of the rectum almost identical in character with those already described, which are independent of phthisis, being the result of other chronic affections, as the ulcers which are known to occur in the last stages of low fevers, in chronic dysentery and diarrhœa, or in persons of a lax, lymphatic, and scrofulous constitution. Such ulcers, if not cured, are liable sooner or later to result in abscess and fistula in ano, and ultimately in phthisis in those predisposed to it.

Treatment.—Now, the most important and practical point for the surgeon to consider in this controversial affair is not whether anal fistula and phthisis are seldom or often found in the same patient, or whether, when thus found, there is an intimate or no connection between the two diseases; but it is whether anal fistulæ, when found in phthisical patients, should be let alone or treated, and if treated, by what method. These are the important points.

Before treating a case of fistula in ano, the surgeon should never neglect to ascertain to a certainty whether or not pulmonary disease is present in the case. If phthisis or a strong predisposition to it exists, which a careful physical exploration of the chest will always disclose, the treatment, if any, must be regulated to suit the case.

It is an established canon of surgery that, in order to cure an anal fistula, it must be cut—that is, divided with the bistoury; and it is also equally a law of surgery that when an anal fistula is complicated with phthisis it must not be cut, but let alone.

In accordance with the theory of non-treatment in such cases, the patient is advised not to have anything done for the fistula, as any interference with it, or the cure of it, would only accelerate the pulmonary affection and hasten his death. It is strange, passing strange, that with the abundant resources of the present advanced stage of surgery all surgical treatment of the anal fistula in such cases should be proscribed. I readily admit that to attempt to cure such cases by the knife operation would be highly improper, and it was doubtless in reference to this operation alone that this opinion was first advanced, and not to other proper and judicious surgical measures, of which there are certainly such.

The practice of the non-treatment in the cases under consideration, as advocated by the authors I have cited, and by others equally distinguished, is, however, happily and surely becoming antiquated. There is not one good reason to be urged in its favor, except in those cases in the last stage of phthisis. The views of authors generally upon this subject are anything but clear and sagacious; although able and highly distinguished, as they most certainly are, they too often allow themselves to adopt certain fanciful theories of disease, and strive too much to confine nature within definite bounds and arithmetical calculations.

In the several cases of phthisis I have named, which are at all proper for surgical treatment of the fistula, I prefer the operation by ligature to that by the knife; it has never been productive of any injury in my hands, but, on the contrary, in producing the most happy results, as I could, had I the space, illustrate this article by a large number of well-authenticated cases. I am therefore decidedly of the opinion that if any surgical operation for the fistula be adopted, it should not be by the knife, but by the ligature; for the method by the ligature is much safer and judicious, for if it does not tend to cure the phthisis, it does not at least accelerate its progress; whereas the method by knife in such cases must prove injurious in the highest degree, both in its present and future consequences. We are therefore neither justified nor warranted, by either experience or reason, in operating with the knife in such cases.

The knife operation requires the patient to be placed under anæsthesia, which is contra-indicated in phthisis; it also requires the patient to be confined to his bed and his room for a longer or shorter period; whereas when the ligature is employed no confinement is required; he can be up and about and in the open air all the time. This is of the greatest importance in the treatment of phthisical patients.

The ligature, if properly employed, does not cut or divide the fistulous sinus at once as the knife does, but it works its way through the tissues by a process of ulceration and suppuration, and not by a cutting process; indeed, it does not cut at all in the sense of the knife operation. It must be admitted, too, that the process is a healthy one, by all who understand the *modus operandi* of it and that of setons and issues. I have had abundant evidence, both from clinical observation and physiological experiment, of its great utility in the particular cases I have mentioned.

In operating by the ligature, the tightening should be effected by twisting instead of by a knot, for a knot cannot be regulated nicely or exactly; it is either made too tight and causes too much irritation and pain, or it is not made tight enough and does not succeed well. The process, too, of tying the knot frequently is attended with trouble and with pain; whereas the daily twisting of the ligature is easily made and exactly regulated, so as not to be too tight and painful, yet at the same time quite efficient.

I never hesitate to operate by the ligature in these cases, unless the lung affection is very far advanced; and even in such cases no harm to the chest difficulty will result from the ligature properly employed, or used as a seton. But in extreme cases the fistula should not be laid open, either by the ligature or by the knife, for if this is done the divided parts might not heal, and the patient left in a much more miserable condition than before, especially if he was suffering from diarrhœa. By the use of the ligature, however, this serious mistake need never occur, for the process of tightening must be conducted slowly, as a test, so that if granulation and healing did not promptly follow in the wake of the ligature, which can easily be ascertained from time to time, the tightening of the ligature could at once be stopped, and the continuity of the sphincter ani and parts preserved, the ligature either being removed or used as a seton. Indeed, if the surgeon should find, by the slow use of the ligature in such a case, that the sinus was not filling up and healing, and the patient not improving, but getting worse, he could at any time stop its use without doing any harm whatever. This cannot be done when the knife is used.

Blindness and Fecundity.—It has been asserted by Magnus, Fuchs, and others, that children, one or both of whose parents may be blind, are very liable to be themselves blind. Magnus investigated fourteen instances of married couples in whom one or both were born blind, or became blind at an early age, and found that, out of thirty-four children begotten of these marriages, eight, or 23.5 per cent., were either blind or weak-sighted. Mr. Simeon Snell reports, in the *British Medical Journal* of August 7, 1886, thirteen instances of marriages, one or both the contracting parties being blind, in which none of the children had any trouble with the sight nor any trouble with the eyes. He noticed one curious fact, however, and that was the small proportion of births. There were ten men with sighted wives, and excluding one whose wife had ceased to bear children before his blindness came on, there were left nine, with twenty-six children between them, or less than three per family. Adding to this number three blind couples with two children, there was a total of twelve with twenty-eight children, or two and one-third per family. It would almost seem, therefore, that such marriages are less than usually fruitful. Farr placed the number of children per wife in England as 5.2.

IS ELECTROLYSIS A FAILURE IN THE TREATMENT OF URETHRAL STRICTURE?

BY ROBERT NEWMAN, M.D.

THE electrolytic action (electrolysis) of a galvanic current on animal tissue is an undisputed chemical fact. Its application in the treatment of urethral strictures, practised by me for the past eighteen years, has been recognized almost universally, and followers of my method report success in thousands of cases. Good results have been reported by eminent medical men, *e.g.*, Belfield, Hutchinson, Farrand, R. Morris, Prince, Frank, Glass, Martin, and a number of others. We may add to these recent reports of distinguished surgeons of London, for example, W. E. Steavenson and W. Bruce Clark. A method so favorably spoken of naturally had many imitators, and it is not surprising that amongst these were many medical men illy prepared to do the operation successfully and totally ignorant of the proper procedure; their dominating idea being that any electrical instrument, used in any arbitrary manner, ought to give brilliant results, and failing in accomplishing these, they condemn and ridicule all reported cures by expert and careful operators.

In former papers on this subject I have tried to point out that failure in the cure of any given urethral stricture by galvanism was due to a number of causes, among the most frequent of which were the following: 1, Incompetence of operator; 2, mismanagement of the whole case; 3, wrong diagnosis; 4, faulty instruments.

I. *Incompetence of operator.*—To succeed, the operator must be an accomplished surgeon and electrician, knowing the difference between a galvanic and an induced current, in the first place; and, secondly, having some knowledge of the different results obtained by each current on animal tissue. An accomplished surgeon must he be, so as to be able to lightly introduce instruments into a diseased urethral canal and safely guide them through all parts of an abnormal or pathological passage.

The science of electricity belongs to the elementary course taught in our literary schools, and every student of medicine is expected to know all about the different actions of divers batteries. No one is competent to discuss what electrolysis might do and what it might not do unless he can tell an induced current from a galvanic circuit. Alas! how many of our medical men know when either current is indicated in the treatment of any disease requiring electricity? Hear what a professor of medicine in a provincial town says:

"Our students do not need and *would not understand* the higher and special branches of medicine, for they have no preliminary education. They come from their villages, some direct from the ploughshare; they go back again to their villages, where it is sufficient to treat fevers, zymotic diseases, bowel complaints, and to manage confinements. These branches they are taught, and if they need more let them come to us for consultations and operations."

This is one reason why many medical men look upon the treatment of disease by electricity as a sort of charlatanism—they do not know what it is because they have not been taught it at their schools. Now, do our best medical colleges in large cities give their students any better chance? I am not aware that any college has ever appointed a professor to the chair of electrical therapeutics, or that even electrolysis has been practically taught anywhere. As a curious fact I may mention, however, that the only professor of surgical electricity can be found in the Homœopathic College, in New York.

I will append the gist of a few letters that reach me almost daily, in support of my statement that the greater part of our profession are in ignorance of the uses, and even of the definition, of electrical currents.

Letter 1 asks: "How many cells shall I use of an eighteen-cell Kidder battery for *curing* stricture of the urethra by electrolysis, and how apply the bougies?"

Letter 2 writes: "How many cells of the battery do you generally use, and what size of a bougie?"

Letter 3 wants to know if the gravity battery is not best, and if he may use as an electrode a *rubber* catheter.

Letter 4 insists on using an electrical machine *to turn with a crank*, and as his two hands are engaged thereby, thinks one pole in the urethra is sufficient, asking, of *what use is the positive pole*, when the negative does the work?

Letter 5 reports that he has used such strong currents, that the patient *screamed with pain*, and notwithstanding the result was not satisfactory.

Some of these would-be operators do not even moisten the sponge, others *oil* their electrodes. I am surprised that even a reputable text-book on electricity advises to use the *positive* pole at the seat of the stricture, which must inevitably ruin the patient's urethra.

In my former articles, the modus operandi, how to use the galvanic current, the application of the poles, the strength of current, the duration of the séance, the intervals of application, and all minutiæ have been so exactly described that such ludicrous questions not only show the ignorance of the inquirer, but prove that he has not even intelligently read my articles. He has simply understood, in a misty way, that electricity can be used for curing strictures, and being disappointed at his want of success insists that the method is a delusion and a snare.

I cannot refrain here from mentioning a letter just received by a gentleman in Canada, who has studied electricity and its application in medicine and strictures.

He writes: "I meet with a great deal of scepticism and ridicule from my professional brethren. A professor in a medical college here walked up to me in a drug store and ridiculed my attempt to electrolyze some enlarged glands of the neck in a young man, and flauntingly offered to *bet* me $50 to $5 that I could not cure him, or do him any good. Nevertheless the neck is improving markedly. A professor of therapeutics argued with me that all batteries were alike, and the little old-fashioned crank-machine as good as any, but that they all did more harm than good. The professor of medical jurisprudence took a case away from me, telling the patient that electricity would do more harm than good. The professor of surgery asked me how I knew that destruction of tissue takes place in electrolysis," etc.

This ignorance and blind opposition is not only confined to teachers of medicine in Canada, but, in the face of daily accumulating facts, there are men in high standing in the United States who oppose the progress of electrolysis with an obstinate ardor that borders on vindictiveness. Thus we see the first cause of failure: "Incompetence of the operator."

II. *Mismanagement.*—Others, though having enough knowledge of the subject, will fail on account of carelessness: they do not give time to the details, are without any perseverance, and easily become discouraged if their first trials do not give them a perfect result. The following extract is from the letter of a prominent physician:

"April 10, 1885.—Assisted by Dr. B., who loaned me his battery, I pass a No. 0 (English) electrode through the stricture, but the patient was unable to bear the pain, even with only six or seven cells. Ether was administered, and with eleven cells I passed a No. 9 steel sound into the bladder.

"April 12th.—Passed a No. 8 (English) sound, this made the stricture bleed.

"April 13th.—Patient complained of chills and fever; ordered quinine. (N. B.—This was an attack of urethral fever, which passed away in a few days.)

"May 12th.—While absent from the city patient had an attack of retention, which was relieved by a catheter.

"May 22d.—Passed a No. 8 sound, much to patient's surprise. The stricture bled again.

"May 23d.—Electrolysis with ether as before. No. 10 was passed into the bladder, but only after the steady use of twelve cells for a long time.

"May 28th.—Passed No. 10 English catheter, drew off urine, followed by another chill.

"May 29th.—Still experiences some pain on micturition."

The doctor, in treating the foregoing case, violated nearly every rule which would lead to success.

First, he passed an electrode which gave pain; pain should not be given under any circumstances. If soreness is already present this is to be removed by appropriate remedies.

Second, he did wrong to give an anæsthetic, which follows from the foregoing—where there is no pain an anæsthetic is not required. The patient should be able to express his feeling as a partial guide to the operator.

Third, the current used was entirely too strong in this case. Eleven cells may be used perhaps in exceptional cases, where the battery fluid is weak and cells and elements small. Six cells would have been fully sufficient.

Fourth, more than one electrode was passed at a single sitting. The invariable rule is that no two instruments should be passed, even for several days after the operation.

Fifth, two days later an English sound was passed, making the stricture bleed, which showed that damage was being done to the urethra. Why No. 8 was selected after No. 9 had passed two days previously I cannot understand. The object is to enlarge the calibre of the urethra, during each subsequent sitting. This treatment also brought on two attacks of urethral fever, which will never happen with proper care.

Sixth, instead of allaying pain and irritation the doctor made matters worse, by using the sound and producing more irritation.

Notwithstanding all this mismanagement the patient and doctor were pleased with the improvement. One year later the operator wrote me, however, that the case did not turn out as well as he could have wished. He acknowledged his errors and reported other more successful cases.

I will conclude this article with some rules, as a safe guide for practitioners who wish to adopt the treatment of electrolysis in stricture of the urethra, which will also serve as answers to numerous questions received from correspondents.

1. Any good galvanic battery will do which has small elements and is steady; the twenty-cell Drescher battery, carbon and zinc, is an excellent instrument, sufficient, particularly, for the beginner.

2. The fluid for the battery ought not to be used too strong.

3. Auxiliary instruments, as galvanometer, etc., are important to the expert, but not necessary for the beginner.

4. For the positive pole a carbon electrode is used, covered with sponge, moistened with hot water, and held firmly against the cutaneous surface of the patient's hand, thigh, or abdomen.

5. For the absorption of the stricture the *negative* pole must be used.

6. Electrode bougies are firm sounds insulated with a hard-baked mass of rubber; the point is a metal bulb, egg-shaped, which is the acting part in contact with the stricture.

7. The curve of the bougie is short; large curves are mistakes.

8. The plates must be immersed in the fluid before the electrodes are placed on the patient, and raised again after the electrodes have been removed.

9. All operations must begin and end, while the battery is at zero, increasing and decreasing the current slowly and gradually by one cell at a time, avoiding any shock to the patient.

10. Before operating, the susceptibility of the patient to the electric current should be ascertained.

11. The problem is to absorb the stricture, not to cauterize, burn, or destroy tissues.

12. *Weak currents at long intervals.*

13. In most cases a current of six cells, or from two and a half to five milliampères, will do the work, but it must be regulated according to the work to be done.

14. The séance should be at intervals, not too frequent in succession.

15. The best position for the patient to assume during the operation is that which is most comfortable for himself and the operator. I prefer the erect posture, but the recumbent or others may be used.

16. Anæsthetics I like to avoid; I want the patient conscious, so that he can tell how he feels.

17. Force should never be used; the bougie must be guided in the most gentle way; the electricity alone must be allowed to do the work.

18. During one séance two electrodes in succession should never be used.

19. All strictures are amenable to the treatment by electrolysis.

20. Pain should never be inflicted by the use of electrolysis; therefore it should not be applied when the urethra is in an acute, or even subacute, inflammatory condition.

III. *A mistaken diagnosis* is another fruitful source of disappointment with many. It stands to reason that where no stricture is present, but some other disease of the urethral mucous membrane, and this is energetically treated with the galvanic current, no cure can result, and even some harm done. Still some have reported unfavorable to the efficiency of the current where there never was a stricture present. The following have been mistaken for stricture to my knowledge: Spasm of the bladder; the encroachment on the calibre of the urethra by an enlarged prostate; granulations and ulcers of the urethra; urethral abscesses, etc. Some tumor, neoplasm, or calculus may cause impediment to the flow of urine and be mistaken for stricture by the neophyte. Chancroidal and syphilitic conditions may still more complicate the diagnosis. I will give in brief one of these troublesome cases, which occurred in my own practice. Patient came from the South, entirely broken down, to be treated for stricture. Three were found, respectively 1 inch, 3½ inches, and 6½ inches from the meatus.

During June, 1885, his condition and general health improved under treatment. Electrolysis materially improved the two deeper-seated strictures, but the anterior one was not favorably influenced by the current, on the contrary, the induration spread toward the meatus.

July 11th.—Stricture close to meatus very much indurated, firmly matting together mucous membrane and subjacent tissues. Electrolysis was applied and succeeded in softening the tissues beyond my expectation. I was able to pass a French No. 25 well and for fifteen minutes; with six cells applied the current.

August 1st.—Stricture worse, scarcely admits No. 18 bougie, and submucous tissue hard and callous. I now put my patient on the mixed treatment, and it was astonishing to see the callous appearance vanish, and now the remaining stricture was easily removed by the current.

September 26th.—No. 26 French can easily be passed. A year later re-examination proved the complete cure.

Now I could understand why a friend of mine, who was well pleased with his results in deeper-seated strictures, kept complaining to me that he did not get favorable results whenever he treated strictures situated in the immediate neighborhood of the meatus, but that they would recontract, and sometimes become worse after treatment, notwithstanding the greater care taken and my rules literally followed. Taking into consideration that this gentleman took most of his cases from the venereal class of a hospital, the solution of the difficulty was easy in the light shed on it by my own case.

These cases are not so simple as they may seem to the readers of this paper, for in many of them no [illegible] symptoms can be discovered, nor will the patient admit, or know of, the probability of a syphilitic infection.

IV. *Faulty instruments* certainly may become a cause of failure, though an expert operator may partly overcome this cause by the skilful handling of even rude instruments. Nevertheless, a careful man will select the best instruments as an important factor to his success. A good outfit consists of: A *galvanic* battery, with conducting wires, sponge electrodes, connecting screws, bougies à boule, and a full set of electrode bougies. The latter should have a proper curve, must be smooth and well polished, and well insulated, except at the bulb. The latter, again, must have the proper size and shape. A set of tunnelled electrodes and a few auxiliary instruments complete the set.

The electrodes may be either curved or straight, the bulbs acorn- or egg-shaped. I prefer to have them with short curves. The tunnelled electrodes are of invaluable aid in strictures of small calibre, and if used properly will make false passages a fable of the past.

For a further description of the instruments used by me, and the modus operandi, I refer to my former articles, particularly to THE MEDICAL RECORD of August 12 and 19, 1882, and to [illegible] of January 3, 1885. The question asked so frequently as to the number of cells used cannot be answered more definitely than the dose of morphine to be given in different diseases can be answered by any one dose. The operator must select the strength of the current for each individual case.

It would certainly be desirable to express the quantity of electricity in positive numbers, but at present we have not yet uniform and reliable galvanometers. While I advise weak currents of about six cells, this measure does not express a fixed quantity, and at best is only relatively correct. The amount of electricity to be used depends partly on the work to be done, and also on the nature of the stricture. In the practical application other facts must also be considered; for example, the state of the atmosphere, whether it be humid or dry, exercises great influence on the current. In clear, dry weather six cells may do the work for which on an unfavorable day ten or more cells would have to be used. Even if we had a universal system of measuring our currents it would not be of any practical benefit in these cases, for the exact amount a patient could endure would have to be determined afresh at every sitting by the operator, for the patient will sometimes bear much less at times, and then, again, he will not be affected by a much stronger current.

There may be other reasons of failure, but I have already touched on so many that other causes will easily suggest themselves to an intelligent surgeon.

To judge from the many causes which might operate to produce failure in this treatment, it may seem very difficult to produce many good results. Such, however, is not the case, and with care and good management failures are the exception. All depends, as in every other operation, upon the skill and the talent that is brought to bear upon each case. In support of this let me cite a short report by a physician. He writes from Rockaway, N. J.:

"A gentleman came to me suffering from chills, following the repeated trial of passing an impervious stricture by Professor N——. He said the doctor had failed to pass any instrument whatever into the bladder, and had that day given up in disgust. I proposed electricity. He consented, and on examination I found three strictures, located deep in the urethra, two-thirds the distance to the bladder. The first sitting was prolonged to twenty minutes, a No. 8 acorn-shaped bougie being used at the seat of the stricture. I did not succeed in engaging it. One week later the seance was repeated in the same manner; did not succeed in passing to bladder. Two weeks later I used a straight tip in place of the acorn-shaped one, and succeeded in passing this through a corkscrew-shaped stricture one and three-eighths of an inch in length. At the next seance I passed readily a No. 10 bulb, acorn-shaped. Since then I have succeeded in obliterating it to such an extent that I can scarcely feel any constriction on passing the instrument. Patient has never had a chill or any untoward symptoms after any of the sittings."

The case speaks for itself. Here a professor, whose skill in using instruments is undoubted, was unable, at nine trials, to pass any instrument into the bladder, and acknowledged his incapacity to do it. By the aid of electrolysis another doctor, probably not as skilled in the manipulation of instruments in the urethra, succeeds.

Now, in conclusion, electrolysis of urethral strictures *must* and *will* succeed, in proper hands, in every case that is intelligently and judiciously undertaken. The operation itself needs a clear head, a steady hand, fingers which both see and feel, patience, and good discrimination in the application of the strength of current and length of sitting. In the strictest sense of the word, there *can be no failures* in dissolving away the dense tissue that constitutes a stricture, for electrolysis is based upon a fixed chemical action of the constant current on these animal tissues. Electrolysis cannot fail, but operators may, and do.

[illegible] AND MALARIAL GERM.

[illegible] M.D. [illegible]

As the attention of the medical profession has been recently directed toward the supposed parasitic origin of malarial fevers, no apology is necessary for this paper.

Patient No. 1,753 was admitted into the Post Hospital at Columbus Barracks, O., August 16, 1886. The patient was a negro man, aged twenty-six. He had been employed for the past two years as a cook, most of the time on board a boat which plied between Cairo and St. Louis.

When admitted into hospital he was suffering from a well-marked chill, which was followed by fever and sweating. The diagnosis of tertian intermittent fever was made. No quinia was administered, but the fever was subdued by antipyrin and acidulated drinks, and the bowels moved by a dose of calomel, sodium bicarbonate, and rhubarb, five grains each.

On August 17th the patient had a slight rise of temperature about the hour at which he had had the chill on the previous day.

On August 18th, about half an hour earlier than on August 16th, the patient had a severe chill, and during the paroxysm three specimens of his blood were taken and immediately placed under the microscope. These specimens were prepared in the following manner, suggested to me by Dr. Kinsman, of Columbus, O. The glass slides and thin covers were first carfully cleansed in water acidulated with hydrochloric acid, and then washed in stronger alcohol. A thin ring of pure vaseline was made on the slide. The diameter of the ring was somewhat smaller than that of the circular glass cover. A finger of the patient's right hand was carefully cleansed with stronger alcohol, which was allowed to evaporate. Then a narrow rubber band was placed tightly around the finger, about an inch from its extremity. A slight prick of the lancet in the finger's end was followed by the appearance of a small drop of blood. A glass cover was applied to the surface of the drop without touching the finger, and immediately placed over the vaseline ring on the slide in such a manner as to have the blood dropped adhering to the cover within the ring.

On placing one of the specimens under a one-eighth inch objective the following bodies were observed: Nu

merous red and some white blood-corpuscles, and several almost transparent bodies about the size of the red corpuscles. These bodies seemed to be surrounded by a membrane less transparent than its contents and presented the following appearances: These were at first globular and contained a few dots, which were in motion among themselves. At the end of two minutes they had assumed an oval shape, still containing dots, and two minutes later they had assumed the appearance of slightly curved, short cylinders, containing a few dots. Several similar bodies were observed later, which assumed a more fixed globular shape, and did not become cylindrical. Other bodies were observed which contained dots and had several thread-like bodies attached to them. These were longer on one side than on any other. These bodies moved in their entirety; their dots moved among themselves, and there appeared to be a waving movement among the transparent filaments.

This last-described body ultimately got near enough to a red blood-corpuscle to apparently touch it with its longer filaments, and then all of its movements ceased. These bodies were observed by Major Charles R. Greenleaf, Surgeon U.S.A., as well as by me. A careful examination, five or six hours after the one recorded, failed to demonstrate these bodies to Dr. Kinsman, Dr. Greenleaf, and myself. It should be stated, however, that the blood had thoroughly coagulated before this examination was made.

The administration of quinia in full doses soon removed all malarial symptoms; and after the administration of the quinia no more bodies of the kind described were observed.

Clinical Department.

OPERATION FOR HARE-LIP SUCCESSFULLY PERFORMED UNDER COCAINE.

Dr. A. H. Goelet, of 243 West Fifty-fourth Street, reports the following: Miss Mary N——, eighteen years of age, had a shallow though very disfiguring cleft in the right side of her upper lip, which she desired to have corrected by operation. It was decided to use cocaine, although the patient was timid and sceptical in regard to the full anæsthetic properties of the drug. Assisted by Drs. Cutler and Kinch the writer performed the operation on July 7th. One assistant compressed the coronary artery between his thumb and finger at either angle of the mouth, and the cocaine was injected hypodermatically in the vermilion border on either side of the notch, ℥viij. being used on each side, and the operation was commenced within two minutes. The lip was transfixed near the border on the left side of the notch, and the incision carried to the apex of the cleft. The same was done on the opposite side, and the flaps drawn down. The projection being too great at the margin of the lip, the flap was cut obliquely through, a small piece removed, and the coaptation was made perfect. The whole was neatly sewed with fine iron dyed silk which had been sublimated in a solution of 1 to 1,000. One hare-lip pin was introduced near the vermilion border, the wound dusted with iodoform and sealed with flexible collodion. Over this were placed several layers of antiseptic absorbent gauze, which was held in place by a strip of rubber adhesive plaster from one cheek to the other.

The pin was removed on the third day and the other sutures on the fifth day, when union was found to be perfect and complete. There was very little œdema.

The patient experienced no pain during any step of the operation (which occupied nearly three quarters of an hour) except that occasioned by the prick of the hypodermatic needle. A sponge was placed in the mouth and with the co-operation of the patient, who kept it pressed against the front teeth, the blood was prevented from reaching the throat.

Those who have experienced the difficulties of this operation under ether will readily appreciate the advantages of this method, which insures perfect quiet and the co-operation of the patient.

The projection at the margin of the lip which was intentionally left at the time of the operation has now disappeared and the result is perfect.

FAILURE OF LARGE DOSES OF ANTIPYRIN IN A CASE OF SUNSTROKE.

Dr. M. Singer, house surgeon of St. Mary's Infirmary, Galveston, Texas, reports the following case: "A man, name unknown, aged about forty, was brought to St. Mary's Infirmary on August 5, 1886, at 6 P.M. At about three o'clock in the afternoon he had been found lying unconscious in the street by a police officer who, supposing him to be drunk, took him to jail. Two hours later the jailer, noticing the deep coma and intense bodily heat, had him conveyed to the hospital. Upon admission the pulse was 120, full and strong; respiration, 40, stertorous, with short intermissions about every five minutes; temperature, 108.4°. Skin hot, dry, and parched; coma complete; pupils slightly contracted. I gave fifty grains of antipyrin under the skin, applied sinapisms to extremities, and ice on the head. At 7 P.M. the patient's condition was unchanged, every symptom as before. Gave ten grains of antipyrin under the skin.

"At 8 P.M. the patient's general condition remained the same, except that he had passed his water in bed. Pulse, 122; temperature, 108.8°. Gave hypodermic, twenty grains of antipyrin. At 9.30 P.M. symptoms unchanged, except for the temperature, which now was 109.8°. The excessive heat of skin could well be felt through the patient's shirt and the bed sheet. Gave hypodermic, twenty grains of antipyrin.

"At 11 P.M. pulse 140, weak; temperature, 109.8°; respiration 18, stertorous, puffy, sometimes catching and irregular.

"Patient died at 11.30 P.M. Temperature at time of death, 110°; post-mortem temperature taken three-quarters of an hour after death, 108.5°; pupils slightly dilated. The temperature in this case was taken in the axilla. No other antipyretic measures were employed but those metioned above. I have used the same preparation of antipyrin in many febrile conditions, and in doses of from twenty to thirty grains, without failing at any time to reduce the fever heat. In this case, however, one hundred grains of the drug given under the skin within a period of three and a half hours proved to be utterly worthless. No diaphoresis was produced at any time after the administration of the remedy."

INTESTINAL OBSTRUCTION FROM AN UNUSUAL CAUSE.

Dr. E. T. Gould, of Sonora, Cal., writes that he was called on the morning of June 27th in consultation upon a case of obstruction of the bowels occurring in a patient fifty-eight years old. Laparatomy was advised, but as the attending physician did not concur in this it was decided to use morphine hypodermatically in sufficient doses and with sufficient frequency to produce entire freedom from pain for forty-eight hours, and then to give a full dose of castor-oil. The treatment was ineffectual and death occured on June 30th. Five hours later the autopsy was made. The cause of the obstruction was found to be strangulation of four feet of the ileum by a loop of diverticulum. The diverticulum, an inch and a half in length, was from the ileum, and its tip had become adherent to the bowel as a result of previous inflammation. It was located three feet from the ileo-cæcal junction.

POISONING FROM CORROSIVE SUBLIMATE IN OBSTETRICAL PRACTICE.

Dr. P. J. Clark, of Oakland, Neb., writes: "I have the misfortune of adding another case of intoxication from corrosive sublimate to the already long list which I see reported in The Medical Record of July 10th. On November 19, 1885, I attended a case of [illegible] labor, and delivered by podalic version. The uterus was washed out by a solution of bichloride of mercury, 1 to 1,000, and all seemed to go well until the third day, when the patient complained of considerable pain. This was quieted by morphine, and the vagina irrigated twice daily with a solution of the bichloride, 1 to 1,000. In a few days the patient complained of great pain in the abdomen, and suffered from profound depression of the nervous system and salivation. She had been very restless and could not sleep for several nights before, and now she said she was going to die. The irrigations with the solution were discontinued, and chlorate of potash was administered. In a week the woman had entirely recovered. I was very much surprised at the time, as I had never met with such an experience before and had seen no cases reported. I would not use as strong a solution again.

CIRCUMCISION UNDER COCAINE—IMPROVED OPERATION.

Dr. E. R. Palmer, Professor of Physiology in the University of Louisville, writes that, desiring to perform circumcision under cocaine, he determined to use Corning's method of sequestration. "The patient, a young man, twenty years old, with a complete congenital phimosis, was seated in a chair, and the penis was seized by my assistant and drawn upon firmly. A Martin bandage, seven-eighths of an inch wide and a yard and a half long, was next applied, the first turn being made behind the scrotum to prevent slipping, and the bandage being then wound tightly back and forth from the symphysis pubis to the corona and back again. An ordinary hypodermatic syringe was next filled with a six per cent. solution of cocaine, and the needle, directed toward the extremity of the penis, was passed at four different points through the skin over the glans, a fourth of the contents of the syringe being discharged each time into the subcutaneous tissue. No attempt was made to introduce the drug from the mucous surface. In about three minutes I began adjusting a Rogers clamp, occupying as many more minutes in getting it placed to suit me and screwed down. The prepuce was removed with one stroke of a pair of long curved scissors, and the clamp removed. The dorsal artery was found not bleeding; the frænum was not cut. The mucous membrane was split up, and some eighteen sutures leisurely introduced. The bandage was now removed and, contrary to expectation, no hemorrhage ensued. Less than a drachm of blood was lost during the entire operation. The wound was dressed loosely with absorbent cotton wet with equal parts of listerine and water. Not a twinge of pain was felt after the last needle-puncture had been made. The young man, of nervous temperament, was at first quite pale, but later assisted in the stitching, and as he washed his hands after the operation remarked that his penis still felt dead. The wound healed in forty-eight hours by first intention.

"The advantages of the bandage are several: It wholly controls bleeding, it localizes the action of the cocaine, and it increases the facility with which the penis can be handled during the operation. The reverse direction for application, that is, from behind forward, will be found the best, because the easiest, and fully effectual."

Dr. Palmer adds that he performed the operation a second time in the same manner with equally good results as regards anæsthesia. But the continuous suture was used, and although perfect coaptation was accomplished, some trouble was experienced later from swelling and from syphilitic induration of the parts. It was attempted to remove the suture but this was found impossible, and the writer thinks it would have been better had interrupted sutures been employed. The case is now doing quite well, however, and the result will be good.

THE VALUE OF DELAYED OPERATION IN MAMMARY CANCROID.

Dr. C. Deaderick, of Knoxville, Tenn., reports the following instructive case: "In May, 1878, I was called, in consultation with two other physicians, to see Mrs. E. L. M——, a lady fifty-eight years old, who had an infiltrating scirrhous cancer of the breast. The disease had been in progress about two years (she had nursed her husband a few years before, who died of cancer) and was far advanced, nearly the whole breast being involved, as well as the axillary glands on that side, which were very much enlarged. A rough ulcerated and bleeding surface, about two and a half inches in diameter, covered the most projecting portion of the tumor. The patient's general health was extremely poor. There was loss of appetite, great emaciation, nausea, and feebleness. Taking everything into consideration, the case did not seem to be a favorable one for surgical operation. There was one point upon which we all agreed, viz., that she would not live through the summer without surgical interference, but upon the matter of the propriety of a surgical operation we could not agree. The attending physician took positive ground against it. The writer took positive ground for it, and our colleague said he would sustain either one of us. This "dead lock" necessitated the calling of a fourth, Dr. J. M. Boyd, who decided with the writer. Accordingly on May 26, 1878, I, assisted by Drs. J. M. Boyd and J. P. Park, removed the whole of the diseased breast and all of the enlarged axillary glands. The prostration of the patient, after the operation was completed, was such that we thought it imprudent to remove her from the operating table for several hours.

"The wound healed promptly, but in July following a nodule, about as large as a filbert, developed near the cicatrix, and on July 23d, after freezing the parts with rhigolene spray, I removed it. Again, on August 21st I removed another small lump from near the edge of the cicatrix, but at a different point; again, on October 20th, another from a point two inches above the outer end of the cicatrix; again, on February 17, 1879, another from near the edge of the cicatrix; and finally, on May 21, 1879, another, an inch and a half above the middle part of the cicatrix.

"After that the disease seemed to be exhausted, and there was never any evidence of a return of it. After the first operation the patient's health improved very much and continued good for several years; but her constitution was always delicate, and at the time of the original operation she was prematurely old physically.

"About eighteen months ago her general health began to fail, and she died in her sixty-sixth year, August 9, 1886, of marasmus, having lived seven years two months and nineteen days after the last removal.

"Taking into consideration the general condition of the patient and the advanced condition of the disease, the result was extraordinary, and is a strong argument in favor of the knife *persistently* used in removable cancer."

THE PRAIRIE ITCH.

Dr. John F. Lockwood, of Batavia, Ill., writes that while living in Central Wisconsin he had several cases of the so-called "prairie itch," or "Michigan itch," and always succeeded in curing it by the following: Acid. sulph. dil., [illegible]

dose, a teaspoonful three times a day, half an hour before meals whenever there was any acidity. Several writers in *The Medical Age* maintain that the disease is merely a variety of scabies, and state that they have always obtained a speedy cure by the use of some form of sulphur externally applied. And Dr. Hope, in a recent number of THE MEDICAL RECORD, writes that his experience with the disease in Kansas was very similar.

CORROSIVE SUBLIMATE IN THE TREATMENT OF PURPURA HÆMORRHAGICA.

DR. R. A LANCASTER, of Gainesville, Fla, writes: "A short time since I had a patient suffering from a severe attack of purpura hæmorrhagica. There were well-marked purpura spots larger than buck-shot scattered over the body, limbs, forehead, and roof of the mouth. There was also free and persistent hemorrhage from four decayed roots of teeth on either side of upper and lower jaw. In spite of the heroic use of all the recognized hæmostatics and astringents, both internally and locally, the bleeding continued for seven days. Having tried all the remedies that I had ever heard recommended, with apparently no result, I decided to try the local application of a strong solution (1 to 240) of the bichloride of mercury.

"The mouth was well rinsed with this, and pledgets of cotton wet in the solution and applied to the bleeding surfaces.

"The bleeding was at once arrested and convalescence established. This result would seem to support the 'germ theory' of this disease. The patient was so low and so nearly bloodless that the hemorrhage may have been about to cease of its own accord, but if I should ever have another such case to treat I shall certainly give the remedy a further trial—both locally and systemically."

CONSTITUTIONAL SYMPTOMS FROM COCAINE

DR. FREDERICK S. WILLIAMS, of Puyallup, Wash. Ter., reports a case of operation for lacerated cervix uteri in which, as the patient objected to ether, cocaine was used. A pledget of absorbent cotton, saturated with a twenty per cent. solution of cocaine, was placed over the cervix, and after a time the edges of the laceration were pared without giving rise to any pain. Then four minims of the same solution were injected on each side of the wound. No pain was felt from the needle-punctures, but in about a minute and a half the patient began to speak as if with an effort, saying, "I feel as faint," and gasped as if struggling for breath. She was immediately placed on her back, with head lowered, and told to breathe deeply.

She obeyed for a few times, then recommenced her gasping, which she continued for about a minute. Then followed shallow breathing for four or five minutes, when she began to rally a little, and the breathing became gradually stronger but irregular.

Her pulse at first was very rapid, irregular, and weak, then became during most of the time of the shallow breathing almost imperceptible, gradually returning with the approaching normal respirations.

Consciousness at once was dulled, and during the period of the shallow respirations was completely lost.

At the end of about ten minutes she rallied, her pulse, respirations, and consciousness returning to their normal condition. She was then very much frightened, and asked what time it was and about her children, stating she had been asleep and felt numb all over. These symptoms were, as manifested, uninfluenced by drugs or stimulants, as none had been given, except a dose of potassium bromide at the beginning. Dr. Williams then proceeded with the operation, and introduced three stitches without any further mishap. There was very little hemorrhage from the cut surfaces. The patient stated that some of the medicated applications to the uterus had pained her more than did the operation.

CONGENITAL MALFORMATION OF THE EXTERNAL EAR.

DR. E. H. JONES, of Weyauwega, Wis., writes: "In THE MEDICAL RECORD of August 7th Dr. T. R. Williams, of Beechtree, Pa., relates a case of congenital malformation of the external ear which was very similar to one occurring in my own practice. On January 3, 1886, I delivered Mrs. F—— of a healthy male child weighing about eight pounds. The nurse calling my attention to the right ear, I found upon viewing it posteriorly it appeared to be perfect, but an anterior view revealed the fact that the meatus and folds of the cartilaginous portion were completely obliterated; the tragus was also wanting. The parts were covered by integument of the same character as that of the cheek, with the exception that two small warts were situated near the site of the closed meatus. The child has remained perfectly healthy, never having shown any symptoms of trouble arising from the closed ear."

TREATMENT OF ASPHYXIA OF THE NEWBORN.

DR. EDWARD REYNOLDS, of Boston, Mass., referring to the mode of restoration of asphyxiated infants by suspension by the heels, writes: "I wish to describe a method in which I have great confidence, which combines the advantages of this position with a most efficient and yet gentle, artificial respiration. The child lies on its back, head downward, upon the operator's forearm held nearly perpendicularly to the floor, and is retained there by his fingers, which are hooked over its shoulders. In this position the child's arms fall downward by the sides of its head, and their weight, aided by that of the thorax itself, at once draws the ribs into the position of complete expansion of the chest. If, now, the thorax be compressed against the forearm by the other hand and suddenly released a most satisfactory respiration is the result. This method, combining as it does the advantages of an afflux of blood to the brain with a most efficient artificial respiration and an easy escape of fluid from the trachea, seems to me well worthy of a more extended trial, especially as my experience with it, though not very large, has been most satisfactory."

IODOL IN OCULAR THERAPEUTICS.—Iodol is a combination of iodine and of pyrol. It is a grayish powder, containing eighty-five per cent. of iodine, and possesses the properties of iodoform without its disagreeable smell. It may be employed either as an ointment, with an equal weight of vaseline, or in alcoholic solution with glycerine. It is but very slightly soluble in water. According to M. Trousseau, in a cummunication made by him to a recent meeting of the Société de Thérapeutique, excellent results have been obtained from its employment as a pomade in cases of blepharitis with ulceration, in affections of the lachrymal passages, and in chronic conjunctivitis. On the other hand, it has but slight effect in acute conjunctivitis. The ointment is much superior to the yellow precipitate one in phlyctenular or granular conjunctivitis, and in chronic (torpid) ulcers of the cornea. In fine, iodol is superior to iodoform by its marked anæsthetic and antiseptic properties, and by its rapid influence upon the cicatrization of rebellious ulcers. —*Dublin Journal of Medical Science*, July, 1886.

Progress of Medical Science.

Peripheral Neuritis in Locomotor Ataxia.—The history of peripheral neuritis has been enriched in the past few years by numerous works which have had the effect of causing a modification of some of the views formerly held as to the pathology of tabes dorsalis, and as to the pathogeny of certain complications of this affection. MM. A. Pitres and L. Vaillard have reviewed in an article in the *Revue de Médicine* for July, 1886, a number of cases hitherto recorded, and have added a report of five coming under their own observation. From a study of these cases they are led to conclude that: 1. The peripheral nerves in tabes are often the seat of inflammatory changes. 2. Neuritis in this disease does not differ in any of its anatomical characters from other recognized forms of the non-traumatic affection. 3. The topographical distribution of this inflammation is very variable; it may affect the sensory nerves, the mixed nerves, or the visceral nerves. 4. In most cases, though not in all, it begins at the terminal extremities of the affected nerves. 5. The extent and gravity of the neuritis bear no constant relation to the duration or the extent of the medullary lesions. 6. The complication plays no part in the production of the specific symptoms of tabes, such as the lightning pains, ataxia, abolition of the patellar reflex, etc. These symptoms would seem to be due to the sclerosis of the posterior roots and of the posterior columns of the spinal cord. 7. On the other hand, certain irregular symptoms, occurring at times in locomotor ataxia, seem to have a direct causal relation to peripheral neuritis. Such are: *a*, the areas of cutaneous anæsthesia or analgesia; *b*, the trophic cutaneous affections, perforating ulcers, various eruptions, falling of the nails, etc.; *c*, certain motor paralysis, with or without muscular atrophy; *d*, arthropathies and spontaneous fractures. 8. The visceral crises occurring in locomotor ataxia are also, perhaps, in certain cases, the consequence of neuritis of the corresponding visceral nerves.

Paralysis Agitans without Shaking.—Dr. Beevor related several cases of paralysis agitans without tremor, in a paper read before the Medical Society of London. In these cases, fixed attitude, rigidity of the neck, with difficulty in looking up, expressionless countenance, slow delayed movements, difficulty in rising from the sitting posture, monotonous and mumbling speech, were present. The writing in nearly all the cases was wavy; retropulsion, apropulsion was frequently present. Charcot, Buzzard, and Gowers have published cases of this kind. It seems possible for paralysis agitans to run its course without any tremor being present.—*Birmingham Medical Review*, July, 1886.

Congenital Bilateral Dislocation of the Radius.—Dr. R. Heelis reports the following case in *The Lancet* of August 7, 1886: A boy, eight years old, was brought to him on account of trouble with the arm. Examination showed a dislocation of the left radius, which was easily reduced; but any slight motion would throw it out of place again, especially pronation. In complete flexion the dislocation was reduced: it could easily be reduced by manipulation in any position of the forearm, as the joint was so loose and there was some lateral movement possible in the humero-ulnar articulation. The right radius was partially dislocated—that is to say, only about one-fifth of the circumference of the head rotated on the external condyle of the humerus, the rest projecting behind and to the outer side of the joint. This dislocation was irreducible—at any rate, unless considerable force was employed. The external humeral condyles on both sides appeared to be unusually small, hence the difficulty of retaining the dislocated bone on the left side in position. The dislocation therefore was similar on both sides, being outward and backward. When the arms were extended there was a considerable projection on the outer and upper part of both forearms, produced partly by the outward dislocation and partly by the disproportionate development of the supinator longus. All the normal movements could be performed by both forearms, but pronation and supination, especially the latter, were very weak, and their place was usually taken by movements of flexion and extension. The patient seldom used his right arm, which was less muscular than the left. The existence of some deformity had been noticed by the parents since his first year, and even from birth. There was no history of any accident to the boy or to the mother during gestation, or at delivery, which was normal.

Tuberculosis of the Tongue.—There are two forms of lingual tuberculosis, the primary and the secondary, both of which are rare, but the former especially so. Secondary tuberculosis of the tongue is usually met with in the latter stages of pulmonary phthisis, and occurs in the form of superficial and dirty-looking ulcers, which are exceedingly painful and add greatly to the sufferings of the patient. The primary form is a very uncommon affection, or at least it is so considered, though it may be that this belief has arisen from mistakes in diagnosis, lingual tuberculosis having been regarded as carcinoma and reported as such. Dr. G. Feurer reports two cases of the disease in the *Correspondenz-Blatt für Schweizer Aerzte* of August 15, 1886, and the following description is taken from his article: The muscular tissue is very seldom the seat of tubercular disease, and this is the explanation of the freedom which the tongue enjoys, for of all muscular structures it is the one most frequently attacked. Primary lingual tuberculosis occurs usually in individuals who have acquired or inherited a predisposition to the disease, but who are as yet free from the specific lesions in other organs. In addition to a more or less characteristic, often granular, ragged, and dirty ulcer, there is a deep infiltration in the substance of the tongue. This infiltration consists of a number of more or less sharply defined nodules, the size of a millet-seed, either isolated or lying closely together. Sometimes these become agglutinated into a whitish-gray, transparent, or cloudy mass, presenting an appearance like that found sometimes in tuberculosis of the testicle. Microscopical examination shows these nodules to be tubercles with all their histological characteristics. Tubercle bacilli are also present. There may, in certain cases, be such a marked swelling of the tongue as to completely fill the mouth, showing the marks of the teeth and interfering with speech and mastication, and presenting the picture of a subacute glossitis. At times there is fever of a hectic type, and the patient's general health becomes seriously depressed. There is usually considerable pain, which is increased by attempted mastication. The pain is, however, localized, and the radiating pains, to the ear and elsewhere, such as are commonly noticed in carcinoma, are absent. This is due, the author says, to the fact that while cancer spares no tissues, but invades all, nervous as well as others, which lie in its path, tuberculosis adheres to the connective-tissue spaces and affects the other tissues only indirectly in interfering with their nutrition. The submaxillary glands are infected in tuberculosis of the tongue, but they are never enlarged to such an extent as they are in carcinoma. The disease occurs probably by direct infection through wounds of the tongue, for if the bacilli were brought through the blood-channels, they would probably be arrested in other more predisposed organs. In both of the cases observed by Dr. Feurer there had been wounds of the tongue which did not heal, and in the immediate neighborhood of which the infiltration commenced. The treatment of lingual tuberculosis consists in the early removal of the diseased foci, and of the swollen glands in the submaxillary region. The prognosis is as yet unsettled. In some cases there has been no return of the disease, after a number of years.

either in the tongue or in other organs. In one case of the author's the patient died, four months after the operation, of meningitis, apparently tubercular, though an autopsy was not made. Usually, when the lingual affection has not been removed the disease has in time attacked other organs, generally the lungs or intestines.

Potassium Permanganate in Burns and Frost-bites.—Dr. A. A. Züboff writes in a Russian journal that, having tried potassium permanganate in upward of sixty cases of burns and frost-bites, he has arrived at the following conclusions: 1. Permanganate of potash, in the shape of frequently changed compresses (linen or hygroscopic cotton-wool soaked in a solution of one or two grains to an ounce of water), is an effective remedy for frost-bite of the first and second degrees. 2. The same lotion acts as successfully in burns of the first degree. 3. It is less successful in burns of the second degree. At all events, the permanganate lotion rapidly relieves inflammation around blisters, and pain, and prevents suppuration when blisters remain intact. In this category of cases it is advisable to employ a weaker solution (half a grain, or even less, to an ounce). Two cases are given in detail. One of the patients received (when taking a vapor-bath) a scald of the first degree, extending from the breasts to the inguinal folds anteriorly, and between the same levels posteriorly. Pain disappeared within an hour after the application of the permanganate lotion. Soon the epidermis began to peel off. She was cured within eleven days. Another woman had a similar scald of the face and a hand. She also obtained rapid relief, the treatment lasting a week.—*London Medical Record*, August 16, 1886.

Inversion of Uterus with a Large Fibroid.—Dr. Goossens, of the Rotterdam Hospital, mentions, in a Dutch medical journal, an interesting case of inversion of the uterus complicated with a fibrous tumor of the wall. The woman was first admitted into the hospital in 1881, for menorrhagia which had lasted for three years, or since her last confinement. On examination, a large tumor was found in the vagina, the base being evidently within the uterus. By means of bimanual exploration, the organ was felt to be enlarged and hard. While the surgeons were considering whether a vaginal operation or a laparotomy offered the best hope of success, the patient solved the question for them by leaving the hospital. After the lapse of four years she was brought back, apparently dying from profuse hemorrhage. During defecation, a large rounded mass was extruded about eight inches from the vulva; this proved to be a myoma of the fundus of the now inverted uterus. An elastic ligature was at once applied to the base of the myoma, care being taken not to wound the peritoneum inside the inverted organ. The hemorrhage being thus arrested, the tumor was removed, and, antiseptic measures being taken, the uterus was replaced. The patient was ultimately discharged, cured.—*British Medical Journal*, August 21, 1886.

Bone Drainage in the Treatment of the Early Stages of Hip Disease.—At a recent meeting of the Surgical Section of the Academy of Medicine in Ireland, Mr. Stokes read a paper on this subject (*Dublin Journal of Medical Science*, August, 1886). The author commenced by alluding to the fact that hip excision is not maintaining the position in surgical estimation that other joint-resections occupy, which he believed to be due to a twofold cause—first, the rarity of the cases in which the disease is sufficiently limited to enable the disease to be completely removed; and second, the difficulty of maintaining fixation of the limb after the operation. He pointed out how very disheartening the statistics of the operation are, as shown by Dr. Yale and many German operators of eminence. He also showed that the results of the cases treated by methodical expectation, especially where suppuration in the joint occurs, are hardly more encouraging, and quoted Hueter's opinion that suppuration in the hip-joint is a "nearly absolutely fatal process." The principles of treatment that, as a rule, are mainly relied on were then discussed, and shown to be too frequently unsatisfactory. The author then discussed the views of Sir B. Brodie and others as to the pathology of the early changes in scrofulous hip disease, and inclined to the opinion that those held by that distinguished surgeon were correct—viz., that in the great majority of instances the primary changes consisted in an inflammation in the cancellous tissue of the bone, the result usually of a traumatism. The views of other surgeons and pathologists were then mentioned, notably those of Mr. Cooper Foster, Mr. E. Owen, and Mr. Hilton. Assuming that Sir B. Brodie's views were correct, the author drew attention to the desirability of giving an early exit to the inflammatory exudations in the cancellated tissue of the bone, and thought that could be best done by the manner recommended originally by Mr. Kirkpatrick—viz., by perforating the bone and freely applying potassa c calce along the tract of the wound of both the soft and osseous structures. In illustration of the advantages to be derived from this line of treatment, the author gave the details of three cases in which he employed it, and in which the results were very encouraging.

Treatment of Cystitis in the Female.—In a paper read before the Obstetrical Section of the Academy of Medicine in Ireland, by Dr. T. More Madden (*Dublin Journal of Medical Science*, August, 1886), the writer laid considerable stress on the efficacy (after the failure of milder measures in otherwise intractable cases) of freely dilating the urethral canal so as to cause a temporary incontinence of urine, and thus allow of the direct application of whatever local medication was deemed necessary to the endo-vesical mucous membrane. This plan of treatment Dr. Madden recommended as a substitute for Emmet's operation, or the formation of an artificial vesico-vaginal fistula in some cases; and at the same time he exhibited a new dilator, which he had designed and used for this purpose in many cases of cystitis.

The Oertel Treatment of Disorders of the Circulation.—It is not yet two years since Oertel published in Munich his new views on the treatment of disorders of the circulation, yet they have already met with a great amount of acceptance in Germany, and especially among medical men practising at the various baths, who, with very good reason, believe that such places offer greater facilities for carrying out this mode of treatment than can be enjoyed by patients living at their own homes.

Oertel's general idea is that, in many cases, owing to an accumulation of blood in the venous side of the circulation, the heart has more work to do than it can perform; and therefore his first object is to diminish the amount of work it has to perform by the reduction and regulation of the amount of fluid in the system. His second object is to repair alterations which have taken place in the respiratory and circulatory organs, and the further disturbances in the other organs connected with them, as far as is possible. It is a much simpler matter to effect the first than the second object. The only way of carrying out adequately such an abstraction of fluid consists in the energetic increase of the watery excretions, and in a correspondingly great diminution in the amount of fluid taken into the body, so that the loss of fluids through the skin and kidneys may no longer be covered by what is absorbed from the stomach and intestines, and that the superfluous amount of fluid in the body—partly in the blood-vessels, and partly in the tissues—may be brought down to a normal quantity. In short, the principle is—withdrawal of fluid, and introduction of only small quantities of it. Fluid may be withdrawn through the kidneys, or through the intestines; but it can be much more safely removed through the lungs and through the skin. Oertel's grand method of carrying out the latter intention is by

exercise in the open air, by ascending heights, and by active muscular exertion producing free perspiration. This is the marked recommendation of Oertel, and wherever there are hills at any health-resort patients are now advised to follow it; and rival stations compete for superiority in the advantages which they offer in this respect. Rapid excretion of fluid, however, can be produced more quickly than by exercise, by the use of hot-air and of vapor-baths, more especially of the former; and hence such baths, which are now to be found at most health-resorts, are recommended as a substitute, or, at all events, a supplement, to the hill-climbing cure. Of course, in such treatment special attention has to be directed to the condition of the heart; yet it is remarkable to what extent hot-air and vapor-baths have of late days been considered permissible in heart-affections; but it is agreed that they are entirely inapplicable in mitral stenosis, and especially in disease of the tricuspid valves or of those of the pulmonary artery, and also in affections depending on atheromatous disease of the aortic valves. The second means of diminishing the current of blood in the system is by cutting off supplies of fluid, by using a diet which shall improve the quality of the circulating fluid. The following are some of Oertel's directions about diet: There must be no long table d'hôte dinners; small quantities of nourishing food must be eaten more frequently. During the meal no fluid is to be taken. One hour, or an hour and a half, after meals small quantities of light, red, or white wine may be allowed; wine or water, if possible, to be iced in case of the patient complaining of thirst. Strong wine, tea, coffee, and beer are disallowed, unless specially ordered by a medical man. As to solid food, Dr. Oertel is liberal, and allows great variety. One must specially avoid fat, soups, potatoes, pastry, puddings, unless they are very light. He hopes by his regulation of the supply of fat, albumen, and hydrocarbons, to favor perfect digestion and perfect oxidation, and thus improve the blood. (It may be remarked, in passing, that Oertel's dieting is considered to be as effective in polysarcia as the Banting cure.) As to the second object, or the reparation of harm already done to the organs of circulation, something is supposed to be gained by the great improvement that has taken place in the blood, especially in its being less watery; but the greatest change is expected from muscular exertion. We have not space to follow Oertel into the detailed directions he gives as to walking and ascending hills, how the patient must not be tempted by the violent action of his heart to sit down and rest; how, on the contrary, he is to avoid sitting down, and remain standing, supported by his stick or by some fixed point, till the heart has become quiet. Further, the patient, when he has got through his prescribed distance, is not to sit down, but to remain standing until he turns to walk back. By such and by other strenuous exertions the muscles of inspiration are strengthened by deep inspirations; the alveoli of the lungs, before pressed together, are expanded again, and allow air to enter into them, and the functions of oxygenation to be performed. At the same time, exercise strengthens the muscular fibres of the heart, relieves it of a portion of its fat, and increases its power of working, which is aided by the improved character of the blood to be propelled. The various baths are vieing with each other in proclaiming the advantages they offer for hill-climbing; and at Baden and other stations an elaborate system has been introduced of marking the length and the degree of ascent of every path through the woods. Those who employ compressed-air chambers say that they produce analogous effects, and may be used with most advantage in the case of patients who are not able at first to take the strenuous exercise recommended. The use of compressed-air chambers produces a permanent expansion of the pulmonary space, relieves difficult breathing, and increases the depth of inspirations. During their use more oxygen is conveyed to the blood, the beats of the heart become slower, and the heart is strengthened. In these days the employment of muscles and kneading, or massage, going under the name of curative gymnastics, are in great favor; and a claim has been put in for them as subsidiary aids in expanding the thorax and strengthening the muscles of the heart and chest. Such is a general outline of the doctrines on the improvement of the circulation that are at present current in Germany. Of course, these views have not met with universal acceptance, but the general opinion on the subject is thus represented. A patient with an affection of the heart, who was formerly forbidden every exertion, who was to guard against any, even the slightest, excitement of the heart's pulsation, is now told to ascend hills, to excite his pulse—a proceeding which was formerly considered to be certain death, but which is now believed to strengthen the muscles of the heart. The patients suffering from accumulation of fat and from fatty heart, who were formerly ordered drinking cures exclusively, are now told, "Get rid of your water; be thirsty." These are rapid springs in practice, which everyone cannot take at once. But Oertel's principles will eventually be accepted by all. They carry with them such a stamp of truth and simplicity that it is impossible that they should not be correct. That the improvement to be gained by the use of this system should be permanent, it is necessary that the reduced and more solid diet shall continue to be adhered to, and the climbing of hills be continued. It need scarcely be added, considering the organs that are the subject of it, that this mode of cure is not to be lightly undertaken without the cognizance of a physician. With reference to the absolute novelty of the hill-climbing recommended by Oertel, it may be remembered that a somewhat similar exercise was prescribed some years ago to patients with pulmonary affections, but not when cardiac complications were known to be present. It remains to be seen how far the new system of treatment will stand the test of time and of experience. [illegible]

Ichthyol in Rheumatism.—Dr. Dubelir reports eight cases of rheumatism treated by ichthyol at the Moscow Military Hospital. Six of the cases were acute, and two chronic. The preparation was used both internally and externally. The affected parts were first washed off with soap and water, dried, and then smeared with the ichthyo-sulphate of ammonium, and covered with cotton or flannel. After long use, or when the skin was insufficiently or not regularly washed, pustules were caused by the application. Internally the author gave fifteen to twenty-five drops of the ichthyo-sulphate of ammonium in a wineglass of water, or else administered the remedy in the form of pills of one and a half grain each, from six to twelve pills a day. In every case the pains were quieted, but the swelling of the parts did not disappear. The writer advises, therefore, that ichthyol be given in rheumatism only for its anodyne effects.—*Russkaya Meditsina*, August 10, 1886.

Gelosine as a Vehicle for External Medication.—Gelosine is a mucilaginous principle extracted from the *gelidinum corneum*, a native of Japan. It is a colorless, amorphous, non-nitrogenous substance, which forms the basis of vegetable jellies. It is soluble in warm water, rendering solid on cooling five hundred and fifty times its own volume, the result being a fine transparent jelly, which is very slow to undergo putrefactive changes. M. Guérin considers that gelosine is admirably adapted for purposes such as poultices, vaginal and urethral suppositories, etc. The jelly undergoes gradual contraction, in which process any medicinal substance contained is slowly expressed until complete dessication is effected, thus bringing it constantly into contact with the skin. The only preparation needed is to dissolve gelosine in suitable quantity in warm water, and then add the medicinal agent, either in solution or in a state of fine division.—*London [illegible]*, July 15, 1886.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, September 25, 1886.

HEREDITARY DISEASE AND RACE CULTURE.

DR. GEORGE J. PRESTON contributes an interesting article with the above heading to the *Popular Science Monthly* for September. "Men have seemed," says the author, "to regard mental superiority as incompatible with physical perfection. They have rationally regarded the highest type of man as formulated in the old proverb, 'Mens sana in corpore sano,' but in their actual living have regarded it as an absurdity." The article strongly brings out the comparative estimate placed upon physical qualities by the ancients and by those of modern times. The old Spartans left all their weak and sickly offspring to die on the mountain-sides. In Athens, where the "state" idea was so strongly grounded, each man aimed at personal physical perfection, so that his services might be all the more valuable to the state. In those days the force of hereditary disease was scarcely felt. The first appearance of any taint caused its possessor to fall behind in the struggle. It was truly a survival of only the fittest.
